AUSTRALIAN ENCYCLOPAEDIA

THE ILLUSTRATED AUSTRALIAN ENCYCLOPÆDIA

Edited by
ARTHUR WILBERFORCE JOSE
Author of *A History of Australia from the Earliest Times*
and
HERBERT JAMES CARTER
President of the Linnean Society of New South Wales

VOL. I
A TO LYS.

AUSTRALIA:
ANGUS & ROBERTSON LIMITED
89 CASTLEREAGH STREET, SYDNEY
LONDON: THE AUSTRALIAN BOOK COMPANY
1925

All Rights Reserved

Wholly set up and printed in Australia by
Eagle Press, Ltd., Allen Street, Waterloo
1925

Registered by the Postmaster-General for transmission through the post as a book.

Obtainable in Great Britain at the *British Australian* Bookstore, 51 High Holborn, London, W.C.1, the Bookstall in the Central Hall of Australia House, Strand, W.C., and from all other Booksellers; and (*wholesale only*) from the Australian Book Company, 16 Farringdon Avenue, London, E.C.4.

PREFACE

THIS Encyclopaedia was first projected in 1912 as a historical and biographical record, under the editorship of Mr. Charles H. Bertie, Municipal Librarian at Sydney, and much material had been collected when the outbreak of war in 1914 temporarily halted its progress.

In 1917 work was resumed, and it was decided to include articles on scientific subjects also. For this section of the work we were fortunate to obtain the services of Mr. Herbert J. Carter, B.A. (Cantab.), F.E.S., President (1925) of the Linnean Society of New South Wales, who was able to secure the co-operation of the leading men of science in Australia. Their contributions are, in many instances, the first trustworthy summaries yet published of scientific knowledge previously accessible only in the journals of learned societies. In 1920 Captain Arthur Jose, just released from the Intelligence Branch of the Australian Navy Office, undertook the general editorship, and found that, owing partly to the lapse of time, partly to the opening up of fresh sources of information, it had become necessary to re-write much of the historical and biographical matter. Miss Persia Campbell, M.A. (Syd.), M.Sc. (Lond.), joined the staff in 1923.

These delays, however, proved beneficial in that they have enabled us to embody a great deal of information, both historical and scientific, that has but recently come to light. The utmost possible use has been made of original documents, especially of those contemporaneous with the events they describe; and for most of these we are indebted to the magnificent collection housed in the Mitchell Library at Sydney. Our work has been greatly facilitated, also, by the existence of two invaluable Commonwealth publications—the *Historical Records of Australia,* and the *Official Year Book of the Commonwealth.*

A special debt of gratitude for untiring help is due to Mr. Henry Selkirk, formerly keeper of archives in the New South Wales Department of Lands; to Captain Francis J. Bayldon, R.N.R.; and to the Principal Librarian (Mr. W. H. Ifould), Curator (Mr. Hugh Wright), and staff of the Mitchell Library. We are grateful also to the Trustees of the Australian Museum for granting the use of bird-drawings made by the late Neville H. P. Cayley; to Dr. Charles Anderson and the staff of the Museum for their personal help in ensuring accuracy; to the departmental officials of various States for help willingly rendered; to Dr. J. S. Battye (W.A.), Dr. Cumbrae Stewart (Q.), the late Mr. Thomas Gill (S.A.), Mr. A. W. Greig (Vic.), and Mr. Thomas Dunbabin (Tas.), for the general supervision of articles concerning their

respective States; to the Linnean Society of New South Wales for the drawings reproduced on pp. 152 and 715; to the authorities of the Sydney Technological Museum for permission to reproduce the coloured drawings of fishes; to Mr. William Dixson for help in solving difficult historical problems; and to innumerable correspondents for the patience and industry which they have exercised in furnishing the information we required.

We regret deeply the loss of much-valued contributors, notably of Professor W. A. Haswell, the eminent biologist; of Mr. Walter Jeffery, an indefatigable historian; of the Rev. W. W. Watts, the authority on Australian ferns; of Mr. H. G. Smith, F.C.S., and of Mr. W. J. Rainbow, F.E.S. Mr. Jeffery's articles have been revised by Captain Bayldon, and Mr. Watts's by Mr. Edwin Cheel. An article by the late T. F. Furber, on Geodesy, has been revised by Mr. D. S. Sawkins. The botanical matter generally is the work of Mr. J. H. Maiden, I.S.O., F.R.S., in collaboration with Mr. A. A. Hamilton. Most of the other articles bear the initials of their authors. For all other matter the editorial staff is responsible.

We take pride in publishing an encyclopaedia conceived, written, edited, printed and produced entirely within the Commonwealth of Australia, to the production of which the skilful and assiduous work of Mr. T. J. Bermingham of the Eagle Press has materially contributed.

ANGUS AND ROBERTSON

CONTRIBUTORS

A.H.S.L.	Arthur Henry Shakespeare Lucas, M.A., B.Sc., Curator of Algae in the National Herbarium at Sydney; formerly Headmaster of Newington College, Sydney, and of the Sydney Grammar School, and President of the Linnean Society of N.S.W.
A.M.	Anthony Musgrave, Entomologist to the Australian Museum, Sydney.
A.M.L.	Arthur Mills Lea, F.E.S., Entomologist to the South Australian Museum.
A.R.McC.	Allan Riverstone McCulloch, Ichthyologist to the Australian Museum, Sydney.
A.T.S.	Sir Archibald Thomas Strong, Kt.Bach., M.A., Litt.D., Professor of English in the University of Adelaide.
A.W.G.	A. W. Greig, formerly Hon. Sec. of the Historical Society of Victoria.
C.A.S.	Carl Adolph Von der Heyde Sussmilch, B.Sc., F.G.S., Principal of the Technical College, Newcastle; author of *Geology of New South Wales.*
C.B.	Christopher John Brennan, M.A., McCaughey Associate Professor of German and Comparative Literature in the University of Sydney.
C.H.	Charles Hedley, F.L.S., formerly of the Australian Museum, Sydney; Scientific Director of the Great Barrier Reef Committee.
E.A.B.	Edward Alfred Briggs, Lecturer in Zoology at the University of Sydney.
E.B.	Ernest Breakwell, B.Sc., Headmaster of the Agricultural High School, Yanco; formerly Agrostologist to the N.S.W. Department of Agriculture.
E.C.	Edwin Cheel, Curator of the Herbarium at the Botanic Gardens, Sydney.
E.M.O'B.	Rev. Father Eris M. O'Brien, formerly Professor of Australian History in St. Patrick's Ecclesiastical College, Manly; author of *The Life of Archpriest J. J. Therry.*
E.S.	Ernest Scott, Professor of History in the University of Melbourne.
E.W.F.	Eustace William Ferguson, M.B., Ch.M., Principal Microbiologist in the Department of Public Health, Sydney.
F.A.A.R.	Frank Alfred Allison Russell, M.A., Lecturer on Industrial and Commercial Law in the University of Sydney.
F.A.McN.	Francis Alexander McNeill, Zoologist to the Australian Museum, Sydney.
F.B.G.	Frederick Bickell Guthrie, F.I.C., F.C.S., formerly Chemist to the Department of Agriculture, Sydney, and Lecturer in Technology in the University of Sydney.
F.D.P.	Frederick Danvers Power, Consulting Engineer and P. N. Russell Lecturer on Mining at the University of Sydney.
F.J.B.	Francis Joseph Bayldon, Commander R.N.R., author of *Handling of Steamships during Hurricanes on the Coast of Queensland.*
F.M.C.	Frederic Morley Cutlack, Second Official War Correspondent with the A.I.F. in France in 1918-19.
F.V.P.	Rev. Frederick Vicary Pratt, M.A., Congregational Minister.
G.A.T.	George Augustine Taylor, Editor of *Building.*
G.A.W.	Gustavus Athol Waterhouse, D.Sc., B.E., F.E.S., Member of Council of the Linnean Society of N.S.W., and joint-author (with G. Lyell) of *The Butterflies of Australia.*
G.H.H.	Gerald Harnett Halligan, F.G.S., formerly Supervising Engineer for Harbours and Drainage in the Department of Public Works, N.S.W.
G.H.K.	Sir George Handley Knibbs, Kt.Bach., C.M.G., F.R.A.S., F.S.S., M.I.I.S., Director of the Institute of Science and Industry.
G.H.-P.	George Hendy-Pooley.
Gr.T.	Thomas Griffith Taylor, B.E., D.Sc., F.G.S., F.R.G.S., McCaughey Associate Professor of Geography in the University of Sydney; Senior Geologist with Scott's Antarctic Expedition, 1910-12, and leader of the Western parties.
H.A.L.	Heber Albert Longman, Director of the Queensland Museum.
H.B.	Harry James Burrell.
H.G.C.	Henry George Chapman, M.D., B.S., Professor of Pharmacology and Physiology in the University of Sydney.

H.G.S.	HENRY GEORGE SMITH (the late), F.C.S., formerly Assistant Curator and Economic Chemist at the Technological Museum, Sydney.
H.H.	HENRY HACKER, Entomologist to the Queensland Museum.
H.He.	HERBERT HEATON, M.A., M.Com., Professor of Economics in Queen's University, Canada; formerly Lecturer in Economics and Director of Tutorial classes in the University of Adelaide.
H.H.D.	HENRY HARVEY DARE, M.E., M.I.C.E., Chairman of the Irrigation and Water Conservation Commission of New South Wales.
H.J.	HOWARD JOSELAND, F.I.A., author of *Angling in Australia.*
H.J.C.	HERBERT JAMES CARTER, F.E.S., President of the Linnean Society of N.S.W., and Hon. Entomologist to the Australian Museum, Sydney.
H.J.F.	HENRY JAMES FORD, P.M., P.Z., etc.
H.W.P.	HENRY WILLIAM POTTS, F.C.S., F.L.S., formerly Principal of Hawkesbury Agricultural College, N.S.W.
J.C.	REV. JAMES COLWELL, F.R.H.S., author of *Methodism in New South Wales.*
J.C.D.	J. C. DAVIS, editor of the *Referee.*
J.Cr.	JOSEPH CROSSLEY, Marine Superintendent of the Adelaide S.S. Company, Ltd.
J.F.	JOHN M. FORDE.
J.F.S.	JAMES FARISH STEPHEN.
J.H.B.	JOHN HENRY BUTTERS, M.I.E.E., formerly General Manager of the Hydro-Electric Department, Hobart; now Chairman of the Federal Capital Commission.
J.P.M.	JOHN P. MONRO.
J.S.	SIR JOHN SULMAN, Kt.Bach., F.R.I.B.A., Vice-president of the Architectural Association of London, and of the New South Wales Institute of Architects.
J.S.B.	JAMES SYKES BATTYE, LL.B., D.Litt., Public Librarian of Western Australia, and author of *Western Australia; a History.*
J.T.	JAMES TURNBULL, formerly Manager of the Cootamundra, Rockhampton, and Geelong branches of the Union Bank of Australia.
J.V.C.-B.	JOHN VERNER CUNNINGHAM-BROWNE, formerly Chaplain in the Royal Australian Navy.
K.R.C.	KARL REGINALD CRAMP, M.A., F.R.A.H.S. Secretary of the Royal Australian Historical Society, and author of *State and Federal Constitutions of Australia.*
L.A.C.	LEO A. COTTON, M.A., D.Sc., Professor of Geology and Physical Geography in the University of Sydney.
L.H.	LAUNCELOT HARRISON, B.Sc., Challis Professor of Zoology in the University of Sydney.
L.O.S.P.	LESLIE OSWALD SHERIDAN POIDEVIN, L.R.C.P., L.R.C.S.
O.H.W.	OLIVER HOLMES WOODWARD, Assistant-Manager of Associated Smelters, Ltd., Port Pirie, S.A.
O.T.	OLIVER TRICKETT, of the Mining Museum, N.S.W. Department of Mines.
O.U.V.	OSCAR ULRIC VONWILLER, B.Sc., Professor of Physics in the University of Sydney.
P.B.	PIETRO BARACCHI, F.R.A.S., formerly Government Astronomer of Victoria.
R.G.S.	ROBERT GREIG SMITH, D.Sc., Macleay Bacteriologist to the Linnean Society of New South Wales.
R.J.T.	ROBIN JOHN TILLYARD, D.Sc., F.R.S., Head of the Biological Department, Cawthron Institute, Nelson, N.Z.
R.M.K.	ROBERT MATTHEW KIDSTON, author of *Lawn Tennis in Australasia.*
R.T.B.	RICHARD THOMAS BAKER, F.L.S., formerly Director of the Technological Museum, Sydney, and Lecturer in Forestry at the University.
R.W.B.	REGINALD WHEELER BRETNALL, formerly of the Australian Museum, Sydney.
S.H.R.	SIDNEY HERBERT RAY, M.A., F.R.A.I., Member of the Cambridge Anthropological Expedition, 1898.
T.C.R.	THEODORE CLEVELAND ROUGHLEY, Economic Zoologist of the Technological Museum, Sydney.
T.D.	THOMAS DUNBABIN, M.A., author of *The Making of Australasia.*
T.E.B.	THOMAS EDWARDS BURROWS, M.I.C.E., Chief Engineer of Harbours Branch in the Department of Public Works, Sydney.
T.G.	THOMAS GILL (the late), C.M.G., I.S.O., author of *Bibliography of South Australia, Colonel William Light,* etc.

T.G.T.	THOMAS GEORGE TUCKER, C.M.G., Litt.D., M.A., formerly Professor of Classical Philology in the University of Melbourne.
T.H.J.	THOMAS HARVEY JOHNSTON, M.A., D.Sc., C.M.Z.S., F.L.S., Professor of Zoology in the University of Adelaide.
T.S.	THOMAS STEEL, F.L.S., editor of *The Australian Naturalist.*
T.T.	THOMAS TOMBLESON.
T.W.E.D.	SIR TANNATT WILLIAM EDGEWORTH DAVID, K.B.E., C.M.G., D.S.O., D.Sc., F.R.S., *Emeritus* Professor of Geology and Physical Geography, University of Sydney.
W.A.B.	W. A. BLACKSTONE.
W.A.H.	WILLIAM AITCHISON HASWELL (the late), M.A., D.Sc., F.R.S., *Emeritus* Professor of Zoology, University of Sydney.
W.A.O.	WILLIAM ALEXANDER OSBORNE, D.Sc., M.B., Professor of Physiology in the University of Melbourne.
W.B.	WILLIAM BENSON, of the Society of Friends.
W.B.A.	WILFRID BACKHOUSE ALEXANDER. M.A., Scientific Controller of the Commonwealth Prickly Pear Laboratory and editor of the *Emu.*
W.B.S.	SIR WALTER BALDWIN SPENCER, K.C.M.G., M.A., F.R.S., D.Litt., D.Sc., Emeritus Professor of Biology, University of Melbourne; author of *Native Tribes of the Northern Territory of Australia,* etc.
W.H.	REV. WILLIAM HIGLETT, General Secretary of the Baptist Union of N.S.W.
W.J.	WALTER JAMES JEFFERY (the late), author of *Naval Pioneers of Australia,* etc.
W.J.R.	WILLIAM JOSEPH RAINBOW (the late), F.E.S., formerly of the Australian Museum, Sydney.
W.M.	WILLIAM MOORE, art critic, author of *The Beginnings of Art in Victoria, Studio Sketches,* etc.
W.R.S.	WILLIAM RAMSAY SMITH, M.A., D.Sc., M.D., Chairman of the Health Department of South Australia, author of *In Southern Seas.*
W.S.C.	WALTER SCOTT CAMPBELL, formerly Under-secretary to the Department of Agriculture, New South Wales.
W.W.W.	REV. WILLIAM WALTER WATTS (the late), F.L.S., a high authority on Australian ferns.

COAT OF ARMS OF THE COMMONWEALTH
(after the official design)

A

Abbott, EDWARD (1772-1844), was born in England, and after youthful service in the 34th and 73rd regiments joined the New South Wales Corps (q.v.) on 5 June 1789 (lieutenant, 1789; captain, 1795; major, 1808). Reaching Sydney on 28 June 1790, he was sent to Norfolk Island for service under Lieutenant-governor King, and became town adjutant, inspector of outposts and (apparently) a sort of informal government architect. After helping King to suppress an incipient mutiny in 1794, he returned to Sydney and in 1795 was made commandant of the Hawkesbury district, receiving at the end of the year a commission as magistrate. In 1796 he took despatches from Governor Hunter to London. Returning towards the end of 1799, he was in the following year appointed engineer and artillery officer, and planned the first battery on Middle Head and some constructive work in Dawes Battery (see MILITARY DEFENCE). The next few years he spent partly at Norfolk Island, partly as commandant at Parramatta, and in January 1808 joined the committee that deposed Governor Bligh (q.v.); he was chosen by his party to be the new judge-advocate, but resigned at once. In 1810 he was sent to England by Macquarie to attend the court martial on Colonel Johnston, and shortly afterwards his name was removed from the army list.

Returning to Australia in 1813, he was made deputy-judge-advocate in Tasmania, with considerable powers of summary jurisdiction, and filled this office with distinction. On its abolition he visited England again, returning with the appointment of civil commandant at Launceston, and thus held the position of acting-governor of the island while Arthur was on active duty with troops during the 'Black War' of 1830 (see TASMANIA). He died on 17 January 1844.

Abbott, SIR JOSEPH PALMER (1842-1901), son of John Kingsmill Abbott, was born at Muswellbrook in New South Wales on 29 September 1842. A pastoralist as well as a solicitor, he entered local politics in 1880 as member for Gunnedah, which constituency he left in 1885 for Wentworth; during that year he held office as minister for mines in the Stuart ministry (7 January to 7 October) and minister for lands in the Dibbs ministry (7 November to 22 December). In October 1890 he was chosen as speaker of the legislative assembly. He was a delegate from New South Wales both to the federal convention of 1891, as a nominee, and to that of 1897-8, as one of the ten elected members. He resigned the speakership in 1900, and died in September of the following year. (K.C.M.G., 1892).—His son, JOHN HENRY MACARTNEY ABBOTT, born in 1874, is a well-known writer, whose sketches of foreign travel (*An Outlander in England, Letters from Queer Street*) and historical novels are a part of Australian literature. He served with the 1st Australian horse in the South African war, and in May 1900 was commissioned a lieutenant in the royal field artillery; his account of the Australian achievements in that war (*Tommy Cornstalk*) ranks with the best war literature of its time.

à Beckett, THOMAS TURNER (1808-1892), second son of William à Beckett, solicitor, and brother of Sir William à Beckett, elsewhere treated, was born in London on 13 September 1808 and educated at Westminster School. In 1829 he was admitted a solicitor and attorney, and joined his father in practice; in 1850 he migrated to Victoria, was admitted a solicitor in 1851, and took an active part in the public life of the colony. From 1854 to 1887 he was registrar of the diocese of Melbourne, and for much of that period was also a member of council of the local university and a trustee of the public library. In 1852-5 he was a nominee

member of the legislative council, and in 1858 was elected by the Central Province to represent it in the new council—this seat he held until 1878; he was twice in office (without portfolio, 1860-1; commissioner of trade and customs, 1870-1), and in 1870 was chairman of an important royal commission on the civil service. He retired from political life in 1878, and from all public duties in 1887, and died on 1 July 1892.—His eldest son, THOMAS À BECKETT (1836-1919), was called to the English bar in 1859 and to the Victorian in 1860, was made a puisne judge of the Victorian supreme court in 1886, and frequently acted as chief justice. He died on 21 June 1919. (Kt. Bach., 1909.)

à Beckett. SIR WILLIAM (1806-1869), born in London on 28 July 1806, was the eldest son of William à Beckett, solicitor. Educated at Westminster School and trained for the bar, he was called in 1829, migrated to New South Wales in 1837, and for a short time edited the *Literary News*. In 1841 he was appointed solicitor-general of the colony, and in 1844 took a puisne judgeship and sat as primary judge in equity. In January 1846 he was transferred to the supreme court of the Port Phillip district, and, when that district became the colony of Victoria, was appointed its first chief justice. Ill-health forced him to resign in 1857; he returned to England in 1863, and died there on 27 June 1869. He is described by a contemporary (Edmund Finn) as cultured and intellectual, learned and impartial as a judge, charitable, tolerant, and an accomplished writer; but his extant writings are of no great value. (Kt. Bach., 1859)—His son, WILLIAM ARTHUR CALLENDER À BECKETT, born in 1833, was a figure in Victorian politics between 1868 and 1876.—His brother THOMAS TURNER À BECKETT is separately treated of. A younger brother, GILBERT ABBOTT À BECKETT (1811-1856), author of the *Comic History of England* and similar works, was a notable journalist of the early Victorian era, being on the original staff of *Punch*.

Aboriginal Languages. The existing material for the study of the aboriginal languages is of a very unsatisfactory nature. No exhaustive grammar of an Australian language has been published. Some of those with the fullest details are admitted by their compilers to be deficient; others contain internal evidence of the omission of many details. The best of the earlier grammars are the *Australian Grammar* of Threlkeld (1834), the Adelaide *Outlines* of Teichelmann and Schürmann (1840), the Western Australian *Descriptive Vocabulary* of Moore (1842), the Encounter Bay grammar of Meyer (1843), the Parnkalla grammar of Schürmann (1844), and the Murray River grammar of Moorhouse (1846), with those of Watson and Threlkeld (printed by Hale in 1844), and the Narrinyeri grammar of Taplin (1878). Much less satisfactory are Grey's notes on south-western Australian grammar (1840), Ridley's *Kamilaroi* (1875), Müller's grammar (1876-88), Gason's specimens of Dieri (1874), and the notes by Dawson and various writers on the Victorian dialects in Brough Smyth (1878). Fraser in 1892 reprinted Threlkeld's and Günther's grammars, and added one of Minyung. Among more recent works the Aranda of Kempe (1890), the Pittapitta (1897) and Kokoyimidir (1901) of Roth, and the Ngerrikudi of Hey (1903) leave little to be desired; whilst the notes of Planert on Aranda and Dieri supplement or complete those of Kempe and Gason. The *Report* of the Cambridge expedition to Torres Straits (1907) also deals in detail with the Mabuiag of the Straits and the Cape York languages. R. H. Mathews published short grammatical notes of a great many languages, but singularly failed to appreciate the necessity of a detailed account of the suffixes, which for the comparative study of languages like the Australian are most important. He gives usually only the number, gender and some cases of the noun, a brief account of the adjective, some forms of the pronouns (the interrogative and demonstrative often being without details) with the principal tenses of the verb and a few adverbs and prepositions. A few imperfect sketches of grammar are to be found in Curr, J. Mathew, and Spencer, and here and there in a few other places. Fairly full vocabularies, consisting usually of native word-lists with an English interpretation, accompany the grammars just named; in various books and journals there are many other vocabularies, which consist only of a limited number of English words with native equivalents.

Very few texts have been recorded in the native languages. The most extensive are those in Aranda and Loritya recorded by Strehlow. Some fragments of legends and songs appear in Brough Smyth, and others have been given by Mrs. Parker, Dawson, Taplin, Lauterer, J. Mathew, and Roth. Some specimens in Mabuiag are contained in the *Report* of the Cambridge expedition. The New Testament has been translated into Dieri by members of the Lutheran mission; the Bible Society has also issued translations of four gospels in Mabuiag and one in the allied Saibai. These represent the only effective translations in Australian languages. A portion of St. Luke's Gospel was translated into the language of the Lake Macquarie natives by Threlkeld, and into Wiradhuri by Günther; but these were only printed as literary curiosities long after the death of the translators and the disappearance of the tribes for which they were made. Some selections from the Scriptures in Narrinyeri by Taplin, and some paraphrases in Kamilroi and Dippil by Ridley, have also appeared. (Note that, though Ridley used the spelling 'Kamilaroi,' the shorter form is now generally adopted.) Part of the Church of England Liturgy was translated into Wiradhuri by Günther, and a few translations of prayers, etc., are found elsewhere.

UNITY OF THE SOUTHERN LANGUAGES.—Most of the earlier specimens of Australian languages were obtained from the southern parts of the continent, and it soon became apparent that a fairly large number of words were common to many vocabularies. The names for certain parts of the body, (head, ear, eye, nose, tooth, tongue, beard, hand and foot), some of the pronouns, and the numeral 'two' were especially prominent among these words. In the grammar, also, it was noted that the functions of words were indicated in all the languages by suffixes, and that such grammatical features as the dual number, the separate forms for 'we' to denote whether the person addressed is included or excluded, the declension of nouns, pronouns and adjectives by postfixes or post-positions, and the conjunction of verbs by suffixed particles, were common to all the languages; while sibilant sounds, the passive voice, and the higher numerals were absent. Thus the languages were very generally regarded as variants of one common form of speech, and proofs of their unity were adduced

by Grey, Moorhouse, and Latham, and generally accepted by late writers. The northern vocabularies published by Earl (1853-4) were too imperfectly known to become a disturbing factor; their diversity caused them to be set apart as Papuan. The non-agreement of the northern languages with those in the southern part of the continent, which was first indicated by W. Schmidt, has been confirmed since some languages of the Northern Territory and north-western Australia have become better known. Words of common occurrence in the south are not found in the northern languages; moreover, the northern vocabularies often show very little likeness between one language and another in the same region. In the Cape York Peninsula and in central Australia there is found a grammatical structure similar to that of the southern languages; but in the Northern Territory and north-western Australia the grammar is of an entirely different character. Functions of words are indicated by prefixes instead of suffixes; thus in Chowie we have *ngi nun-amur* I throw, *jou min-amur* thou throwest, where a southern language (Kamilroi) would have such an expression as *ngaia bumul-da* I beat, *nginda bumul-da* thou beatest. Some of the northern languages also show indications of a classification of nouns indicating gender, e.g. Kakadu; *roulu no-orkudua*, stringy-bark tree one male, *peindi wi-orkudua*, stone one female. Thus the Australian languages must be separated into two main divisions: (1) Northern Australian (Papuo-Australian), comprising the languages of north-western Australia, the Northern Territory, part of central Australia, and the Cape York Peninsula; and (2) Southern Australian (Australian proper), the languages of the remainder of the continent. It should be noted that the unity of the southern languages, so much insisted upon by early writers, is of a somewhat superficial character. It merely means that the vocabulary of any named language contains a certain number of words which are the same as, or similar to, those found in another language of the group, and that the word-formations and syntax are similar. But within this general likeness there is a great deal of variety, both in vocabulary and in formative particles; any one language is therefore generally unintelligible to the speakers of another, unless they are near neighbours. With regard to the northern languages, their great diversity in grammar and vocabulary shows that they must be regarded as an assemblage of distinct linguistic groups, with little or no relation to one another.

CLASSIFICATION OF THE LANGUAGES.—Classifications of the Australian languages were attempted by Curr and J. Mathew. Curr divided his collection of vocabularies into 22 books, each dealing with a separate region in which the languages were more or less related to each other. J. Mathew made a more precise grouping, based on the general characteristics of the languages and the distribution of certain words. A much more elaborate classification has been made by Schmidt. This is substantially the same as that of Mathew, though there is a difference in the order and arrangement of the groups. Mathew's arrangement of the southern languages is as follows:—

1. Victorian region embracing part of the Riverina in New South Wales, and the south-eastern corner of South Australia. This has two subdivisions: Eastern or Gippsland, and Western. 2. New South Wales and the south, centre, and east of Queensland. Subdivisions are, Eastern or Coast, and Western or Inland (west of the Dividing Range). 3. Western Australia and west-central Australia. Two subdivisions: North and South. 4. Languages of South Australia and east-central Australia: (including the west of New South Wales and the north-west of Queensland.

Schmidt classifies the southern languages thus:—

Division I.

1. The South-western Group (corresponding to Mathew's third group): (*a*) Yungar (in the south-western corner of Australia); (*b*) Central languages, (inland from west to south coast); (*c*) Luridya.

2. The South-central Group (corresponding to Mathew's fourth group): (*a*) Parnkalla-Tyura-Meyu sub-group; (*b*) Nulla; (*c*) Dieri-Yarraworka-Wonkamarra-Evelyn Creek sub-group; (*d*) The Darling languages; (*e*) Kana (western Queensland); (*f*) Koongeri-Birria.

3. Narrinyeri Group: (*a*) North; (*b*) South.

Division II.

Isolated Languages of the Upper Murray River District. (*a*) Lower Murray; (*b*) Murray Bend; (*c*) Murray, Darling and Lachlan Junction; (*d*) Bangerang; (*e*) Dhudhuroa; (*f*) Pallanganmiddah; (*g*) Emu-Mudjug; (*h*) The Victorian group. (These eight sections, with the Narrinyeri, correspond to Mathew's first group.) (*i*) Yuin-Kuri Group (coast of New South Wales from Victoria to 31° S.); (*j*) Wiradhuri-Kamilroi Group; (*k*) The East Coast Languages; (*l*) The North-central Group. (Of these (*i*) and (*h*) correspond to the Eastern, and (*j*) and (*l*) to the Western section of Mathew's second group.)

Mathew made one division of the northern languages: North Coast and Central Australia, including Cape York Peninsula and the north-west coast. Two subdivisions, Coast and Central.

Schmidt calls the same languages North Australian. He makes three divisions, according to the vocalic character of the final syllable: languages with words ending in any consonant; languages with words ending in r, l, n, ng, or m, or a vowel; and languages with an initial vowel and (in the north) possessing the sibilant.

In the first division he places nearly all the languages of north-western Australia and the Northern Territory; in the second, most of those in Cape York Peninsula; in the third, those of central Australia and the region towards the Gulf of Carpentaria.

PHONOLOGY.—There is no uniform system of orthography. Most of the earlier grammars adopted a system based upon Italian vowel-sounds and English consonantal-sounds; but in later works, and in a great majority of the vocabularies, words are spelled in all sorts of ways, without any indication of the sounds attached to the letters. Curr tried to get uniformity in his numerous vocabularies, but failed. His contributors 'spelt their vocabularies from the English point of view.' In many cases Curr substituted his own method, and thus added to the confusion. R. H. Mathews in his many grammars and vocabularies did not maintain a uniform orthography, even when dealing in different places with the same language. As an example of the vagaries of spelling the words given for 'fire' and 'water' by Curr in his 17 vocabularies of the Wiradhuri language may be quoted. 'Fire' is given as *ween* (seven times), *wunn* (three times), *wein* (twice) *wee* (twice),

win, we-ing and *waing.* 'Water' is *kaling* (twice), *kul'en* (twice), *kallee* (twice); also as *kalleen, galling, kalle, ka'ling, kalli, kullung, kaleen, kalun, karlin, karlee, gulli.* Other writers have written *wheen, wee-in,* and *we,* and *guleen, gulleen, culleen, cully, calleein, colleen, collin, cullie* and *calle.* In these circumstances the study of Australian phonology is beset with difficulties, which will not be removed until the sound-systems of some of the typical languages of each group have been properly studied, so as to form a proper basis for future enquiry.

The following sounds apparently occur in Australian languages.

Vowels: *a, (ah, a)*; *e (ay, ā, ai)*; *i (e, ee, y)*; *o (ow)*; *u (oo)*. These have the Italian sounds, the characters in brackets being often used in their place. Curr doubted the presence of the French *u*; but Schürmann uses *ü* (French *u*, German *ü*), and in the Northern Territory the German *ü* and *o* are both found.

Diphthongs: *ai (i, y)*; *au (ow, ou)*; *ao*; *ei*; *iu (u)*; *oi (oy)*.

Consonants: *k (c)*, *g*; *t, d*; *th, dh (dth)*; *ch (ty, tj, ts)*, *j (dy, ty)*; *r, r* Northumbrian), *l*; *y (i)*, *w*; *m*; *n*; *ng, n, nk, ngg*; *kw (qu)*. These are sounded as in English, *dh* being the *th* in 'the' and *ngg* the *ng* in 'finger.' The letters in brackets are often substituted. The guttural *ch* is said to be rare, but appears in Victoria and on the south-eastern border of South Australia. The guttural trill (Arab *ghain*, 'Melanesian *g*') seems to be described by Mathew as '*h* sharp, and clear like *r*.' The sibilants *s* and *z* are not found in the southern languages, but appear in the Cape York Peninsula and Mabuiag. The fricant *f* appears only in the Cape York languages; *v* also is rare. The aspirate '*h*' is apparently rare. Hartmann describes its sound in Victoria as equivalent to German *ch* in '*ich, mich.*' Taplin mentions '*h* sharp and clear' in Narrinyeri.

Combinations of Consonants. These are found in some of the languages—in Adelaide *rn, rl, dl, rt, nt, lt, rk;* in Kabi *br, pr, kr.* Such combinations are especially prominent in some of the northern languages, where we find such juxtapositions as *rr, rk, lk, rm, ly* (*y* consonant), *rb, ntr, fr, tr, rp, dp, tp, rk, lb, nb.*

Sound-changes. The sound-changes have not been properly studied. In some languages the surd and sonant consonants are said to be imperfectly differentiated; *k=g, t=d, p=b.* A few phonetic changes when particles are affixed have been noted in Wiradhuri, Narrinyeri, Adelaide and a few other languages. In this article no attempt has been made to rectify the vagaries of Australian spelling.

Grammar of the Southern Languages.—In morphology the Australian languages can hardly be said to fall within a single category. Though a large proportion of them are purely agglutinate, the assimilation of root and affix has brought others nearly to the inflectional stage. Thus in Wiradhuri we find that such suffixes as *-du* (genitive), *-di* (dative), are modified according to the terminal of the word to which they are affixed; e.g. *maddan-du* and *maddan-di* from *maddan,* wood; *balli-dyu* and *balli-dyi* from *balli,* boy; *inar-ru* and *inar-ri* from *inar,* woman. Friedrich Müller's statement that some Australian languages were at as low a stage as the formless languages of Further India (Burman or Siamese) was based only on imperfect examples of the south-western Australian dialects.

The nature of the root in Australian has not been thoroughly investigated. It appears to consist usually of one of two syllables. In forming words and in expressing their functions affixes are used, which themselves often consist of more than one syllable. In the southern languages suffixes are invariably used, in the northern prefixes, infixes, and suffixes. Reduplication does not appear to be a common feature. Expressing 'four' by a mere doubling of the word 'two' is the most common example. In Wiradhuri the reduplicated noun forms an adjective; in Kabi a partial repetition of a verb indicates intensity. Very few syntactical relations are expressed by position alone. The commonest are the position of the object before its verb, and the qualifying adjective after its noun.

Although in a sentence the distinction between noun and verb is quite clear, the facility with which nouns may be changed into verbs or adjectives, or verbs and adjectives into nouns, sometimes renders a rigid classification difficult. Thus in Narrinyeri (Encounter Bay) we have *tant-urmi* a bed, *tant-in* sleeping or to sleep; *pett-in* to steal, *pett-amalde* thief. The affix determines whether the word is noun or verb. Some languages distinguish persons from places and things, and employ different demonstratives or adjectives when used in apposition. Thus in Minyung *kumai* (large) is used to qualify animals and places; but with persons *kumaibin* is used for males, and *kumainagun* for females, while *kumainyon* or *kuminna* qualifies things. Some languages distinguish the feminine gender by a suffix; e.g. in Awabakal: *mulubinba-kal,* a male native of Newcastle, New South Wales; *mulubinba-kalleen,* a female ditto; in Wakka: *nyom* husband, *nyom-gun* wife. In Victoria: *amerjig* a white man, *amerjig-orok* a white woman.

Many languages distinguish the dual and plural of nouns by suffixes. In some the connection of the suffixes with the numeral 'two' and the adjectives 'few' or 'many' is plain; in others it is not apparent. Thus in Parnkalla: *yurralbelli* two men (*kalbelli* two), *yurru-rri* men (*kulbarri* three or several). Pittapitta: *kanari-pakoola,* two girls (*pakoola* two), *wungata-pityiri* women (*pityiri* is merely an affix).

The indication of the agent of a transitive verb by means of a suffix is very common, and in most of the languages the same affix denotes the instrument. Thus in Parnkalla: *Marralyi-nga ngai pittanarru kanya-nga,* boy me hit stone-with; Pittapitta: *yuppieri-lo kopena mali-lo kachea,* boy fish net-with catches. The genitive is commonly expressed by means of a suffix: Narrinyeri: *korn-ald menake,* man's beard; Kamilroi: *murri-gu burran,* man's boomerang.

In Pittapitta the genitive affixes vary according to whether the possessor and the possessed are persons or not; *koopakoopa-nga titi-wara,* old man's brother (*wara,* his), *koopakoopa-nga titi-wara-nga bibapooro,* old man's brother's boomerang; but *machoomba wapa,* kangaroo's pup, without suffixes. In many of the eastern languages this method appears to be common. The accusative generally appears without an affix, and is known by its position before the verb. Adelaide: *ngatto wodli taieta,* I house shall build. Wiradhuri: *mirri-du wille buddhe,* dog opossum bit. Most of the relations expressed in English by prepositions are indicated in Australian by nominal suffixes. These may not only show rest at, motion to and from, purpose, or origin, but express time, place, manner, direction, quantity and many other ideas. Some examples are:—

Parnkalla: *ngultapa-nga,* when he was a young man, *yara-lla,* as if he were a man, *mungkullutarri,* in the direction of the flagstaff. Wiradhuri: *Bidarai-bira-ndi,* from Bidarai's place. Narrinyeri: *tuni-watyeri,* full of sand. Pittapitta: *bibapooro-lo,* with a boomerang now, *moorra-ngo,* with a stick in the future.

Adjectives are often used as predicates, and are then conjugated as verbs. When used to qualify, they often take the same suffixes as the nouns to which they refer. Thus in Thurrawal: *nuggungai* I am good, *nuggumbi* thou art good, *nuggung* he is good, and so on in singular, dual and plural of all persons, tenses, and moods. In Kamilroi: *murri-du bura-lu burran-du kurrawile,* man big boomerang-with threw, *murri-gu bura-lu burran,* big man's boomerang, (*-gu, -lu,* genitive suffixes). As in the preceding example, the qualifying adjective usually follows the noun; but in some languages it precedes it.

Adjectives are often formed from the roots of other words by means of affixes. Thus in Kamilroi: *yul-arai* full, satisfied, *yul-ngin* hungry. Adelaide: *mai* food, *mai-tidli* provided with food, *mai-wadli* liberal with food, *mai-kudna* stingy. In some languages a kind of comparison is made by a suffix; more generally two positive statements are made. Parnkalla: *karra* high, *karralla* higher. Adelaide: *karru* high, *karra-intyerla* very high. Kamilroi: *murruba numma, nungurrage guggil,* good this, that (is) bad.

Words indicating place and direction are remarkable for their great variety, and it is to be regretted that they have not been more fully recorded. In the north-eastern and eastern languages they are often compounded with other words. Some Kamilroi examples are *ngowo* here, *ngurri* there in front, *ngutta* there on the right or down there, *ngurriba* there on the left or up there, *murra* there behind, *ngurribatai* from above. In Narrinyeri at least 30 words of this kind have been noted.

Australian pronouns usually distinguish the speaker, the person addressed and the person or thing spoken about. In the southern languages the inclusion or exclusion of the person addressed is indicated by the form of the first personal pronouns in the dual and plural. These may be distinct words, or the exclusion may be indicated by an affix to the inclusive form. Some examples of the first are:—Dieri: *ngaldra* you and I, *ngali* he and I (not you), *ngaiana* all of us, *ngaiani* we (not you). Of the second kind, Wiradhuri: *ngalli* you and I, *ngalliguna* he and I, *ngeani* we all, *ngeaniguna* we (not you).

In some languages the forms of the pronoun vary to indicate the relationship of the persons mentioned. Thus in Parnkalla, *ninna* is the ordinary pronoun 'thou,' but *nuro* means 'thou my father' or 'thou my child;' *ngadli* is 'we two' but *ngadlaga* means 'my mother and I;' *nuwalla* is 'you two,' but *nuwarinye* 'thou and thy son,' *pudlanbi* he and his wife. In Western Australia similar terms are very numerous. Some languages distinguish sex in the third personal pronoun. Thus Dieri: *nau* he, *nani* she. Minyung: *nguly* he, *nyan* she, *kully* he, she or it here, *mully* he, she or it there. Awabakal: *noa* he, *bountoa* she, (*bali,* we two) *bali-noa* he and I, *bali-bountoa* she and I. The third personal pronoun is often a demonstrative (this or that person or thing) and may thus indicate ideas of position. Some examples are:—Pittapitta: *nooie* he or it close in front or at the side, *nuaka* he or it or this close at the back, *nooari* he or it or that yonder. Awabakal: *ngali* he or this present, *ngala* that near, *ngaloa* that beside you.

In some languages the pronouns are said to express the verb 'to be,' and are inflected for tense or used as complete sentences. Pittapitta: *nŭjă,* I am or I was; *nŭnyō,* I will be. Awabakal: *ta,* it is; *tara,* they are.

In some of the Victorian languages the pronouns appear to consist of a noun with the possessive suffix, the noun-stem remaining in all persons and numbers. Thus in Woddowro:—

Bang-ik	I.	Bang-etuk-kollik	we three.
Bang-en	thou.	Bang-ud-kollik	you three.
Bang-nuk	he, she, it.	Bang-tana-kollik	they three.
Bang-ul	we two.	Bang-wodjok	we.
Bang-bullok	you two.	Bang-ud	you.
Bang-abulong	they two.	Bang-tanong	they.

The dual and trial of the pronouns often show traces of the numerals 'two' or 'three.' Thus *kollik,* in the Woddowro examples just given is the numeral three; and in Adelaide *purla* is they two, *purlaityе* two. Also Narrinyeri: *kengk* they two, *ninggengk* two. Kabi: *bula* two, and you two. Darkinyung: *bullabun* you two, *bulloara* they, *bulla* two. Western Australia: *boola* they two, but *goodjal* two.

The possessive pronouns are often formed from the same stem as the personal, and are sometimes identical with the genitive of the pronoun. The suffix used is generally different from that of the noun, and there is rarely any uniformity in the pronominal suffixes. The following table, in which the languages are arranged geographically from west to east, will give some indication of the variety in construction of the possessive pronoun:—

	I	my	thou	thy
W. Australia	nganya	nganalak	nginnee	nuncoluk
Parnkalla	ngai	ngaityе	ninna	nunko
Adelaide	ngali	ngaityo	ninna	ninko
Dieri	ngani	ngakani	jidni	jinkani
Narrinyeri	ngape	nganauwe	nginte	ngumauwe
Murundi	ngape	ngaiyo	ngurru	ngurrongo
Kamilroi	ngaia	ngai	nginda	nginnu
Wiradhuri	ngadhu	ngadyi	ngindu	nginnu
Woddowro	bangik	bangongik	bangen	bangongen
Darkinyung	ngaia	jannunggai	nginda	nginnunggai
Gundunggurra	goolangga	goolangooya	goolanjee	goolanyingoo
Thurrawal	ngaiagang	ngaiawooli	nyindigang	nyinduwuli
Awabakal	ngatoa, bang	enimoumba	ngintoa, bi	ngiroumba
Wakka	ngia	ngari	ngin	ngingori
Kabi	ngai	nganyunggai	ngin	nginyonggai
Pittapitta	nŭnjă	nŭnyătĭ	impă	ingkătĭ

The Victorian languages, some of the eastern languages and a few others also denote possession by means of a suffix.

	My boomerang	thy boomerang	his boomerang
Buandik	gettupgettup-main	gettupgettup-mun	gettupgettup-mung
Tyatyalla	gattimgattim-ek	gattimgattim-in	gattimgattim-uk
Thaguwurru	wangim-ik	wangim-in	wangim-o
Thurrawal	warrangan-dyen	warrangan-ngun	warrangan-hung

Pittapitta has different forms of the possessive, according to whether the possession is a person or thing: *Upperi* father, my father (no suffix), *pooti nunyati* firewood my, *titi mulla* brother thy, *bibapooro ingkati* boomerang thy. In all languages the pronouns are declined as nouns, often with the same suffixes. The distinction between the two forms of the nominative is as a rule only observed in the first and second persons singular of the pronoun.

Interrogative pronouns are analogous to the personal pronouns. There are usually words equivalent to 'What person? who?' and 'What thing?' For these expressions words based on

the syllables *ngan* and *mi* are very widely spread.

The verb is apparently rich in conjugational forms, but very few languages have been thoroughly investigated. The active verb is distinguished from the neuter, and each verb has various modifications to express reflective, reciprocal, continuative, causative or inchoative uses. These are usually distinguished by a change in the final affix, or by an auxiliary compounded with the principal verb. Some examples are:—Narrinyeri: *pingkin* to fall, *pinggen* to throw down, *nguldamul-mindin* to tire (compound of *nguldamulun* tires, and *mindin* to cause to be). Kamilroi: *ngummil* see, *ngummilmulle* to show (cause to see). Wakka: *buma* to strike, *bumjau* to strike another, *bumjinga* to kill (strike intensively). Parnkalla: *yabmirriti* to quarrel (*yabm-iti* to scold), *ngamma-ta* to run, *ngamma-ngutu* to cause to run, *ngammantutu* to continue running. In Wiradhuri there are a great many verbal formations of this kind, denoting various aspects of the action with regard to manner, time, place and accompanying circumstances. There are indications of similar constructions in other languages.

Moods and tenses are usually numerous, and are shown by suffixes to the stem. When followed by a suffix of number or person, these appear as infixes. Thus in Narrinyeri we have such forms as *lak* to spear, *laggelin* spearing, *laggelir* speared (participle), *lake* spear not, *lakilde* could spear, *lakkin* spear now, *lakkir* did spear, *lakemb* did spear long ago, *lakkani* will spear, *lakel* intend to spear, etc.

Except in the north-eastern and Victorian languages person is not indicated by the form of the verb. Many languages also use the same form for the singular, dual and plural, thus in south-western Australia: *nganya yening* I go, *bal yening* he goes, *ngela yening* we two go, *nō'ra yening* they go. Kamilroi: *ngai ngin-nuna ngummi* I you saw, *nginda ngunna ngummi* you me saw. But in Victoria person and number are indicated by the verb-ending. Thus in Tyatyalla: *takangul* we two (inclusive, i.e. you and I) beat; *takan* I beat; *takangulang* we two (exclusive, i.e. he and I) beat; *takar* thou beatest; *takawul* you two beat; *taka* he beats; *takabulang* they two beat; *takangukullik* we three (inclusive, i.e. you and I) beat; *takangu* we (inclusive) beat; *takandakullik* we three (exclusive) beat; *takandang* we (exclusive) beat; *takawa kullik* you three beat; *takawat* you beat; *takana kullik* they three beat; *takanaty* they beat. Similar forms are recorded in Gundunggurra, Thoorga, Thurrawal, and other languages of eastern New South Wales.

In other languages the change of suffix for person or number is only partial: in Darkinyung: *bondalittiwah* I eat, *bondalittiwi* thou eatest, *bondalittinoa* he eats, *bondalittinonda* she eats, but *ngullia bondalitti* you and I eat, *ngeang bondalitti* we eat—and so in other persons and numbers, which are only distinguished by the pronouns. In Parnkalla some numbers and persons of the verb are alike. Thus:—*ngai ngukata* I go; *ngadli ngukata* we two go; *ninna ngukata* thou goest; *nuwalla ngukamatta* you two go; *panna ngukatawo* he goes; *padlanbi ngukamatta* they two go; *ngarrinyelbo ngukata* we go; *nuralli ngukatanna* you go; *yardna ngukatanna* they go.

Simple and compound adverbs indicating time and place are very numerous. Many of them are plainly nouns with various affixes. The interrogative adverbs are formed usually from the interrogative pronoun 'What?'

Prepositions are not common, but appear in Victorian languages. Postpositions or affixed particles usually take their place. Certain names of positions are used in the Victorian languages with suffixed pronouns. Thus in Thaguwurru: *kallinudyik, kallinudyin, kallinudhu,* in front of me, thee, him; *wenyudyik, wenyudyin, wenyudhu,* behind me, thee, him. Sometimes the prepositional relation is included in the verb; Wiradhuri: *gulle* go up, *birrawa* go down.

The definite numerals are rarely expressed beyond 'two.' A few languages have a word for 'three,' but the usual expression is a compound of 'two' and 'one.' Examples of the numerals will be found in the notes on the several linguistic groups.

THE SOUTHERN LANGUAGES. In the notes which follow the order is mainly that of J. Mathew's classification, but for convenience' sake the subdivisions suggested by Schmidt have also been adopted.

1. *Victoria.* The largest linguistic group in Victoria was formed by the languages spoken in the north-west and central portions of the colony from the Goulburn and Broken Rivers in the north-east to the Wannon and Glenelg in the south-west, and from the Yarra in the south-east to Lake Hindmarsh in the north-west. A large number of tribal names have been recorded, many ending with the words *wurru* or *wurong,* or *tyalli* (meaning 'lip'), compounded with the word for 'no.' The following appear to be representative languages: (*a*) Burapa or Bureba (*burapper* no), in the north, from the Murray at Gunbower and Lake Boga to the lower Loddon at Boort; (*b*) Tyatyalla (Tatiara) and Buibatyalli in the north-west, from Lakes Werringen, Albacutya and Hindmarsh and the Wimmera River to Horsham; (*c*) Ngengenwurro, used on the upper Wannon and Glenelg above Sandford to the Tatiara country just over the border in South Australia; (*d*) Lewurru (*le,* no), on the Upper Loddon and Avoca Rivers from the Great Dividing Range to St. Arnaud, Mount Emu and the Wimmera at Glenorchy; (*e*) Thaguwurru (Thong-worong) in the north-east, along the middle Goulburn, westward to the Campaspe and eastward to the Ovens; (*f*) Wuddyawurru (Woddowrong, Witaoro) at Geelong, and on the western side of Port Phillip to Cape Otway and Ballarat; (*g*) Woiwurru (Wuiworong, Woeworong; *woe,* no), between the Hume Range and the lower Yarra as far as Melbourne; (*h*) Bunurong, in the south-east from Western Port to the upper Yarra at Healesville.

	one	two	ear	eye	hand	man
Bureba (Burapa)	kiarp	bullait	wimbuluk	minnuk	munnanuk	woitu
Tyatyalla	kaiup	bulaty	wurimbul	mirr	munya	wutyu
Ngengenwurro	kiarp	bullait	wimbuluk	minnuk	munnengnk	gole
Lewurru (Mt. Emu)	kiap	poolet	wirmbool	mir	munya	koolay
Thaguwurru	kôpthun	bulaubil	wirn	merin	mirnong	kulin
Witaoro	koenmoet	bullait	winguk	mirruk	munangin	koli
Woiwurru	kanbi	Lendyero	werring	merring	marnung	kulin
Bunurong	kop, koptun	polabel	werring	myring	munung	kulin

The Buandik (Bungandity) dialects were spoken in the south-west of Victoria from Lake Corangamite across the basin of Mount Emu Creek and the Hopkins, Eumeralla and lower Glenelg Rivers to Rivoli Bay and Mount Gambier in South Australia. They appear in three groups: (*a*) Buandik, at Mount Gambier and between Sandford and Dartmoor on the lower Glenelg. The Nundatyalli on the north towards Horsham apparently connects with the West Victorian; (*b*) Wanikin, at Mount Rouse and the Crawford, Wannon and upper Glenelg Rivers; (*c*) Dautgart: Hopkins and Eumeralla Rivers and Lake Condah.

	one	*two*	*ear*	*eye*	*hand*	*man*
Buandik	wondo	bolite	wrung	mir	murna	drual
Bungandity	wandho	boaity	wah	mir	murra	drual
Wanikin	kiup	polite	weerring	moeing	murrung	koloin, marah
Dautgart	koimoil	bulad	wing	ming	murrung	marra

Kolijon was a small tribe east of Lakes Colac and Corangamite. A few grammar forms and a short vocabulary show some likeness to the Buandik.

The Piangil dialects apparently connect the Burapa of western Victoria with the Wiradhuri of New South Wales. They are found under the tribal names of Wottiwotti (*wotti* no) at Swan Hill and Tyntynder, and Laitchilaitchi (*laitchi* no) at the junction of the Murray and Murrumbidgee.

	one	*two*	*ear*	*eye*	*hand*	*man*
L. Colac	—	buladduk	weinyeduc	mrinyeduc	macnyinuc	mondel
Kolijon	—	bulad	weregnennok	mirgnennok	mangennok	tharoong
Wottiwotti	kyup, yoori	pola	wirmpool	mirnoo	murnagna	woortongi
Laitchilaitchi	geyabi	boolagi	wimboola	mingi	munnagi	wooni

The south-eastern corner of Victoria from Anderson's Inlet to Cape Howe was the home of the Kurnai (*kurnai*, *kani* man). Five tribes are named by Howitt: Bra-tanolung (*bra* man), Bra-inkolang, Bra-brolung, Tatungolung, and Kroatungolung. Curr thought that there were 'probably six or seven distinct languages,' but only one, the Brabrolung (Brabirrawulung), is recorded. A different language appears in the east at Omeo. Specimens from Lake Tyers by Bulmer and from Lake Wellington by Hagenauer in Curr appear mixed with West Victorian. R. H. Mathews has a grammar of Brabirrawulung.

	one	*two*	*ear*	*eye*	*hand*	*man*
L. Tyers	kootopan	boolooman	wring	mre, mri	bret	brah, kanni
L. Wellington	—	—	wring	mooeh	pritt	kanny

Brabirrawulung	gutuban	bulaman	wring	mirri	brety	kunnai, bra
Gippsland (Howitt)	gootup	bullum	ooeng bunnumgurry	mree	prett narrungnung	kurni

2. *Narrinyeri.* The Narrinyeri is one of the better known languages of South Australia. It was spoken by the tribes living on Encounter Bay, the eastern side of Lake Alexandrina and the Lower Murray. There are good grammars and vocabularies by Meyer and Taplin. The vocabulary is distinct.

3. *The Lower Murray.* The languages along the lower Murray present a progressive divergence in grammar from Narrinyeri, with great differences in the vocabulary. The following names appear:—(*a*) Murundi, on the lower Murray from Wellington nearly to the North-west Bend; (*b*) at the North-west Bend a distinct language is found; (*c*) Kemendok, the language of the Yerreyerre tribe about Mildura; (*d*) Yittha, about the junction of the Lachlan and Murrumbidgee. The Murundi is represented by a grammar. It shows some resemblance to Narrinyeri, but the affixes usually differ.

4. *The Upper Murray.* The basin of the upper Murray and its tributaries was apparently occupied by tribes whose languages, though distantly related, differed very greatly in vocabulary from those north and south of them. These languages were the following: (*a*) Dhudhuroa, in the basins of the Mittamitta and Kiewa Rivers as far as the Murray between Albury and Jingellic; (*b*) Emu-mudjug, about Barnawatha, west of Albury; (*c*) Bangerang, from Deniliquin southward to Echuca and the basin of the Goulburn. Curr gives the Toolinyagan as one of the Bangerang tribes, and R. H. Mathews calls them Yotayota; (*d*) Ngarrimowro, north and south of the Murray at Yulima. This is said to be related to Bangerang; (*e*) Pallanganmiddah, west of the Kiewa River and south of Emu-mudjug. The grammar of these is known only from short notes.

	one	*two*	*ear*	*eye*	*hand*	*man*

5. *The Wiradhuri and Kamilroi.* A group of allied languages, of which the Wiradhuri and the Kamilroi are the best-known, occupy a very large area in central and southern New South Wales. They extend westwards from the Blue Mountains and New England beyond the Bogan and Lachlan, and thus occupy the basins of the Lachlan, Murrumbidgee, Bogan, Castlereagh,

Namoi, Gwydir and Dumaresq rivers, and of the Moonie and Culgoa, north of the Barwon. The main divisions are: (*a*) Wiradhuri (Wirajuri, etc.), in the south-east, from the Murray about Deniliquin and Albury across the Murrumbidgee to the upper Bogan, Macquarie and Castlereagh; (*b*) Wongaibon, on the middle Lachlan and northwards to the Bogan; (*c*) Wailwun, in the north, along the Barwon valley from Brewarrina to Walgett and southwards about the lower Castlereagh and Mara; (*d*) Ngeumba, on the lower Bogan; (*e*) Burrabinya, on the Bokhara and Culgoa, north of the Barwon; (*f*) Kamilroi, in the north-east from Walgett over the Liverpool Range southwards to the Goulburn and Upper Hunter, including the basins of the Namoi (Liverpool Plains) and Gwydir; (*g*) Yualeai (Euahlayi, Yowalleri), Nguri and Wirriwirri in the north, from Bourke and Walgett across the Barwon, Bokhara and Culgoa into the basins of the Moonie and Weir in southern Queensland. With the exception of the Nguri and Wirriwirri, all these languages are well illustrated by grammars and grammatical notes.

Wirriwirri	—	—	pinna	meel	myya	—

6. *Coast Languages of New South Wales.* In eastern New South Wales the distribution of the languages is determined by the ranges parallel to the coast. There are two well-marked sections, one in the north, the other in the south, for which Schmidt proposes the names *Kuri* and *Yuin*, from the words for 'man' common to each group.

The following languages represent the northern group (Kuri):—(*a*) Bripi, at Port Macquarie and on the Hastings and Wilson; (*b*) Kutthung, on the coast near Port Stephens; (*c*) Awabakal, at Newcastle and Lake Macquarie; (*d*) Wanarua, from Maitland to the Liverpool Range; (*e*) Darkinyung, on the Hawkesbury and Broken Bay, and inland to the Hunter; (*f*) Dharruk and Gundunggurra, from the mouth of the Hawkesbury to Mount Victoria and south to Berrima and Goulburn (Dharruk on the coast, Gundunggurra inland); (*g*) the Port Jackson language. The Awabakal was the subject of the first Australian grammar by Threlkeld, who also published many illustrations of its structure. R. H. Mathews has published notes on Darkinyung, Dharruk, and Gundunggurra.

Gundunggurra	meddung	bulalli	—	—	—	(murrin) (bowwil)
Port Jackson	wogul	boola, yublowre	gorai	mi	tamira	mulla, cora

The following languages appear to represent the southern group (Yuin):—(*a*) Thurrawal (Turruwul), from Port Hacking and Botany Bay to Jervis Bay, including the Wodiwodi about Wollongong and Illawarra; (*b*) Tharumba (Muruya), about the Shoalhaven River, north of Jervis Bay; (*c*) Ngunawai, inland from Goulburn and south-west to Yass and Lake George; (*d*) Thurga, on the coast south of Jervis Bay as far as Bermagui; (*e*) Dyirringan, south of Thurga to the Victorian border; (*f*) Ngarrugu (Ngarago), inland to the Monaro district and from Omeo to Queanbeyan. All these languages have been the subject of short notes by R. H. Mathews.

Ngarrugu	bur, burē	bulala	dyanyange	gundthul	murrungga	baual

7. *The Eastern Languages.* A number of very slightly connected languages are spoken in the east of New South Wales and Queensland, between the mountains and the coast. The following are the main groups in New South Wales, beginning from the south:—(*a*) Thangatti, spoken on the lower Macleay north of Bripi; (*b*) Kumbainggeri, on the coast from Nambucca to Grafton and the Clarence; (*c*) Yukumbul (Yookumbil, Yukomble), in New England about Glen Innes and Tenterfield, and inland from Minyung; (*d*) Minyung, on the Richmond and Tweed Rivers. Three dialects are named: (1) Nyung on the Richmond, upper Clarence and Tweed; (2) Ngando on the Tweed and at Point Danger; (3) Northern, on Darling Downs and along the Albert; (*e*) Pikumbul (Begumble, Bigambel), at the junction of the Macintyre and Dumaresq, and on the Weir (on the border of Queensland and New South Wales); (*f*) Murrawarri. This language, spoken far inland between the Culgoa and Warrego Rivers, is assigned by Schmidt to this group.

MEDICINE MAN EXTRACTING EVIL MAGIC (NORTHERN TERRITORY)

GROUND DRAWING CONNECTED WITH A SNAKE TOTEM (NORTHERN TERRITORY)

PREPARING FOR A CORROBOREE (CENTRAL AUSTRALIA)

The main groups in Queensland, beginning from the south, are:—(*a*) Turrubul, at Moreton Bay and along the Brisbane River. Somewhat doubtfully related to this is the Guwar language of the Wogee tribe on Moreton Island, and the Jandai language of the Goenpul tribe in the centre and south of Stradbroke Island. The Jagara language of Lauterer also seems related; (*b*) Kabi dialects, spoken over the Burnett and Wide Bay districts, and on the coast and islands from Bustard Bay to the north side of Moreton. There are numerous dialects. J. Mathew gives a grammar from Mary River, and Ridley notes on the Dippil of Moreton Bay; (*c*) Wakka dialects, used about the Great Dividing Range along the upper waters of the Dawson and Condamine. There are several dialects. J. Mathew gives a grammar of the language about the upper Brisbane. The Merooni, used at Bustard Bay, is similar; (*d*) Bieli, an imperfectly known but distinct language, used on the coast from Keppel Bay to Port Curtis, and inland to Calliope; (*e*) The Broad Sound, Marlborough, Rockhampton and Yaamba language appears in this group; (*f*) The tribes at Halifax Bay, on Palm, Hinchinbrook and Cardwell islands, and on the upper Herbert, are said to speak one language. Curr enumerates several tribes with names ending in *bara* or *burra*. Cleveland Bay specimens show a different dialect.

8. *Central Queensland.* A number of related languages are found in central Queensland in the region between the upper waters of the Thomson, Barcoo, Paroo, Warrego and Maranoa on the south, and those of the Diamantina and Burdekin and the Cook district on the north. Languages representative of the western group are:—(*a*) Kungeri. This includes the Kungeri on the upper Thomson and Barcoo; the Kungarditchi, east of the Thomson; and the Birria, west of the Thomson below Jundah; (*b*) Kogai or Kogurre, from the upper Paroo and Warrego eastward; (*c*) Barcoo. From the Barcoo to Tambo on the Nogoa the dialects fall into two not very distinct divisions. One is represented by the Yangeeberra on the Barcoo, the other by the Bimurraburra on the Nogoa River. Barcoo and Kogai are connected with Goa by a mixed language used about the Alice and Mount Enniskillen; (*d*) Goa, on the upper Diamantina and Hamilton, and on Middleton Creek; (*e*) Puruga, from Cornish Creek on the upper Thomson north-west to the upper Flinders and north-east to Cape River; (*f*) the Cook district languages continue the Puruga northward to the Walsh and Gilbert, and to the northern languages.

The eastern group may be represented by:—(*a*) Briaba, the language about the upper Burdekin and Clerke and southward to Bowen Downs. Oriba Kulba, at Mount Black, is different; (*b*) Eneby. This is said to be the language of a number of tribes in the basin of the Cape River, on Porter's Range, and about Charters Towers and Natal Downs. Many of the tribal names end in 'burra:' Pegullo-burra, Yucka-burra, Wokul-burra, Koombokka-burra; (*c*) Yuipera (Port Mackay Group). East of the Eneby-speaking district a number of tribes with names ending in 'burra' appear to have reached the coast. Their district lies along the Mackenzie and Isaacs rivers, northward to Fort Cooper (Nebo), Mackay and Port Denison. The Nebo tribe is known as Aminungo.

9. *West Australian.* Only one language appears to have been spoken in that portion of Australia which lies south-west of a line drawn from the west coast near Mount Peron to the south coast at Esperance Bay. The numerous vocabularies show very little difference between dialects. The grammar is fairly well-known, and a few texts have been published.

	one	*two*	*ear*	*eye*	*hand*	*man*

Pinjarra	dūmbart	gugal	dwanka	mail	murra	nungar
Newcastle	kain	guchal	dwanga	meal	mara	yunger, mamerup

10. *West Central Australian.* A chain of connected languages stretches across western Australia in a diagonal direction from the north-western and western coasts between the De Grey and Swan rivers to the southern coast between Cape Pasley and Streaky Bay. The representative languages appear to be:—(*a*) Ngurla (De Grey River), Widukari (Shaw River), the language used at Nickol Bay, and Kakarakala (North-west Cape), all on the west coast; (*b*) Majanna (Shark Bay), Eaw (Northampton), and that used at Champion Bay on the west coast; (*c*) Muliara (upper Sandford), Natingero (200 miles north-east of Newcastle), and the dialects of the Gascoyne and the upper Murchison; (*d*) Mining (inland from West Australian, in the Fraser Range and on the south coast between Point Culver and Eucla); (*e*) at Streaky Bay and Marachowie the language appears mixed with Parnkalla.

11. *Luritcha.* The Luritcha (Loritja, Aluridya) is spoken on the borders of Western and South Australia and in the Everard and Musgrave Ranges, as well as in the Blyth Range and about Lake Amadeus. The people are in contact with the Aranda, but differ entirely in language. No grammar is published, but abundant material has been provided by Strehlow. As in Aranda, a peculiar speech is used in mystic ceremonies.

12. *South Central Australian.* The languages of South Australia south of Lake Eyre form two groups, one north, the other south of Lake Torrens. In the northern group several apparently distinct languages are found, of which the following are representative:—(*a*) Wangarabunna, spoken around the western, northern and southern shores of Lake Eyre; (*b*) Dieri, from Lake Eyre eastward along Cooper's Creek. The language used on the Warburton (Ominee) is similar. We have two Dieri grammars and a translation of the New Testament into Dieri; (*c*) Yarrawurka (Yowerawoolka, Yandrawandra), on Cooper's Creek, Coony Lake and Mulligan River; (*d*) Pono (Evelyn Creek), and Mulyanapa, in the north-west corner of New South Wales; (*e*) Wonkamarra, on the lower Bulloo River in south-west Queensland.

Of these languages Dieri and Pono show a connection with the languages of west central Queensland, and Wonkamarra with the eastern languages.

	one	*two*	*ear*	*eye*	*hand*	*man*
Wangarabunna	muyu	parculu	yarri	milyardi	murra	nulla

Wonkamarra	tharranya, warra	barcōōla	bina, pinna	mongura	murra	ura, ngoora

The languages used round Spencer Gulf appear to form three related sections:—(*a*) Parnkalla, at Port Lincoln, on the western shore of Spencer Gulf and generally throughout Eyre Peninsula, south-east from Streaky Bay and the Gawler Ranges; (*b*) Tura, north of Spencer Gulf and east of Lake Torrens. This language appears under several tribal names—Arkabatura (70 miles north of Port Augusta), Kooyiannie and Unyamootha (Beltana), Kortabina (east shore of Lake Torrens), Tura or Eura (Mount Serle), Nimbalda (Mount Freeling)—and connects Parnkalla with Meyu; (*c*) Meyu, on the eastern shore of Spencer Gulf, Yorke Peninsula and the Adelaide district.

Adelaide	kuma	purlaitye	yurre	mena	mara	meyu
Yorke Peninsula	ariekoo	bulli	daltie	minna	mirra	nipoo

13. *East Central Australian.* In this division the Darling languages may be distinguished from those of western Queensland. A number of closely associated languages are spoken over a wide extent of country in the valleys of the Darling, lower Paroo and Warrego, and towards the Barrier Range, where they connect with Parnkalla and Yarrawurka. The following names appear:—(*a*) Marowra on the lower Darling, north-west from Menindee and Wilcannia; Milya-uppa on Torrowotto Lake, and Parooinge on the lower Paroo, appear to speak the same language; (*b*) Kurnu, on the Darling from between Tilpa and Louth northwards to

Bourke, and on the lower Warrego; (*c*) Bahkunji (Bahkinji). A vocabulary under this name in Curr shows the same language as Kurnu; but Cameron gives a list in Bahkinji (along the Darling to Menindee) which shows relationship to Kungĕri on the South Australia-Queensland border; (*d*) Baddyeri, from Yantabulla to Hungerford and Thargomindah.

	one	*two*	*ear*	*eye*	*hand*	*man*

Baddyeri	kurritya	bulunna	yuri	mainyu	marra	kurna

A number of related languages are spoken in western Queensland from Middleton Creek (on the upper Diamantina) across the Hamilton and Georgina junction to the Mulligan. The following are representative:—(*a*) Pittapitta, on the Burke, Hamilton and Georgina rivers (this appears under various names in Roth and Curr); (*b*) Ulaolinya, west of Pittapitta on the upper Mulligan; (*c*) Wonkajera, north of Ulaolinya; (d) Miorli (Myallee), on the upper Diamantina; (*e*) Karawalla, on the lower Diamantina.

Pittapitta has been studied by Roth. It shows several peculiarities of grammar, especially in the pronouns, which indicate gender, locality and time, as well as case, and singular, dual and plural number.

	one	*two*	*ear*	*eye*	*hand*	*man*
Pittapitta	oorooroo	pakoola	nara	mē	murra	kana

Miorli	oorooroo	pakoola	nara	unga	murra	kana
Karawalla	orroo	barkoola	nuri	miiki	murra	kerna

14. *North-west Queensland.* A great many vocabularies have been collected in the region (between the Great Dividing Range and the Gulf of Carpentaria) which includes the basins of the Leichhardt, Cloncurry and Flinders. In the absence of grammar notes, the dialects are difficult to classify. The representative languages appear to show four sections:—(*a*) Wunamurra (Oonamurra), on the upper Flinders and Saxby; (*b*) Mitakudi, on the Cloncurry; (*c*) Miape and Mikulon, between the Cloncurry and Leichhardt; (*d*) Mikadūn, on the Leichhardt.

	one	*two*	*ear*	*eye*	*hand*	*man*

Mikulon	deinba, moar	blakara	benarr	mille	mambilla	eerman
Mikadūn	wongarri	kurbayla	binna	tibarri	malla	yirrman

The Northern Languages. The justification for separating the northern languages of Australia from those of the south consist mainly in (*a*) the great variations in vocabulary, which indicate independent languages, (*b*) the use, in the west and centre of northern Australia, of grammatical methods entirely foreign to the southern languages e.g. prefixes and infixes, and (*c*) the absence in many northern languages of the distinction between the inclusive and exclusive personal pronouns. Schmidt's classification has been already mentioned, but in what follows a geographical arrangement is adopted. A few notes on grammar are added, when this differs from that of the southern languages. Five regions may be distinguished: (1) Cape York Peninsula; (2) Carpentaria; (3) Aranda; (4) Northern Territory; (5) North-western Australia.

1. *Cape York Peninsula.* The languages of Cape York Peninsula do not diverge very widely from the southern languages in grammar, but differ so much from them in details and in vocabulary, that it is expedient to class them (at least provisionally) as a distinct division. In the south of the peninsula some mixture with southern languages is evident. The following language-groups appear: (*a*) Mabuiag, on the western islands of Torres Straits (the speakers of this language are physically Papuans, and the northern island, Saibai, is close to New Guinea); (*b*) The Cape York group, comprising Yaraikāna, on the western side of the Cape; Ngerrikudi, on the Batavia, Mapoon and Coen Rivers; Gudang, on the eastern side of the Cape; and Otati, at Cape Grenville; (*c*) Weymouth Bay; (*d*) Princess Charlotte Bay; (*e*) Koko-yimidir and Bulpoonara, from Weary Bay and Endeavour River to Cape Flattery, and probably inland to Granite Range and Bloomfield Valley; (*f*) Mirkin, on the Palmer River, and Koogoominny, on the Mitchell River; (*g*) Queeariburra, on the Lynd River; (*h*) Walsh River; (*i*) Mount Elliot, Cape Cleveland, and the mouth of the Burdekin.

	one	*two*	*ear*	*eye*	*hand*	*man*
Mabuiag	urapun	ukasar	kaura	dan	get	mabaeg
Yaraikana	ipima	orima	ewoi	annga	mata	ama
Ngerrikudi	pema	ambute	woa	adae	a	ma
Gudang	pirman	ilabiu	iwunia	ratair	ata	imbamoyu
Otati	wema	aroma	ewoi	yciti	ara	baiala
P. Charlotte Bay	—	—	yimpa	toontree	boolom	—
Koko-yimidir	nobun	godera	milka	mil	mangal	bama
Bulpunarra	nobin	mummera	mitkabuggir	meil	murra	bumma
Granite Range	nupun	mumurra	binna	mee-i	murra	pumma
Bloomfield Valley	nupoon	marmara	milger	mil	mara	dingar
Mirkin	appool	impa	innur	immun	irre	immi
Koogoominny	apul	yirnpa	enar	emun	—	parma, jimmi
Queeariburra	nyana	nuyuona	—	—	—	murri, mali
Walsh River	gatim	bul	wi	lipwar	dhi	lunjin
Mount Elliot	woggin	boolray	deeragun	teeburra	kabankaban	munya
Mouth of Burdekin	warrin	blarin	kungun	deebara	wurrumby	dulgooh

The grammars of Mabuiag, Yaraikana, Ngerrikudi, and Koko-yimidir are fairly well-known, but none of them shows any wide divergence in type from the southern languages. Those in the north distinguish the inclusive and exclusive pronouns. In Mabuiag the verbal root has an indefinite signification, which is rendered definite by a prefix. Thus *palai*, separate, cut into, split; *adaka-palai*, to let out (*adaka*, to the outside); *dan-palai*, live, open eyes (*dan*, eye); *minar-palai* write (*minar*, mark); *poi-palai*, shake off dust (*poi*, dust).

2. *Carpentaria.* South of the Gulf of Carpentaria several languages are recorded, with entirely distinct vocabularies and unknown grammar. These are (*a*) Karrandee, on the Gulf of Carpentaria, from the Bynoe River to the Norman and inland; (*b*) Wollongurmee, from the mouth of the Norman to the hills below Cambridge Creek; (*c*) Yangarella, on the eastern side of the Nicholson, to the coast; (*d*) Mingin (Minkin), at Burketown and west of the Leichhardt; (*e*) Leeanuwa, on the McArthur at Borroloola; (*f*) Kalkadoon, on the Barkly Tableland and Selwyn Range; (*g*) Walookera (Elukera), on the upper Georgina from Roxburgh to Carondotta; (*h*) Yanda, at the head of the Hamilton; (*i*) Yelina, on the Burke.

	one	*two*	*ear*	*eye*	*hand*	*man*
Karrandee	lum	bugar	nulliak	ale	maar	aam, ngaan

3. *Aranda.* Aranda and its dialects are spoken over a considerable area in central Australia, from the Georgina in western Queensland westward to the Macdonnell Range, the Finke, and the Peak in South Australia. The main divisions are:—(*a*) Yaroinga, in the north-east on the upper Georgina from Lake Nash to Gordon Creek; (*b*) Undekerebina, in the Toko Ranges; (*c*) Plenty and Marshall rivers in the north-east; (*d*) Aranda, in the west in the Macdonnell Ranges, on the Finke, and at Charlotte Waters and Alice Springs; (*e*) Wychinga, in the south-west on the Macumba.

The grammar is of a type similar to South Australian, but the pronouns, particles and vocabulary are absolutely distinct. The pronouns will serve as examples:—Common, singular: (1) *ata, ja, jinga;* (2) *unta, nga;* (3) *era, nala.* Mystic, singular: (1) *anua;* (2) *rankaltya;* (3) *allya.*

	one	*two*	*ear*	*eye*	*hand*	*man*
Yaroinga	âwoonyĕrā	ŭttĕrā	elpă	ŭngă	eljă	ŭrtwa
Undekerebina	âwŏnyĕrā	ŭttĕrā	yālbă	ŭlknă	yĕlkă	ŭppreellă, yĕlkă
Plenty River	—	—	—	elguma	ildya	—
Aranda	minta	tara	ilba	alkna	iltya	atua
„ , Mystic	knanyinta	tnalanga	tauana	reoara	beanga-kurka	ndoaritya
„ „	tyurura	tnalanga	ngarinya	mbakara	remba	antapara
Wychinga"	ninta	dramma	ilpŭkita	ugnaquirta	ilcha	adninga, arrilla

Aranda is one of the best-known languages of Australia. There are grammars by Kempe and Planert, vocabularies and texts by Strehlow, and a sociology by Spencer and Gillen.

4. *The Northern Territory.* Spencer and Gillen name more than 50 tribes of the Northern Territory. For most of these the only language-specimens are the numerals, a few relationship-names and very short vocabularies. The following grouping is provisional and partial:—(*a*) Melville Island; (*b*) Worgait, on peninsula west of Port Darwin; (*c*) Larrakia, at Port Darwin; (*d*) Warrai group, consisting of Woolwoonga, on the Adelaide; Warrai, between Port Darwin and Pine Creek; Awarra (?); Aggrakundi, near Pine Creek; (*e*) Djauan, on the Katherine and at the sources of the Daly and Roper; (*f*) Mungarai, on the middle Roper; (*g*) Yungman, on Elsey Creek; and Waduman, on the Roper; (*h*) Nullakun and Mara, both south of the Roper; (*i*) Mullukmulluk, Ngolokwanggar, Daktyerat, on the Daly; (*j*) Mudburra, on the upper Victoria; (*k*) Umbaia, north of Powell's Creek; and Umbria, at Anthony's Lagoon; (*l*) Kakadu, between the east and west Alligator Rivers; (*m*) Binbinga, between the McArthur and the Robinson, on the Gulf of Carpentaria; (*n*) Tjingili, east of the Robinson; Chingalee, between the Katherine and Tennant's Creek; (*o*) Coburg Peninsula Group, comprising Limbakaradja or Yarlo (*yarlo,* no), Port Essington; Oitbi (*oitbo,* no), Van Diemen Gulf; Jalakura, Mountnorris Bay; Unalla, Raffles Bay; (*p*) Woolna, east side of lower Adelaide; (*q*) Yaako or Terrutong (*yaako,* no), Croker Island and Raffles Bay; and Iyi (*iyi,* no), Popham Bay; (*r*) West Alligator River; (*s*) Allana, south-east of Daly Waters; (*t*) Caledon Bay.

Limbapyu (?)	immuta	lawidperra
West Alligator R.	minbara	gurat
Allana (?)	ganguji	kutjari
Bingonginga	yangalu	kutjera

There are no grammars; a few notes exist on Melville, Larrakia, Warrai, Ngolok-wanggar, and Kakadu. Gender in Kakadu extends to all natural objects, and numerals, pronouns and demonstratives change in agreement with the substantives they qualify: *jereini noorkudua* man one, *roulu noorkudua* stringy-bark-tree one, *ingordua wiorkudua* woman one, *peindi wiorkudua* stone one, *munedima* we men, *muniyembima* we women, etc. In Ngolok-wanggar a fourfold gender appears: *yinelli* a big man, *nunelli* a big woman, *wunelli* a big thing, *munelli* a big vegetable.

The pronouns show corresponding changes. The method of conjugating the verb varies, but all the languages appear to indicate person by a prefix, which changes for tense. Some verbal examples are:—Melville: *ngia a-beiya* I see; *inta ta-beiya* thou seest; *ngarra aura-beiya* he sees; *ngia ngu-puori* I go; *ngia ngira-puori* I went; Larrakia: *a-g'um* I say; *ne-g'um* thou sayest; *bi-g'um* he says; *bo-g'um* he said; *bara-g'um* he has said; *bin-g'um* he is talking; *nogolderk* (thou) run to me; *nogoldum* (thou) run from me; Kakadu: *ariy-eiring-ma* I dream; *meriy-eiring-mina* we two dream; *n-eiring-ma* thou dreamest; *n-eiring-mimina* you two dream; *d-eiring-ma* he dreams; *d-eiring-mimina* they two dream. The plural is formed by substituting *-mida* for *-mimina*.

5. *North-western Australia.* So far as they are known, the languages of north-western Australia fall into two groups. The first comprises the dialects about King Sound, and the second those in East Kimberley. The following are King Sound dialects:—(*a*) Sunday Island, Buccaneer Group; (*b*) Chowie, Ewenu Island; (*c*) Lower Fitzroy; (*d*) Napier Range.

The following are the East Kimberley dialects:—(*a*) Nowilnowillanna, lower Denham and Ord rivers; (*b*) Yamandil, Ord River; (*c*) Munmulla (Curramulla), west of the Ord River; (*d*) Walki (Chuanlinma or Kowrana), on Kimberley Goldfield, between the Margaret and the Ord; (*e*) Kisha, Hall's Creek, west of Munmulla.

	one	*two*	*ear*	*eye*	*hand*	*man*
Sunday Is.	aringk	kwir	nilimar	nimil	nemala	amba
Chowie	arinjie	kooyarra	neela-mur	nimmie	nemalla	umba
Lower Fitzroy	—	—	nilabubba	nemiljera	—	wamba
Napier Range	wingair	kujara	nilibib	nimilar	—	—
Nowilnowillanna	cherowi	panganyeri	yambirum	—	mallam	munamburri
Yamandil	—	—	karara	molu	—	—
Munmulla	cherowi	panganyeri	yardum	mula	mallam	munamburri
Walki	cherowi	kujara	yardum	molo	malla	munamburri
Kisha	nundi	buba	garding	mulji	murla	gerangen

The only grammar-note known concerns the Chowie language. In this the verb is conjugated by prefixes: *ngi nun-amoor* I throw; *jou min-amoor* thou throwest; *kinjing inn-amoor* he throws; *ngi arra nul-amoor* I throw not; *jou arra mil-amoor* thou throwest not; *kinjing arra ill-amoor* he throws not; *ngi nun-eep* I drink; *ngi kalla nun-eep* I drank; *ngi oong-eep* I will drink.

Linguistic Position of the Australian Languages. Many writers by arguments founded on defective material, and often by methods open to serious objection, have sought to establish a connection between the Australian languages, regarded as a single linguistic stock, and most of the other stocks. A brief résumé may be useful.

African. Bleek in 1872 somewhat doubtfully considered that there was a distant relationship between Australian and the Hottentot languages of South Africa, both being what he called 'sex-denoting languages.' In 1879 Hyde Clarke suggested a connection between the Yarra dialect of Victoria and the Bantu languages of Mozambique, and Curr in 1886 elaborated this theory to include languages of western Africa and the Sudan. The argument was based on the superficial resemblances of words; no reference is made to the radical difference which exists between African and Australian grammar, and Curr even disregards the difference between Bantu and Negro forms of speech.

Aryan. Some supposed miscellaneous affinities between Australian and Aryan languages were adduced by Brough Smyth and Taplin.

Andaman. Von Carolsfeld in 1890 suggested a relationship between the Andaman languages and Australian. He found some suffixes in both groups which were similar in form, though they differed entirely in meaning, and based his theory on these and on some resemblances in words. He paid no regard to the elaborate system of prefixes and infixes which forms the most important element of Andaman grammar, and is certainly absent in the southern languages of Australia. This theory was elaborated by Trombetti and Gatti in 1906.

Indonesian. North-western Australia is not far distant from the south-eastern part of the Malay Archipelago, where Indonesian languages come into contact with Papuan. Here there is a considerable mixture of vocabulary and grammar, unlike the ordinary Indonesian. Latham in 1844 affirmed a connection between the languages used on certain of these Malayo-

Papuan islands and the Australian. His view depended on imperfect vocabularies from Ombay, which were the only ones available; and his examples show only resemblances in a few words.

Dravidian. Norris in 1847 was the first to point out some resemblances between Australian and the Dravidian languages of southern India. These were approved by Bishop Caldwell in his *Comparative Grammar of the Dravidian Languages* (1875). They included a likeness in the agglutinate structure of the languages, the similarity of the pronouns, the use of post-fixes to nouns, the existence of two forms of the first personal pronoun in the plural number (one including and the other excluding the person or persons addressed), and the formation of verb-stems (inceptive, inchoative, causative and reflective) by additions to the verbal root. This theory was rejected by F. Müller, but partially adopted by Fraser and J. Mathew.

Munda or *Kolarian.* Professor Wilhelm Thomson of Copenhagen in 1892 tried to show a connection between the Munda languages of southern India and Australian, especially South Australian. His argument, based on vocabulary and grammar, was combated by Grierson in 1906.

Mixed. Two writers, Fraser and J. Mathew, ascribe a mixed origin to the Australian languages. The former adopts the Dravidian theory of Norris and Caldwell, but also finds a connection with other and diverse stocks, among which are the Munda, Papuan (undefined), Melanesian, Polynesian, Bantu, Aryan, Semitic and the so-called Turanian of northern Asia. The resemblances brought forward have no value. J. Mathew, assuming a threefold origin for the Australian languages, formulates a Papuo-Dravidian-Malay theory, without, however, accurately defining his terms. Papuan apparently includes Melanesian and various distinct Papuan stocks, and Malay excludes languages more primitive than itself. Mathew believed that the Tasmanians represented the primitive Australian stock, and that they were followed by Dravidians and, in a desultory manner, by Malays. At the same period, or later, Papuans or Melanesians mingled with Australians in the north and east of Queensland. Mathew's argument, like that of Fraser, is based entirely on the superficial resemblances of words; he does not affirm any grammatical identity of the various stocks. The argument fails because the resemblances between the words are often strained, and have no phonetic probability. The supposed likeness usually disappears when the words are analysed.

American. A comparison of Australian and American languages has been made by Dirr.

Among all these theories only two, the Dravidian and Papuan, have any claim to serious consideration. The likeness, however, between Dravidian and Australian is no proof of their genealogical connection, and it cannot be established that the two stocks are of common origin. The points of agreement noted by Caldwell were shown by F. Müller to be inconclusive. The grammatical features named are not possessed exclusively by the two groups, and the similar pronouns are found in languages totally different and spoken in far distant regions. There is also no general identity of grammatical particles in Australian and Dravidian, and no reliable correspondence in vocabulary. All that can be said with accuracy is, that the two groups—Dravidian and southern Australian—are of similar morphological type, i.e. agglutinate, with radical and functional changes of words expressed as a rule by suffixes.

On the other hand, many of the northern Australian languages resemble the Papuan (i.e. non-Melanesian) of New Guinea. They have the Papuan characteristic of diversity in vocabulary and grammar. Radical and functional changes of words are made not only by suffixes, but by prefixes and infixes. But, as the Papuan languages show no community of origin when one language is compared with another, it follows that the northern Australian languages cannot be expected to show any community with the Papuan of New Guinea, although one of them (the Saibai dialect of Mabuiag) is spoken almost within sight of New Guinea itself.

ABORIGINAL WORDS IN AUSTRALIAN-ENGLISH. Many aboriginal words have found their way into Australian literature, some locally, others generally throughout Australia. A few have been adopted in England. Morris estimates the number of these words at between 70 and 100. Some have been carried by the English from one district to another, and have been stigmatized as 'barbarisms,' because they were foreign to the particular district in which they were used.

The aboriginal words found in English are divided by Morris into three classes: (1) Aboriginal words which have been incorporated unchanged in the language, and which still denote the original object; (2) Aboriginal words similarly adopted, which have had their original meanings extended and applied to other things; (3) Anglicized corruptions of native words. To the first class belong a great many names of animals, plants, and objects and implements connected with the life of the natives. Some examples are:

Beasts: *kangaroo, wallaby*; *wombat*; *dingo*; *tuan, pongo* (flying-squirrel); *yarraman* (horse—not a wild horse); *jumbuck* (sheep).

Birds: *budgerigar, boobook, bulnbuln* (lyre-bird), *galah.*

Fishes: *nannygai, wobbegong, wollomai* (snapper).

Plants, fruits, etc.: *bangalay, boobyalla, bunya-bunya, karri, kurrajong, nardoo, pituri.*

Insects: *korrumburra* (blow-fly); *wichetty* (grub).

Persons: *koradji, boyla* (sorcerer).

Native Life: *mia-mia, gunyah, goondie, wurley* and *humpy* (all meaning 'hut' or 'shelter'); *boomerang, kiley*; *woomera, wommera* (throwing-stick); *leawil* or *leangle* (bent club); *nulla-nulla* (club); *mulga, hielaman* (shield); *coolaman* (water-vessel); *kurdaitcha* (shoe); *cooee* (a cry).

To the second class belong such words as *corroboree* (native dance); *bora* (initiation ceremony); *bunyip* (a fabulous monster); *gin, lubra* (woman; the latter is a Tasmanian word); *warrigal, myall* (a wild native); *billabong* (a blind effluent from a river); *mallee* (scrub); *bung* (dead).

Of the third class are such words as *paddy-melon* (a small wallaby); *pudding-ball* (a fish) *palberry* (native currant); *jarrah* (wood); *dilly-bag*; and possibly *barrack* (to jeer at).

Some words of apparently aboriginal origin are regarded as doubtful. Among these are *brumby* (wild horse); *waddy* (club, wood, fire-

wood); *jackeroo* or *jackaroo* (a 'new chum' working on a station); *yabber* (to speak).

One aboriginal word has enriched the vocabulary of chemical science. *Lerp*, a word meaning sweet, applied to a kind of manna secreted by an insect, has given its name to the chemical substance *Lerpamillum* derived from it.

BIBLIOGRAPHY. The earliest specimen of the aboriginal languages was obtained in 1770, during the stay of Captain Cook at the Endeavour River. It consists of a vocabulary of about 140 words, published in Parkinson's *Journal* in 1773. Shorter and slightly different lists were printed by Hawkesworth in 1773, and by Forster in 1778. These first records show the stability of the language; for King's vocabulary from the same place in 1827 and Phillips's in 1870 are easily recognizable as the Koko-yimidir language, used in the same neighbourhood in 1901. The accounts by Hunter in 1793 and Collins in 1798 of the first settlement at Botany Bay recorded words from the natives round Port Jackson; and these, with the vocabulary from the Endeavour River, were the only specimens of Australian languages known to Adelung when the *Mithridates* was published in 1806. Most of the early voyagers supplied short lists of words from various places. Flinders in 1814 and King in 1827 gave lists from the coastal tribes. Oxley in 1829 published the first inland dialect, from Limestone Creek. These were supplemented by Marsden in 1834.

The first *Australian Grammar*, that of the Hunter River dialect, was published by Threlkeld in 1834. It was followed by the Adelaide *Vocabulary* of Williams, those of Raffles Bay and south-western Australia by Wilson and Grey, and the collections of Eyre; also by the Adelaide grammar of Teichelmann and Schürmann in 1840, and those of Meyer for Encounter Bay, Schürmann for Port Lincoln, and Moorhouse for Murray River. In 1847, Hale, the philologist of the United States exploring expedition, published grammars of the Lake Macquarie and Wellington dialects, based on the work of the missionaries Threlkeld and Watson. Very little was published in the fifties, only Earl's vocabularies from the north and Salvado's *Memorië Storiche* being noteworthy; but interest revived from 1863 onward, and several short lists were published, with a collective vocabulary of 12 dialects, on the occasion of the Melbourne Exhibition in 1867, and a discussion of the languages by Müller in the Linguistics of the *Novara* expedition in the same year. The first Scripture translation (Narrinyeri) appeared in 1864, and the first edition of Ridley's *Kamilaroi* in 1866. Attempts were made in the seventies to preserve some of the fast-disappearing languages in the south and east; hence the collective works of Brough Smyth on Victoria, Woods on South Australia, Taplin on Narrinyeri, and Ridley (2nd edition) on Kamilroi. The following decade (1880-1890) was marked by the publication of many vocabularies—among them the great collection of Curr—but very few additions were made to a knowledge of the grammar. This deficiency was partly made up by the industry of R. H. Mathews from 1900 to 1908, and by the works of Fraser, J. Mathew, Roth, Kempe, and Tuckfield. Since 1900 a few grammatical works have been published, the chief being Roth's *Kokoyimidir*, Hey's *Ngerrikudi*, Planert's *Aranda* and *Dieri*, and the northern grammars in the *Report* of the Cambridge expedition.

A very large number of vocabularies have appeared in many periodicals, though their value is impaired in many cases by the adoption of erratic and unscientific modes of spelling.

The following works are of importance: Bunce, Daniel, *Language of the Aborigines of the Colony of Victoria* (2nd edn. 1859); Curr, E. M., *The Australian Race* (1886); Dawson, James, *Australian Aborigines* (1881); Forster, Dr. J. R., *Observations Made During a Voyage Round the World* (1778); Fraser, J., *Some Remarks on the Australian Languages* (1890); Gason, S., The *Manners and Customs of the Dieyerie Tribe* (1874); Grey, Sir G., *Vocabulary of the Dialects of South-Western Australia* (1840); Hale, H., *Ethnology of United States Exploring Expedition* (1844); Howitt, A. W., *The Native Tribes of South-East Australia* (1904); Mathew, J., *Eaglehawk and Crow* (1899) and *Two Representative Tribes of Queensland* (1910); Melbourne Exhibition Papers, *Vocabulary of the Dialects of the Australian Aborigines* (1867); Moore, G. F., *Descriptive Vocabulary of the Language in Common Use among the Aborigines of Western Australia* (1842); Morris, E. E., *Austral English* (1898); Parker, K. L., *Australian Legendary Tales* (1896, 1898) and *The Euahlayi Tribe* (1905); Ray, S. H., 'Linguistics,' in the *Report* of the Cambridge Anthropological Expedition to Torres Straits (1907); Ridley, W., *Kamilaroi, Dippil, and Turrubul* (1866) and *Kamilaroi and Other Australian Languages* (1875); Roth, W., *Ethnological Studies among the N.W. Central Queensland Aborigines* (1897) and *Kokoyimidir* (1901); Salvado, R., *Memorië Storiche dell' Australia* (1851), also Spanish (1853) and French (1854) translations; Schürmann, C. W., *Parnkalla* (1844); Smyth, R. B., *The Aborigines of Victoria* (1878); Spencer, W. B. and Gillen, F. J., *The Native Tribes of Central Australia* (1899), *The Northern Tribes of Central Australia* (1904), and *Native Tribes of the Northern Territory of Australia* (1914); Taplin, G., *The Narrinyeri* (1874) and *Folklore. . . . of the South Australian Aborigines* (1879); Teichelmann, G. G. and Schürmann, C. W., *Outlines of a Grammar . . . of the Aboriginal Language of South Australia* (1840); Threlkeld, L. E., *An Australian Grammar* (1834) and *The Native Tribes of South Australia* (1879), edited by J. D. Woods. See also numerous and valuable articles and notes by R. H. Mathews in various anthropological and geographical journals; and the diaries and journals of Flinders, P. P. King, Oxley, Eyre, Grey, Jukes, Parkinson and T. B. Wilson. S.H.R.

Aborigines. It is probable that, with the exception of one or two isolated groups in other parts of the world, the Australian aborigines represent the most archaic people extant and, in many respects, reveal the conditions under which the early ancestors of the human race existed. It must, however, be remembered that, from the point of view of savage life, conditions in Australia, during the time that it has been inhabited by human beings, have differed much from those in Europe, Asia, Africa, and America. In the first place, Australia has never been stocked with wild animals dangerous to human beings, nor with any apparently suitable for domestication. Even supposing there had been domesticable animals, it is quite possible that the aboriginal would have done nothing with them. He grinds many sorts of grass-seed to make into crude cakes; but it never occurs to him to sow the seed, and so insure a certain amount of food supply. In many tribes this

is to be associated with the fact that he knows nothing of the relation between the seed and the plant, and thinks that the latter grows because he makes it do so by means of magic. Secondly (and this is, perhaps, the more important reason) the Australian aboriginal, since his ancestors first inhabited the continent, has never had to contend with any higher race. He has developed along his own lines without the impetus given by competition with other peoples. In Europe early man had to contend with the bison, rhinoceros, tiger, lion, bear, and hyaena —a condition which must have sharpened his wits; in Australia he has had nothing more fearsome to meet than huge diprotodons and giant kangaroos, which were quite as anxious to get away from him as he was to capture and eat them. All that he has had to contend with have been men of his own or a lower level, and (at times and in certain parts) climatic conditions that trained him to habits of keen observation. There has been much speculation in regard to the origin of the present Australian race. In past times the whole of the continent (including Tasmania) was, presumably, occupied by one race. This original—probably ulotrichous—population was at an early period widely spread over Malaysia and Australia. Tasmania at that time was not cut off by Bass Strait, for the Tasmanians had no boats capable of crossing it, and must have gone over on land. Subsequently the land sank, leaving the higher parts above water in the form of King Island on the west, and the Kent, Furneaux and Flinders Islands on the east. A remnant of the old ulotrichous population was left stranded in Tasmania, where *Homo tasmanianus* survived until he came in contact with Europeans and was exterminated. There seems to be no doubt about this subsidence; what happened next is not so clear. *Homo tasmanianus* had the frizzly (ulotrichous) hair characteristic of negroid races. His weapons and implements were of the most primitive kind; no spear-thrower, no boomerang, only long, pointed, unbarbed spears, simple throwing-sticks, and the crudest form of unhafted, chipped stone axes, knives and scrapers. Of his organization, customs, and beliefs we know but little in detail. It is often (indeed usually) assumed that (1) at a later period an immigration of a higher race took place into Australia, and that (2) this race blended with the older inhabitants of the continent to produce the present Australian race. In regard to the first of these two assumptions every one is agreed, but in regard to the second there is room for grave doubt. It has been suggested that the two races are represented by the two primary moieties or phratries characteristic of Australian society, sometimes designated by names indicating a contrast of colour, such as 'eaglehawk' and 'crow.' The crow, black cockatoo, etc., would represent the Tasmanian element; the eaglehawk, white cockatoo, etc., the so-called Dravidian. It cannot, however, be said that the names—except in a few cases, and these representing only a small part of the continent—lend any serious support to the theory of the mixture of two races differing in colour. A certain amount of Malay intermixture in the north has also been suggested, but of this there is no evidence. In regard to language Sidney H. Ray says 'There is no evidence of an African, Andaman, Papuan or Malay connection with the Australian languages. There are reasons for regarding the Australian as in a similar morphological stage to the Dravidian, but there is no genealogical relationship proved.' They are pure nomads, the members of a tribe hunting over the land that has belonged to their ancestors, and not encroaching on that of others. They have favourite camping grounds, on which they build bark or brush *mia-mias*, or shelters, and where they stay as long as food and water supplies are abundant, moving on when these become scarce. During the day they are out in the scrub, the men hunting larger game, the women and children in search of smaller animals, grass-seed and yams. Attention has often been drawn to their great power of tracking, a faculty which they must cultivate if they are to live. Their evenings are spent in the performance of the ordinary dances, called corroborees; as a general rule, only men perform, while the rest of the camp makes the audience. Each corroboree has its own decorations and songs, and may occupy the evenings of two or three weeks. Apart from this ordinary camp life, there is, however—so far as the men are concerned—quite another side, which may be spoken of as the ceremonial. It is difficult to say how much time is occupied by this, but in many tribes weeks or even months are spent yearly in attendance upon, or taking part in, ceremonies of a sacred nature that only initiated men may witness; and the older a man becomes the more time he spends in this way.

Finally it must be remembered that, owing to the vast area over which the tribes are scattered and the very different conditions under which they live—some exposed to the often fierce heat and droughts of the interior, others living amongst shady forests in the south-eastern ranges, and others again in the far north camped by the side of rivers and pools where there is a constant and plentiful food supply—there are necessarily great variations in customs, organization, and beliefs. The different tribes may be regarded as descended from ancestors who all observed certain customs and were regulated by a common social organization. In course of time, as they wandered over the continent and became divided into isolated groups, they developed along different lines; yet in essential features the resemblance of their customs, beliefs and organization is remarkable.

W.B.S.

Origin. It is now fairly certain that man's nearest living relatives are the anthropoid apes—the gorilla, orang, gibbon, and chimpanzee. He possesses in common with the gorilla and the chimpanzee about three hundred structural features that are not found in any of the lower monkeys. Turner has pointed out that the simian features are not all concentrated in any single race, but it is allowed that the Australian aborigines exhibit the largest number of apelike characters, and belong to one of the most primitive (in the sense of oldest) races of mankind. It is supposed that Neanderthal man and men of his type, who have long been extinct, lived for many thousand years contemporaneously with a *Homo* of another type, and that from this other type the modern races have sprung. One notable character of Neanderthal man—in fact, the feature most obvious to ordinary observation—was the forehead with its large glabella and prominent superciliary ridges; and it was once thought that this showed an affinity, if not a racial connection, between that type and the aboriginal such as existed in no other modern race. But this character has been found in individuals of the most modern type—Sir

William Turner found it in the skull of an Aberdeenshire Scot; and evidence from embryology and genetics has shown that in the aboriginal this peculiarity is almost certainly a late development. Other considerations, too, have led recent anthropologists to regard the aboriginal as part of the bundle of present-day races, having no more radical or racial connection with the Neanderthal type than any of the others.

In anthropology the term 'race,' used strictly, is applied to one of the larger divisions of mankind whose members have certain physical characters in common. The most important features in the classification of races are the characters of the hair and the form of the head, which are remarkably constant in the chief divisions of mankind. These divisions may be called 'White,' 'Black,' and 'Yellow.' In which of them is the aboriginal to be included?

First it is to be noted that some writers class the Australian aborigines as a distinct race, equipollent to the three others, on account of their numerous and remarkable characteristics. In order to account for apparent 'varieties,' local or sporadic, two types have been assumed —a black type, which differs, however, from all negroid races in the character of the hair, and a Caucasian melanochroic type. Several modifications of this hypothesis have been suggested; but Professor Sir Arthur Keith gives us a new view-point when he says: 'Of all the races of mankind now alive, the aboriginal race of Australia is the only one which, in my opinion, could serve as a common ancestor for all modern races. The common ancestor has to yield descendants which, on the one hand, might become the typical inhabitant of central Africa, and, on the other, the fair-haired native of north-western Europe. The Australian native has those intermediate and generalized characters needed for such an ancestral form.'

If the Australian aboriginal is the nearest to the original stock, what are his affinities? Formerly he was classed with the negro, because both possessed a flat nose, protruding lips, projecting jaws, and large-sized teeth. But this is just as if one should class the echidna and the porcupine in the same order on account of the similarity of their spines, totally disregarding their broad and fundamental structural distinctions. The characters mentioned are very variable, not only in the Australian aborigines and in the negroes but in all races, and are just those characters that change very rapidly in individuals and in the race on account of changes in environment and habits. Further, they are the characters that would become specially developed and fixed in apes and in the lower human races on account of similarity of food, habits, and surroundings.

With respect to the brain Professor Elliot Smith has been able to do a great deal towards establishing which anatomical characters should be considered primitive, which should be accepted as evidence of specialization, and what value should be attached to the various features of the brain as an indication of specialization and racial affinities. By applying the criteria he has established to Australian aboriginals' brains, Dr. J. F. Flashman was able to say (with a fair amount of certainty considering the all-too-limited material at his disposal) that, on the important points that count, the aboriginal shows undoubted primitive racial features. Other parts of the body also furnish evidence; for example, the molars and wisdom teeth in the aboriginal's upper jaw develop in a manner quite different from that noted in 'white' men, but similar to that seen in certain lower animals. Researches on this subject have not as yet been extensive enough to enable one to say what other races, if any, exhibit a process of dental development similar to that of the aboriginal; but this form of development sometimes occurs in white individuals, and may on occasion give rise to one form of the condition known as 'impaction of the wisdom.'

Again, it was believed until recently that the shin-bone in the Moriori (the original inhabitants of New Zealand, whose last members survived in the Chatham Islands) showed a nearer approach to the sabre shape in its upper part than occurs in any other race; in other words, its platycnemic index was the lowest. Now, however, it has been found that the Australian aboriginal shows indices very much lower than those of the Moriori. In this respect, then, these two races are brought into close affinity. The same condition is found in the shin-bones of prehistoric man, and in all the anthropoid apes except the orang. A condition associated with this—retroversion of the head of the shin-bone, which is very marked in the aboriginal—also occurs in prehistoric man and in the human embryo in all races, but disappears early in Caucasian children, persisting, however, in some of the lower races.

It is accepted as almost indisputable that the Australian race is not autochthonous, but that it migrated from some distant centre to its present habitat. While this view is possible, the subject demands re-examination in the light of Professor Alfred Wegener's recent studies. Many hypotheses have been formulated regarding its previous habitat. Topinard and others concluded that Australia was originally inhabited by a race of the Tasmanian type, which disappeared before a taller race that came from parts unknown. Flower and Lydekker (1891) thought the Australians were a cross between two already-formed stocks. Keene still considers that they are a blend of two, or at the most three, different elements in extremely remote times. Huxley held that they were a homogeneous group. Finsch (1884) from extensive observations concluded that they were all of one race. Alfred Russel Wallace (1893) pointed out the aboriginal's resemblance to certain Asiatic races—the Veddahs, Todas, and Ainus—and concluded that he was really a low Caucasian type.

Dr. Semon (1899) in his work *In the Australian Bush*, adopts and defends the theory that the Australians and the Dravidians (primitive inhabitants of India) have sprung from a common branch of the human race, and that the Caucasians have undoubtedly sprung from the Dravidians. This makes the Australian aboriginal more nearly allied to us than the comparatively civilized Malays, Mongols, or Negroes; according to this view, indeed, the Australian aboriginal would be racially the uncle of the Caucasian. According to another view, by which the Veddahs as a primitive type gave origin to the Dravidians and the Australian aborigines, the two latter would be brothers. Lydekker (1898) abandoned the two-race theory, and reached independently the same conclusion as Wallace. Most anthropologists now accept the one-race theory. Professor Gregory in *The Dead Heart of Australia* accepts this view and abandons his former position.

Some writers give the Australian even greater importance. Stratz has taken him as a central unit, a prototype, around which he groups all the rest of the races of men; Schoetensack holds that all races of men were evolved in the Australian continent. The unity of the race may be accepted as established. The latest word on the subject is Sir William Turner's (1908); 'The balance of opinion is indeed in favour of the view that throughout Australia the present natives generally conform to one pattern in features, colour, and mental character; though possibly on the coast, local infusion of Papuan, Polynesian or Malay blood may from time to time have been introduced amongst them. Indeed, as Giglioli has suggested, the idea of an existing woolly-haired race in Australia is probably due to the loose way in which the terms woolly and crisp have been used by explorers who were not anthropologists.'

It may therefore be taken as established that the aborigines are a homogeneous race, unmixed in descent, of Caucasian stock, not negro or negrito, but differing from every race in geographical propinquity to them in their physical characters and language, and in the absence of pottery, agriculture, sea-craft, bows and arrows, and architecture—a primitive race, a relic of the oldest human stock. Yet we must not draw too wide an inference from mere casual examination, and we must be prepared to find a large amount of well-marked variation. The examination of a number of aboriginals will show facial resemblances to all the known recognized human types, Ethiopian, Mongolian, Caucasian, American. In this respect there is an analogy between the Australian aboriginal and the Australian fauna. The primitive marsupials, distinguished by certain features—such as epipubic bones, inflected angle of the lower jaw, aplacentation, double uterus, etc.—were cut off at an early period from competition with nearly all other classes of mammals. The requisites for individual and racial life are food and safety; and since, among mammalian forms, the kinds of food are limited, and the means of overtaking, seizing and disposing of it are also limited, the limbs, teeth, and intestines become specialized along similar lines in animals living on similar diet (e.g. carnivora, graminivora, insectivora) according to the circumstances of the localities in which they have been evolved. Such convergence in evolution is illustrated in an extreme degree, for example, in the bodily outlines of the piscine shark and the mammalian whale. Not only so, but racial characteristics which have been looked upon as fixed in a people, may become very much changed within a comparatively short time by changes of food and environment.

As to the physical and mental differences found in tribes in various parts of the continent—say in the Alligator River district and in certain parts of central Australia—it was pointed out long before Darwin's day that food and climate and mental degradation will, within a comparatively short time, cause enormous variations in the people. Analogous changes may be seen in Americans who tend to a Red Indian type of face, neck, and vocal organs, and also in Europeans who have migrated to Australia and in their descendants.

In 1839 Dr. Charles Pickering visited Australia as a member of the United States Exploring Expedition commanded by Wilkes. He records that an hour after landing at Sydney he met an aboriginal in the street, wearing European costume, whom he instantly recognized; and this single example seemed to dispel all danger of subsequently confounding the Australian with any other race of men. He subsequently saw two or three dozen aboriginals in the settled parts, and thus described them: 'Some individuals were of surpassing ugliness; while others, contrary to all anticipation, had the face decidedly fine; and several of the young women had a very pleasing expression of countenance . . . . Strange as it may appear, I would refer to an Australian as the finest model of the human proportions I have ever met with; in muscular development combining perfect symmetry, activity, and strength; while his head might have compared with the antique bust of a philosopher.' W.R.S.

Distribution. Wegener, from investigations regarding the distribution of the ancient rocky crust of the earth, the structure and position of the great continental mountain ranges, the correspondence between the contours of the continents on opposite sides of the Atlantic, bathymetric surveys of the oceans, palaeontological researches in the continents, the geographical distribution of animals, and astronomical data, infers that Australia up to the beginning of Jurassic times was connected in the west with India and Ceylon, and through them with Madagascar and South Africa; and after breaking away from India it was still, perhaps as late as Eocene times, connected through Antarctica with South America. Two other recent lines of investigation must be correlated with Wegener's theory. One concerns the question How long has man, as man, existed on the earth; the other concerns the region where we are to look for his lineal progenitors. Such a correlation would appear to furnish materials for a theory that man originated somewhere in, and spread from, an extensive land-mass consisting of a southern continent continuous with Africa, southern Asia and Australia; that his origin dates back many hundreds of thousands of years; that the ape families were his collaterals, not his progenitors; and that the Australian aboriginal is probably, amongst surviving peoples, nearest to the primary stock and not impossibly the source from which many, if not all, of the other peoples originated. There is perhaps more scientific foundation for this theory than for many that have been advocated.

The puzzling problems of migration would be much simplified if the proof of Wegener's theory were complete, and if further evidence bore out recent statements regarding the age and origin of man and the place of the Australian aboriginal among mankind. But it may be well to set forth some of the theories regarding the peopling of the Australian continent that were put forth before the question above referred to was considered or propounded.

It is generally supposed that the Australian continent became peopled from a centre in the north or north-west by tribes that dispersed or migrated in certain definite directions. These lines of migration are defined according to the occurrence along them of tribes possessing similar physical characters, dialects, traditions and customs. The fact that adjacent tribes often show considerable differences in these respects is explained by supposing that they arrived at these particular places at different times and by different routes, having acquired variations in the process of migration.

FISH TRAPS ON DARLING RIVER, CONSTRUCTED BY ABORIGINES

With the limited knowledge of dialects, weapons, habits, customs and traditions of the various tribes at his disposal, Eyre hazarded the opinion that

> Australia was first peopled on its north-western coast, between the parallels of 12° and 16° S. latitude. From whence we might surmise that three grand divisions had branched out from the parent tribe, and that from the offsets of these the whole continent had been overspread. The first division appears to have proceeded round the north-western, western, and south-western coast, as far as the commencement of the Great Australian Bight. The second, or central one, appears to have crossed the continent inland, to the southern coast, striking it about the parallel of 134° E. longitude. The third division seems to have followed along the bottom of the Gulf of Carpentaria to its most south-easterly bight, and then to have turned off by the first practicable line in a direction towards Fort Bourke, upon the Darling. From these three divisions various offsets and ramifications would have been made from time to time as they advanced, so as to overspread and people by degrees the whole country round their respective lines of march. Each offset appearing to retain fewer or more of the original habits, customs, &c. of the parent tribe in proportion to the distance traversed, or its isolated position, with regard to communication with the tribes occupying the main line of route of its original division; modified also, perhaps, in some degree, by the local circumstances of the country through which it may have spread. (Eyre's *Journals*, ii.405.)

Eyre also expressed his confidence that the precise original divisions and the routes of distribution might be determined when more particulars were collected regarding the various tribes; it is to be feared, however, that there is less hope now of doing this than there was in his time. Further study by Howitt, Spencer, and Gillen would lead to the conclusion that there were three main lines of distribution, corresponding roughly to those laid down by Eyre. The chief evidence is founded on the occurrence in the various tribes of similarities in grammar and dialects, the practices of circumcision, sub-incision and knocking out certain front teeth, and other observances.

How long have the aborigines been here? As yet no fossil remains yield such trustworthy evidence as would enable one to make a likely guess; there is no Stonehenge or Great Pyramid from which one could theorize astronomically on the subject of their possible presence. Some facts point to long residence on the continent. One of these is the differentiation in language. Eyre says that the variations of dialect are frequently so great that a person thoroughly acquainted with one dialect has not the slightest clue to what is said by a tribe speaking a different one. Eyre and others note that many aboriginals cannot give any interpretation of the dance songs in their own districts. This would seem to point to a common origin of their plays and dances.

It is obviously impossible at the present time to form any accurate estimate of the numbers of aborigines in various parts of the continent towards the end of the eighteenth century. Not until men like Grey, Eyre, Threlkeld, Teichelmann, M'Combie, Meyer, Schürmann, Taplin, Wyatt, and Gason began to write and record, do we find materials available for estimating the number existing over half a century ago; and what impresses one in the writings of all these observers is the extreme difficulty they encounter in arriving at even an approximation of the number of the aborigines. Eyre despairs of forming any opinion, even approximating the truth, of the aggregate population of the continent, or the average number of persons to be found in any given space. A district, he says, that may at one time be thinly inhabited, or even altogether untenanted, may at another be teeming with population. The wanderer may at one time be surrounded by hundreds of savages, and at another, in the same place, may pass on alone and unheeded. Grey says he has found the number of inhabitants to a square mile to vary so much from district to district, from season to season, and to depend upon so great a variety of local circumstances, that he is unable to give any computation which would even nearly approach the truth. Modern writers, however, show remarkable unanimity in recording the aboriginal population at 150,000 at the time of the settlement of Europeans. If there were any means of proving or disproving the correctness of the estimate something critical might be said regarding it. All that can be said is that it is a guess.

As for the extreme variations noted by Eyre and Grey, we should note that, according to Woodruff, in the eolithic or protolithic stage perhaps all Europe contained but a few thousand men, widely scattered in tiny groups; even in the next (neolithic) stage but few existed, and in the bronze age there were no dense masses: the Veddahs of Ceylon, one of the lowest types at present, scarcely number 2000 though inhabiting vast areas. Current ideas as to the density of population in ancient civilized times are usually very erroneous. When our ancestors in Denmark were in a stage of culture corresponding to that of the Australian aborigines, only 500 could live in the 15,000 square miles of that country. When one considers the vast differences in range and characters of climate and environment between Europe and Australia, one sees the necessity for caution. The conditions affecting existence and evolution may have been very different in Australia from those that have obtained anywhere else in the world.

When we inquire into the numbers in districts occupied by Europeans at the time when observations were attempted, we find that observers had great difficulty in forming conclusions. In South Australia (not including the Northern Territory) Moorhouse concluded that in 1843 there were about 1600 aborigines in regular or irregular contact with the Europeans distributed in the Adelaide district, Encounter Bay, Moorundie, Port Lincoln, and Hutt River. If the districts within 120 miles S., 160 miles N., and 200 miles E. of Adelaide were included, he estimated that the total would be about 3000. Eyre thought there must be about twice as many. J. D. Woods, on the basis of Eyre's estimate, calculated that there might be about 12,000 in all in South Australia. In the districts to which Moorhouse referred few now survive. With the exception, perhaps, of a solitary member, the Gawler, Adelaide and Port Adelaide tribes are extinct. Not one individual survives in the Kapunda, Burra, or Rufus districts. In 1840 the Narrinyeri tribe numbered about 3000; in 1877 it had dwindled to 613; in 1909 only two individuals survived. The hundreds or thousands of blacks in the Murray district 80 years ago are represented to-day by a score or so at the Point Macleay mission station on Lake Alexandrina. M'Combie says that Victoria, when first colonized, contained as many as 7000 aboriginals, but that in 1858 the number had dwindled to 300. The latest (census of April 1921) official estimate for that State is

With the limited knowledge of dialects, weapons, habits, customs and traditions of the various tribes at his disposal, Eyre hazarded the opinion that

> Australia was first peopled on its north-western coast, between the parallels of 12° and 16° S. latitude. In 1840 the Narrinyeri tribe numbered about 3000; in 1877 it had dwindled to 613; in 1909 only two individuals survived. The hundreds or thousands of blacks in the Murray district 80 years ago are represented to-day by a score or so at the Point Macleay mission station on Lake Alexandrina. M'Combie says that Victoria, when first colonized, contained as many as 7000 aboriginals, but that in 1858 the number had dwindled to 300. The latest (census of April 1921) official estimate for that State is

111. For the other States the numbers are:—New South Wales, 1501; Queensland, 12,614; South Australia, 1609; Western Australia, 25,587; the Northern Territory, 17,349—a total of 58,771, rather more than 54 per cent being males. This is probably the most accurate estimate yet made in connection with any census.

W.R.S.

Physical Characteristics. The Australian is a primitive race. This established and accepted fact, taken in conjunction with the superficial observations of early explorers, the misrepresentations of some of the early settlers, and the inaccurate reports of later writers, has given rise to an impression that it is also a degraded race. But primitiveness and degradation are not synonymous. Hand-reaping by hook or sickle is a primitive method of harvesting compared with the self-binder or the stripper, but it is not on that account degrading. The Australian race is not degraded, physically, mentally, or morally. Some individuals and some tribes may exhibit inferior and degraded traits, but the race as a whole shows no signs of retrogression or degeneration.

The average height of the aboriginal is little, if anything, less than of the Englishman. Very tall individuals, over six feet, are not uncommon, and may occur anywhere. At 21 years of age, David Lindsay's boy, Dick Moogee, from central Australia, was 6 feet 6 inches high. Brough Smyth records an adult male as measuring only 5 feet 1 inch. Measurements vary greatly with locality. Women are usually about from five to six inches shorter than men. The upper part of the body is usually better developed than the lower. The legs and arms are longer, relatively to the trunk, than those of Europeans. It is noteworthy that this feature appears in certain ancient Grecian works of art which have been regarded as of the greatest beauty, and that this perfection of elegance seems to depend on the apparent abnormality—that what was for long regarded as 'so unaccountably excellent in its general appearance, hath been owing to what hath seemed a blemish in a part of it.' In many aboriginals the legs lack girth (especially in the calves), but many show excellent proportions, and are well-built and muscular. The wrists and hands are finely formed. The hands are distinctly small, and remarkably narrow. Brough Smyth says, 'It would be impossible to find in a tribe of Australians such hands as are seen amongst the working classes in Europe. An English ploughman might perhaps insert two of his fingers in the hole of an Australian's shield, but he could do no more.' The lunule of the finger-nail is as well marked in the Australian as in the European. The men have deep and broad chests. They may remain lithe, active and supple to a very great age; the women, as a rule, 'go off' in condition early, probably on account of the hard work and privation to which they are subjected.

The skull of the aboriginal is long, the sides are nearly vertical, and the vault is strongly rafter-like or roof-shaped. The forehead is low and flat. Its lower part (the glabella and superciliary ridges) is strongly marked. The hair is long and straight, wavy or curly, never woolly like the negro's, and not frizzly except from manipulation It is generally worn short by both sexes, and is usually abundant and of a silken, glossy appearance. The practice of depilation is common, the hair on different parts of the body being removed for various reasons. This practice is sometimes connected with initiation ceremonies. In colour the hair is very dark brown, or black; its shaft, in section, is oval and relatively thick, though one meets with many specimens of fine silky hair. In some women the hair is as black and lanky as among Mongolians. Beards and moustaches are common; even women sometimes grow strong grey beards and moustaches. The hair turns grey on all parts. Baldness is almost unknown; when it occurs, it appears to begin at the forehead and to extend backwards. The skin is usually velvety in smoothness and is chocolate-brown, or of a dark copper colour; it varies much in its depth of tint, largely in accord with the amount of exposure to which it has been subjected. When thoroughly clean it may show marked iridescence. The sooty tinge of the African negro is said not to occur. The skin of the newly-born child is of a light reddish or honey colour, but in two or three weeks becomes dark. The bodies of children are often covered by long, soft, downy hair, especially along the spine; their skin shows the same varieties of tint as that of older people. The aspect of the face varies greatly in tribes and in individuals. The eyes are sometimes said to be far apart, sometimes to be near, but examination shows that in this respect they resemble those of the European. They are deeply set, and of a dark brown or reddish-hazel colour, soft and intelligent, with black eyelashes. The pupils are large and dark, and the 'whites' are yellowish. The blackfellow is said to have much keener vision than the European; but vision, like some other senses, is so much a matter of inference and cultivation that the statement requires qualification. The deep notch at the root of the nose and the overhanging brows are very characteristic. These characters are very quickly 'bred out' in crossing with the white, and the same is true also of the dark colour of the skin. As in the case of the Maoris, the progeny of half-castes with half-castes or whites is nearly white; but instances in which some or all in a family may revert to the black show that the heredity of these half-castes requires investigation. The nose is very flat and very wide. The excessive width of nose and the openness of the nostrils is usually ascribed to the custom of wearing a 'nose stick,' but it is well-marked in young children. A Jewish cast of countenance, possibly more apparent than real, is frequently and widely met with. The mouth is wide; the lips are rather thick, but not swollen like those of the negro's; and the jaws are usually somewhat projecting. The teeth are large, well-formed, regular; in the uncivilized individual they may be evenly worn from excessive use, but are never decayed. Irregularities are almost invariably due to crowding in the front part of the jaws. The grinders are of large size; the wisdoms may be as large as, or larger than, the first and second molars—a very characteristic feature. The upper jaw in the vast majority does not overhang the lower, but bites flush against it. The cheek-bones are often high, and the chin receding. The neck is short and thick. The ankles are small. The heel resembles that of the European. The forepart of the foot is usually very broad and thick, the great toe is 'loose,' and a native can as readily pick things up with his foot as he can with his hand. The carriage of the aboriginal is graceful, with the trunk erect, the head thrown back and the knee lifted forwards in a peculiar

fashion rarely seen in any other race. One can hardly be said to have seen human grace of carriage who has not seen an aboriginal walk. In sitting on the ground, which is his usual custom, the blackfellow crosses his legs and brings his heels nearly under him; a woman usually sits almost on her knees with one foot right in the crutch. These positions, like the difference in the 'fighting fist' of whites, seem to be sexual distinctions. The men in standing often place one foot against the opposite knee and help to balance themselves with a wommera or some other weapon or implement. Even the young children naturally assume this figure-of-four pose.

At one time it was supposed that the aboriginal exhibited few, if any, bodily abnormalities. Extensive observations, however, have shown that the anatomical abnormalities and variations found among aborigines are probably much more numerous than in any other known race, ancient or modern.

The body exhales an odour quite characteristic of the race, noticeable by whites, horses, cattle, and dogs, just as the odour of the white man, which is imperceptible to himself, is noticeable by the black man. Perhaps the Japanese is the only race that is odourless in this sense. The voice is soft and musical, and rich in inflections. The traditional geisha-singing in Japan, which has come down for hundreds of years through artists and trainers, and which strangers rarely witness, is a marvellous combination of bodily pose and musical expression, and yet an embodiment of ease and repose; the voice inflections are different from anything heard elsewhere in music—the nearest approach to them that I know is the pleading, coaxing, wheedling, whining tones of an Australian gin begging tobacco.

Mentally the aboriginal in his native surroundings is observant, self-reliant and quick. Under civilization, however, he appears to lack stability, probably because he faces uncongenial conditions in a new environment. Children in school can be educated like white children, and to the same extent, and the aboriginal parents object to any distinction in the curriculum or the standard required. It is usually said that they never progress beyond a certain stage, and that in arithmetic particularly they are deficient, being unable to count above two or, at the most, four. There is no evidence for such assertions. In some uncivilized tribes there are numerical names for children up to the number of ten. A blackfellow, born of uncivilized parents and brought up among whites, or mixing a great deal with them, will tell the distance between two places thus: A to B, 10 miles; B to C, 6; C to D, 14; D to E, 8; E to F, 5; and say the total, 43, without a halt. The ordinary blackfellow is as good at figures as his white brother. Some speak English chastely and beautifully. Some train themselves in music, and can play classical choruses and similar pieces on the organ with great skill and expression. Some show great mechanical ingenuity, and read and understand books on mechanics and physics. Women learn all sorts of domestic work, and can read and write as well as their white sisters in similar circumstances.

As a race the aborigines are polite, proper in their behaviour, modest, unassuming, gay, fond of jokes and laughter, and skilful mimics. Even in rough horse-play they seldom lose their temper. Some possess a fund of humour. They are by nature frank, open and confiding, of a lively disposition, and cheerful under all sorts of privation; sometimes they show great delicacy of feeling. In many things the aboriginal is scrupulously honest; and his morality, according to his lights and teaching, is as high as among the generality of uneducated white people. Inter-tribal etiquette is punctilious, and breaches of it lead to fighting. Many aboriginals show great courage.

W.R.S.

Organization. Though Ridley and others did valuable pioneer work, the first serious attempt to study Australian tribal organization in detail was made by Fison and Howitt, whose *Kamilaroi and Kurnai* may be regarded as having laid the foundation of our knowledge of Australian anthropology. In this they demonstrated the existence of (1) two primary exogamous moieties, (2) classes into which the moieties were divided, and (3) totemic groups. In the case of the Kamilroi, the organization of a typical Australian tribe was adequately set forth for the first time, and it was shown that the so-called 'terms of relationship' were, fundamentally, group and not individual terms.

As might be expected, organization varies greatly in tribes inhabiting different parts of the continent. Speaking generally, it may be said that every tribe is divided into two moieties; this is the fundamental feature. Each of these is usually divided into two classes, and these may be further divided into sub-classes, so that in the most highly developed normal tribes we have two moieties with four sub-classes in each; further, different names are applied to the corresponding male and female sub-classes. This organization governs kinship; and as, with its associated terms of relationship, it refers to the whole tribe and to every member of the tribe, so each individual has a kinship or relationship term that he applies to every member of his own tribe—and to members of other tribes if they happen to visit his camp or if he goes to theirs, as may often happen during the performance of important ceremonies. In some (but very few) cases there are terms applied to single individuals; these, however, are rarely met with, and it is only by realizing the fact that the group, and not the individual, lies at the basis of tribal organization that this organization, as well as their habits, customs, and beliefs, can be understood. For example, in the Pitta Pitta tribe (Queensland) a woman calls her actual mother 'umma,' but applies the same name to each member of the group of women any of whom her father might lawfully have married; a man calls his actual wife or wives 'nopa,' but applies the same term to each member of the group any of whom he might lawfully have married; and so on right through the whole series of terms. Further, the group relationship shows out strongly during the performance of all their ceremonies, and even in camp life. There are, for example, men of a certain group who may lawfully marry women of another group. If the father of one of his eligible wives dies, though the man may never have seen father or daughter, it is still his duty to cut himself in the same way as if his actual wife's father had died. So again, if he catches a wallaby, should there be any man in camp whose daughter he might lawfully marry, he must give food to that man even if he has no daughter. The affairs of any individual are, at bottom, mainly concerned with the group of which he is a member; the family enters to a slight, but only a very slight, extent. During the very large, and by far the most important, part of his life when he is associated with his fellow

tribesmen (and often tribeswomen also) in the performance of the multifarious ceremonies that occupy so much of his time and thought, the group is predominant, the family is unrecognized.

The following examples are representative of the main features in regard to tribal organization—though of course only salient points are noted. Taking Australian tribes as a whole, we may divide them into five groups:—

(1) Those with two moieties and no class names. In all of these descent is counted in the maternal line.

(2) Those in which each moiety is divided into two classes and in which descent is counted in the indirect maternal line.

(3) Those in which each moiety is divided into two classes or four sub-classes, and in which descent is counted in the indirect paternal line.

(4) Those in which each moiety is divided into two classes, and in which descent is counted in the direct paternal line.

(5) Tribes that may be regarded as abnormal, inhabiting coastal areas in certain parts (such as Victoria and the Northern Territory) in which, if any class organization were ever present, it has been modified or superseded by some form of local organization.

(1) *Tribes with two moieties, but no classes.* These are chiefly met with in the interior of the continent and probably represent the most primitive form of organization; but, though there are no class names, there are groups of individuals standing in definite relationships to one another, who correspond to the groups of individuals to whom class and sub-class names are given in other tribes. In some cases the moiety names are Kararu and Matteri, in others Mukwara and Kilpara, in others Kumite and Kroki, or variants of these. Of these tribes the Dieri is an example. A Kararu man marries a Matteri woman and their children are Matteri: a Matteri man marries a Kararu woman and their children are Kararu.

(2) *Tribes in which the moieties are divided into two classes, and descent is counted in the indirect maternal line.* These can be illustrated by two examples. (a) the organization of the Pitta Pitta, which is typical of that of many central Queensland tribes, may be represented thus:—

1	2	3	4
Utaru.	Pakuta.	Children.	Children.
Kupuru Wungko	Kurkilla Bunburi	Bunburi Kurkilla	Wungko Kupuru

The two moieties are Utaru and Pakuta, each of which has two classes. The system as shown in this and all following tables is, that men of column 1 marry women of column 2, and their children are shown in column 3. Men of column 2 marry women of column 1, and their children are as shown in column 4. It will be seen that a woman's children belong to her moiety, but not to her class; in other words, we have direct maternal descent of the moiety and indirect of the class. (*b*) The organization of the Kamilroi, which represents that of many tribes in the interior of New South Wales and Queensland, agrees fundamentally with the Pitta Pitta, but has distinct names for males and females, thus:—

1	2	3	4
Kupathin.	Dilbi.	Children.	Children.
Ipai (Ipatha) Kumbo (Butha)	Kubi (Kubitha) Murri (Matha)	Murri (Matha) Kubi (Kubitha)	Kumbo (Butha) Ipai (Ipatha)

Descent is counted in the indirect female line, so far as the class is concerned; but, in addition to the ordinary marriage, it is permissible for a man to marry a woman belonging to the same moiety as himself, but to another totemic group. So far as the class name is concerned, the children take the one they would have taken had their mother married the correct man. It may be noted that in all tribes, when an irregular marriage is permitted, the children take the class appropriate to the normal marriage of the woman.

(3) *Tribes in which the moieties are divided into two classes or four sub-classes, and in which descent is counted in the indirect paternal line.* These tribes occupy a very large area in the centre and northern parts of the continent, and extend right across into Western Australia; at all events, they stretch beyond the far western end of the Macdonnell Ranges, and are met with again on the western coast. The Arunta, Karriara, and Warramunga may be taken as types. The Arunta organization in the southern part of the tribe is thus:—

1	2	3	4
Moiety 1.	Moiety 2.	Children.	Children.
Panunga Bulthara	Purula Kumara	Bulthara Panunga	Kumara Purula

In the southern part of the tribe there are only four class names; but as a matter of fact each of these is divided into two groups. The Panunga and Purula, two intermarrying groups, can be arranged as follows, using the letters *a* and *b* to indicate the two groups:—

Panunga *a* marries Purula *a*, children are Bulthara *b*.

Panunga *b* marries Purula *b*, children are Bulthara *a*.

A Panunga *a* man calls Purula *a* women *Unawa*, Panunga *b* men *Ipmunna*, and Purula *b* women *Unkulla*. The Unawa women are eligible as wives; under normal conditions the Unkulla are not. In the northern part of the tribe distinct names are given to the groups, which now form what are called eight sub-classes; as said before, these are always functionally present. The names and marriage arrangements are as follows:—Uknaria is the equivalent of Panunga *b*, Appungerta of Bulthara *b*, Ungalla of Purula *b* and Umbitchana of Kumara *b*.

1	2	3	4
Moiety 1.	Moiety 2.	Children.	Children.
Panunga Uknaria Bulthara Appungerta	Purula Ungalla Kumara Umbitchana	Appungerta Bulthara Uknaria Panunga	Kumara Umbitchana Purula Ungalla

The organization of the Kaitish, Warramunga, and other tribes in the northern central area, as far as the Katherine River in the north, and eastwards towards the Gulf of Carpentaria, is fundamentally the same, with different names for sub-classes and, in many, distinct names for the corresponding women's sub-classes, giving thus sixteen sub-class names in all. This feature exists also in the East Kimberley tribes in Western Australia. For example, among the Warramunga the equivalent of the Uknaria men are called Tjunguri, and the women of the same group Namigilli. In some tribes also the moiety names are retained.

Among the Warramunga the equivalent of moiety 1 in the Arunta is called Uluuru, and that of moiety 2 Kingilli. In the Karriara tribe in Western Australia the moiety names are lost, four classes are present, and the marriage arrangements are as follows:—

1	2	3	4
Moiety 1.	Moiety 2.	Children.	Children.
Banaka Paljari	Boorong Kalmera	Paljari Banaka	Kalmera Boorong

It will be seen that, except for the class names, the arrangement is identical with that of the southern Arunta; and a similar organization is evidently widely spread in Western Australia.

(4) *Tribes in which each moiety is divided into two classes, and in which descent is counted in the direct paternal line, so far as the class name is concerned.* The Mara tribe, inhabiting country on the Gulf of Carpentaria between the Roper and Macarthur Rivers, may be taken as a type. The arrangement is as follows:—

1	2	3	4
Moiety 1. (Mburi)	Moiety 2. (Umbaua)	Children.	Children.
Murungun *a* Murungun *b* Mumbali *a* Mumbali *b*	Purdal *a* Kulal *b* Kulal *a* Purdal *b*	Murungun *b* Murungun *a* Mumbali *b* Mumbali *a*	Purdal *b* Kulal *a* Kulal *b* Purdal *a*

There are four classes; but each of these, though there is no actual name for them, is divided into two, distinguished by the letters *a* and *b*. The arrangement has the appearance of being very definitely thought out, and there is, further, a very definite scheme, by means of which the divisions (Murungun *a*, *b*, etc.) are made to fit in with the corresponding sub-classes in other tribes with whom the Mara constantly come into contact.

(5) *Abnormal tribes in which class organization has apparently been superseded by some form of local organization.* As an example of these we may take the Kurnai tribe which, many years ago, occupied the mountains in eastern Victoria. It was divided into five groups, named after the localities in which they lived. There was no class organization, and a man could not marry a woman of his own local group. There were intermarrying local groups, marriage being by elopement. The Kakadu and allied tribes, living at the other extremity of the continent on the Coburg Peninsula and Alligator Rivers, have apparently no class organization, and the totem does not regulate marriage. The tribe is divided into local groups, and a man of one local group takes a wife from another particular group, the children passing into that of the father.

W.B.S.

Totemic Systems and Totemism. In dealing with Australian tribes the word 'totem' has been applied in at least three different senses: (1) the *Group totem*, that is, the material object giving its name to a group of individuals who commonly believe themselves to be descended from it. The name of the totem usually, but not always, passes by inheritance from generation to generation, sometimes in the maternal, sometimes in the paternal line; (2) the *Sex totem*, discovered by Dr. Howitt in the Kurnai and Wotjoballuk tribes in Victoria, where it exists side by side with the group totem. The women have one animal, such as the owlet nightjar, associated with them and the man another, such as the bat. This is of rare occurrence, and it may be doubted whether it should, strictly speaking, be regarded as totemic; (3) the *Individual totem*, usually acquired by dreaming of some animal. This also is of rare occurrence, and doubtfully totemic in the strict sense of the term. So far as Australia is concerned, it is advisable to restrict the term 'totem' to the first of these, and to define it as a material object (*a*) which gives its name to a group of individuals and (*b*) the name of which is usually hereditary either in the maternal or paternal line; and to restrict the term 'totemism' to a system based on the recognition of these two factors. It must be remembered that there are very considerable variations in regard to totemic customs and beliefs in different tribes.

In Australia totemism may be dealt with under three aspects, social, ceremonial, and magical. By the 'social' aspect is meant the division of the tribe into totem groups, their influence, if any, on marriage, and the mode in which each individual becomes associated with any one of them. Most tribes are, as aforesaid, divided into moieties, and these into classes. As a general rule, the totemic groups are distributed between the two moieties in such a way that each group is confined to one or other of them. The following tribes from different parts of the continent are typical of the more important variations in regard to the social aspect. (1) The Dieri are representative of tribes in which the moieties are not divided into classes. These moieties are called Kararu and Matteri, and the totem groups are divided between them. Kararu has rain, carpet-snake, crow, frog, etc., Matteri has cormorant, emu, eagle, hawk, native cat, etc. A Kararu man must marry a Matteri woman, but is not restricted in his choice to any one totem group. The children follow the mother's totem. (2) The Kamilroi are representative of a large number of tribes occupying a vast area of country in the interior of New South Wales and Queensland. The totems are divided between the moieties and the children take the mother's totem. (3) The Arunta are representative of an important group, including the Arunta, Ilpirra, Unmatjera, and Kaitish tribes. There are four classes or eight sub-classes, and the totem groups are not restricted to the moieties. Each group is, however, always more largely represented in one moiety than the other. Marriage between individuals of the same totemic name is not forbidden, but rarely takes place. The country occupied by the Arunta is dotted over with special spots inhabited by the spirits of old totemic ancestors, who enter women and undergo reincarnation. The traditions are very precise in re-

gard to these totemic centres so that the natives —knowing, or thinking they do, where any particular spirit-child entered a woman—are able to assign its totem to it. In the Kaitish, the most northern of these tribes, the totemic groups are more nearly divided between the moieties than in the Arunta. A man very rarely marries a woman of his own totem, and there is a strong tendency for the descent of the totem to be in the male line, as is always the case in regard to the class names. Each individual is normally associated with one totem group. (4) The Warramunga are representative of the Warramunga, Tjingilli, and other tribes occupying a large area in the centre, and extending across to the Queensland border. The totem groups are strictly divided between the moieties. A man may marry a woman of any totem in the moiety to which he does not belong, provided she belongs to the right class. Strict paternal descent of the totem is nearly, but not quite, the rule, but every child belongs to a totem group in his father's moiety. For example, a black snake man's children are almost always black snake; in rare cases one of them may belong to another totem group. As the moieties are exogamous, it follows that the totems are the same. (5) The Binbinga are representative of a group of tribes that occupy the country drained by the McArthur River. Their organization is closely similar to that of the Warramunga, but in these tribes not only are the totem groups divided between the moieties, but the descent of the totem name is strictly in the father's line. (6) Among the Kurnai in Victoria and the Kakadu on the northern coast-line there is no class system, and marriage is regulated by the existence of local intermarrying groups. In the Kakadu each spirit-individual has a double nature; one part enters the woman, one part remains outside. It chooses its own totem, and the spirit-part that remains outside tells the father the totem name of the child.

The ceremonial aspect has probably been very strongly developed throughout Australia, though it has only been studied in detail during recent years, when, unfortunately, in the whole of Victoria and New South Wales and in most parts of Queensland the tribes have become decadent. One of the earliest accounts that we have of the natives—that given by Collins in 1798—evidently describes a totemic ceremony. Speaking generally, it may be said that every totemic group has certain ceremonies associated with it, and that these refer to old totemic ancestors. In all tribes they form part of a secret ritual in which only initiated men take part. In most tribes a certain number are shown to youths during the early stages of initiation, but at a later period they see many more. In the Arunta, for example, the final stage is concerned with the Engwura, and this may extend over a period of three months, during which totemic ceremonies are enacted daily. To start an Engwura, the leader of some totemic group, after consultation with those of others, sends out a messenger called Ilchinkinja, which means 'the beckoning hand.' He carries a churinga (that is, a flat wooden slab commonly known as a bull-roarer), and passes over the country delivering his message at different camps. Slowly the natives gather together at the chosen place, where a special ceremonial ground has been prepared. The Panunga-Bulthara camp together, as do the Purula-Kumara, the division of the tribe into two moieties being very marked during the Engwura. Large numbers of churinga are brought in and stored on two platforms far from one another. These are associated with the old ancestors and their living representatives; and at times the old men call some of the younger ones together, rub the sticks with red ochre and tell their pupils all about the ancestors. Each ceremony is concerned with an ancestor, and is the property of some old man who either performs it himself or invites a younger man to do so. After the performance its meaning is explained. A characteristic feature of these ceremonies, the exact nature of which varies much in different parts of the continent, is that one or more men have bodies decorated with a design especially associated with the ceremony. Even more elaborate designs may sometimes be drawn on the ground.

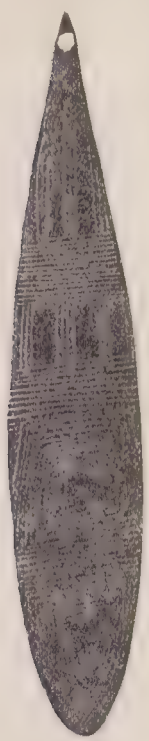
As for the magical aspect, in early days Grey (who used the Western Australian word Kobong for totem) stated that 'A certain mysterious connection exists between a family and its kobong, so that a member will never kill an animal of the species to which his kobong belongs, should he find it asleep; indeed, he always kills it reluctantly, and never without affording it a chance to escape. This arises from the family belief that some one individual of the species is their nearest friend, to kill whom would be a great crime and carefully to be avoided.' This idea of a close association between an individual and his totem is widely spread, but the exact beliefs and customs in regard to them differ very much in different parts. The general idea may be summed up in a remark made by a 'kangaroo' man, who, when looking at his photograph, said 'That is just the same as me, so is a kangaroo.' In some tribes there is a feeling of mutual protection between an individual and his totem, but this is not often met with. They are of the same flesh, and the belief in the descent from the totemic animal is widespread. In some tribes the individual will not kill his totem, but in most there is no objection to his doing so and handing it to others to eat. In some he will both kill and eat it. Speaking generally, the magical aspect of totemism appears to be largely associated with climatic conditions, so far as they affect the supply of food and water. Three typical examples of ceremonies will serve to show the nature of the magical aspect. In the Urabunna tribe, which counts descent in the female line, the ceremony is called Pitjinta. In a 'snake' group the decorated performer kneels down and extends his arms. The skin on each forearm is then pinched up, and he pierces it with a pointed bone.

When snakes become plentiful, men who do not belong to that totem group bring some to the old man and say, 'Look, here are snakes.' He smears a little fat over his arms and the bone, and tells the men to eat the rest. The bones are wrapped in the hair of a 'snake' man and put away. Among the Arunta the ceremonies are called Intichiuma. In that of a 'grub' group the men of the totem fasting, devoid of arms and ornaments, and characteristically marked, go in silence to a cave in which a large stone represents the adult insect and smaller ones its eggs; here they chant refrains, the burden of which is an invitation to the insect to come and lay eggs. Further ceremonies are performed in a long bough hut, supposed to represent the chrysalis case, built for the purpose near the camp. Some time later, when the grub is plentiful, they collect large numbers, return to camp and cook them. The head man eats a few, gives some to a few of the older men, and hands all the rest to those who do not belong to the group, telling them to eat it. The 'grub' men are not absolutely forbidden to eat, but do so sparingly. In the Kakadu tribe,

in the far north, there is a ceremony called Muraian that is evidently of the same nature—though it is not so detailed, owing, doubtless, to the normal abundance of food in this part. The natives have a large number of sacred sticks and stones, each supposed to represent a totemic animal or plant, which may only be seen by the elder men. During the ceremony they are grasped in the hands of men who dance round and round a central figure, stretching out the symbolic objects and yelling 'Brau, brau,' which means 'Give, give.' It sounds almost like a command to the totemic object. In Western Australia also, in the East Pilbara tribe, there are certain local totem centres (called Thalu) where ceremonies for the increase of the totemic object are held; in these women and children take some share—an abnormal usage. In many tribes the natives firmly believe that by means of magical ceremonies such as these they can control their food supplies. This belief was probably at one time widespread in Australia.

W.B.S.

Initiation. In all Australian tribes special ceremonies of an important nature, which vary much in detail, attend both the initiation of youths to the status of men and that of girls to the status of women. In the case of the youth, initiation is associated with showing him the 'bull-roarer' for the first time. In different parts it is called churinga, tundun, kunapippi, etc.—but its form is constant. It is a slab of wood (or, more rarely, of stone) pierced at one end. Through this hole a string is passed, and by this it is whirled round and round, making a noise supposed by women and children to be the voice of a great spirit that takes the youth away and initiates him. It is very difficult to understand the wide divergence in the initiation ceremonies of different groups of tribes. We have, generally speaking, three main types—(1) the knocking out of an incisor tooth, as amongst the Kurnai in the south-east; (2) circumcision (followed in many, but by no means all, cases by sub-incision) amongst tribes occupying a vast area in the interior of New South Wales and Queensland, the whole of the central area, and probably a large part of Western Australia; (3) special ceremonies amongst groups of tribes, such as those on Melville and Bathurst Islands and the Kakadu nation on the Alligator rivers, amongst whom no mutilation of the body (other than, perhaps, the pulling out of hairs) takes place.



Bull-roarer.

The Kurnai type is of historic interest, because in connection with it the first adequate account of initiation was given by Howitt, who also drew attention for the first time to the importance of the bull-roarer. Its essential parts are (1) the summoning of the tribesmen with a tundun, which may take months; (2) the assembling of candidates among the women on a specially cleared space, the bunan; (3) the assemblage of the men in a bush-house containing figures of totems and of Daramulun, who is regarded as the great father of the tribe; (4) the actual initiation, beginning with instruction of the candidates in tribal legends and laws, after which the women are scared away with a bull-roarer, the youths are taken to the bush-house, and on returning have the left upper incisor knocked out. Further instruction follows, and the initiated youths, now independent of the women, run off into the bush.

In the second type (including the tribes of central Australia and many Queensland tribes) there is a succession of initiation ceremonies taking place at various ages. The Arunta may be taken as a specimen. There is (1) painting the young boys and throwing them in the air, (2) the ceremony of Lartna or circumcision, (3) that of Arilthа or sub-incision, and (4) the Engwura. In connection with the second, the youths are shown the bull-roarer for the first time. In connection with both (2) and (3) they are shown sacred totemic ceremonies, and instructed in the laws, totemic history of the tribe, food restrictions and their duties as men; they are told that they must implicitly obey the old men; must not eat forbidden foods, but may supply other men with them; and on no account must they talk to lubras about what they have seen. Everything is made as impressive as possible, and the fact that the main ceremonies take place during the night, or just at daybreak, adds to the feeling of mystery. The boys have special designs painted on them, may not speak to any one save the old men in charge of them, are given very little food to eat, and pass through sundry other experiences, including being lain on by four to ten men, circumcision, and at a later stage sub-incision (Arilthа). The final ceremony, called Engwura, may be delayed until the candidate is 25 or 30 years old. After it he becomes as 'ertwa mura oknira'—very good man; but, since every man must pass through all the ceremonies, all the elder men are good, so that there are in addition grades of goodness. Those who are insufficiently interested in the ceremonies, and are given to chattering like women, are called 'irkun oknira' that is, light and frivolous. Others take matters seriously, and will, as they grow older, become leaders or 'oknirabata'—great teachers. Special status-names are applied to the boy, youth and man at the time stated:—Ambaquerka at the time of growing up, Ulpmerka after this and until circumcision, Wurtja during the ceremony, Arakurta after the ceremony and until that of sub-incision, Ertwakurka after this and until the Engwura, Uliara after the latter. As in the Kurnai, so in all tribes, women take an active part in the opening ceremonies, but are rigidly excluded from the essential parts when a bull-roarer is used. Usually some special ceremony symbolizes the fact that the boy is being withdrawn from the ranks of the women. For women, too, there are special initiatory ceremonies, in many ways analogous to those of the men. Fuller accounts of all these ceremonies will be found in the books by Howitt, Roth, and Spencer and Gillen, named at the end of this article.

The third type includes various coastal tribes, evidently much modified. A characteristic group of these inhabits the Coburg Peninsula, the Alligator River district and the coast as far as Darwin; a still more modified group inhabits Melville and Bathurst Islands. The former have a remarkable series of totemic initiation ceremonies; there is no knocking-out of teeth, and no mutilation of the body, except the pulling out of hair.

Among the Kakadu totemic ceremonies are shown to the novices on a special ground called 'ober.' There are various grades, the last of which (Muraian) is not passed through until a man is old. Among the Kakadu apparently no bull-roarers are used; but among the Larakia, at Darwin, at one stage three or four old men suddenly emerge from the bush and whirl them in front of the novices. At other stages the novices are subjected to rough treatment, such even as being kicked and hit hard, but they must not grumble or find fault. On Melville Island the novices are shown a special ceremony; the whole tribe is assembled in a camp, ceremonies are performed, and the yams cooked and eaten in a special way. The novices are also taken to a waterhole, where those who are passing through for the first time have their heads placed in bark baskets and dipped under the water, while those who have reached the second stage are caught hold of by the arms and legs and pulled violently backwards and forwards through the water. Amongst these tribes girls of corresponding status to the youths are specially decorated and take part in the ceremonies.

All the types of initiation ceremonies for men agree in certain fundamental points:—(1) They begin at the age of puberty. (2) During the initial ceremonies women play an important part. (3) During the essential parts women are absent; the youths are shown the bull-roarer, have the secret beliefs explained to them, and are instructed in the moral precepts and customs (including food restrictions) that they must henceforth observe under severe penalties. (4) At the close of the first part of the ceremonies (knocking out teeth, circumcision, etc.) a definite performance is enacted, emblematic of the fact that the youths have passed out of the control of the women. (5) The last grade is not passed through until a man is quite mature. W.B.S.

Beliefs. The belief in reincarnation is firmly held by all tribes, from the Urabunna in the south right across the continent to those inhabiting the Coburg Peninsula. The Arunta believe that in far past times their ancestors (who were endowed with powers much superior to those of their living representatives) wandered across that country in groups, 'kangaroo' men and women in one, 'witchetty grub' people in another, 'emu' people in another, and so on; the track followed by each group is well known. Where they halted, some went into the ground, their spirit parts remaining above, each in company with a churinga. The whole Arunta country is thus dotted over with local centres—one haunted by kangaroo, another by grub spirits, and so on. At the present day these spirit children are continually undergoing reincarnation. Each spirit has another associated with it, called Arumburinga, which is its double and always remains outside, living at the old camping-ground of the spirit when the latter is reincarnated. Many of the most important ancestors are known by name, and the old men decide whether a child is the reincarnation of any particular one; in that case the child bears his or her name. This name, however, is not used in public; it is secret, and known only to the old men of the totemic group. The woman never knows it, the man only when he is fully grown, and it is never mentioned except in whispers. When a child is born, one or two of the old men actually go out in search of the churinga. Sometimes they find it; sometimes they do not—in which event they make a new one, so that each individual is represented by his or her churinga in the local storehouse, called Ertnatulunga. A woman going near one of these places is always liable to be entered by a spirit child. Whenever a native dies, his spirit goes back to its old camping-ground, and remains there until it chooses to be reincarnated.

In Queensland the Tully River blacks believed that children result from one or other of four causes—(1) a woman sits over a fire on which she has roasted a piece of fish that has been given to her by her husband; (2) she goes out hunting and catches a special bull-frog; (3) some man tells her to have a child; or (4) she dreams that a child has gone inside her. The Cape Bedford blacks believe that spirit children enter the mother in the form of a curlew, if they be girls, and in that of a snake, if boys. If they hear the curlew whistling at night they say 'Hallo, there is a child about.' According to the Pennefather natives, a mythic being called Anjea makes children out of swamp mud and puts them in the mothers. He is never seen, but can be heard laughing in the scrub. In the Warramunga tribe, each totemic group is supposed to have had one great ancestor who wandered over the country, performing ceremonies at different spots, where he left spirit children behind; it is these who are born again. In the Gnanji tribe there is the same belief; but, in addition, if a man travels, spirit children from his own place may follow him up and go inside his wife.

In the Kakadu tribe the beliefs are very precise and detailed. There are supposed to have been a limited number of ancestors, who deposited spirit children at different places. These have been continually undergoing reincarnation. The names of all are known, and every individual now bears the name of one of them. There is no secrecy in connection with this. When a man dies, the spirit part stays with his bones after the mourning ceremonies are over, forming what is called a Yalmuru. This gives off a double of itself, somewhat like the Arumburinga in the Arunta, but here called Iwaiyu. It is the latter that enters a woman and undergoes reincarnation. Later on again, the original Yalmuru, who watches over the man or woman during his or her lifetime, is supposed to become worn out, so that when the man dies the old Iwaiyu becomes the new Yalmuru, which in course of time produces a new Iwaiyu, and so on, generation after generation.

In the Broome district of Western Australia, the natives believe that every child must be 'dreamed' by his father, and the 'dream-baby' is called Ngargarula. If the latter does not appear to the father, and his wife gives birth to a child, he does not believe that the child belongs to him. If, on the other hand, a man is separated from his wife for a long time, and while he is away a Ngargarula comes to him and his wife has a child, he believes this belongs to him, no matter how long a time he may have been separated from his wife.

All over Australia, too, the natives appear to believe in beings endowed with powers superior to their own. In the Narrinyeri tribe in South Australia a being called Nurrundere was supposed to have made everything, and to have instituted their rites and ceremonies. The Wotjobalƚuk in Victoria spoke of Bunjil as 'our father,' and the Kulin people believed that he was an old man with two wives, who taught them the arts of life and divided the tribe into intermarrying groups. Among the Kurnai, Bunjil was a great being,

all knowledge of whom was confined to the men. The Kamilroi looked on Baiame as the being who created all things. Amongst the Yuin people Daramulun is supposed to have instituted the ceremonies and made the bull-roarer. He lived in the sky, watching the men. His name is only used by the initiated. In parts of Queensland they believe in Kohin who lives in the Milky Way, roams about at night as a warrior, killing all natives he meets, and is offended if they do not keep the customs. The Kabi and Wakka tribes believed in beings such as Biral, Jonjari and Dhakkan, who was identified with the rainbow and lived in deep waterholes. He could shatter mountains and slaughter natives, and was at times malignant. He substituted half-caste for pure-bred children—so he was called Warang (wicked).

In the central tribes there is everywhere a belief in the former existence of ancestors endowed with superior powers. But there are other superior beings. The Arunta believe that long ago there were two, called Ungambikula ('made out of nothing'). They lived in the sky, came down and made men and women, and then turned into lizards. The Arunta also believe in the existence of mischievous spirits, called Oruncha, who are always ready to injure natives; but they have no great spirit such as Baiame. They have a mythical being called Twanjirika, who is supposed by the women and children to take the boys away at initiation and provide them with new 'insides,' and whose voice is heard when the bull-roarer sounds. The men, however, tell the youths that the sound is made by the roarers. There is a belief amongst the Kaitish tribe in a being called Atnatu. He made himself, the stars are his wives, and he has plenty of sons and daughters. Long ago he was angry with his children, so he dropped them down on earth, and, with them, everything the natives now have. If he hears the bull-roarers he is pleased, if not he is angry. The Binbinga on the Gulf of Carpentaria believe that there are two malignant spirits called Mundagadji, anxious to hurt them, and a friendly one, named Ulurkura, who lives in the woods and stops the Mundagadji.

Speaking generally, it may be said that every tribe has a belief of some kind in superior beings; that, with rare exceptions, the latter are not supposed to take any personal interest in the natives or to be pleased or displeased with what they do; that no appeal for help is ever made to them; and that they have nothing whatever to do with the inculcation of moral precepts. W.B.S.

Magic, and Medicine Men. It is difficult to overstate the part that magic plays in a blackfellow's life. From the moment that he is born until he dies he lives in an atmosphere of magic. There are two sides to it, the evil and the good; the former bulks more largely in the blackfellow mind. Of good magic we have, on the one hand, ceremonies such as those in which a man of the 'yam' totem will take one of his yam churinga, 'sing' it and then deposit it on ground where yams are usually found, with the idea that he can thereby make them grow; on the other, we have magic called into existence to counteract evil magic. In some tribes any man, or even woman, may perform evil magic; in others the power is confined to the medicine men—as is also, in all tribes, the exercise of curative magic. Medicine men are made in various ways. Sometimes an old medicine man will initiate a young man; more often they are supposed to be made by supernatural beings of some kind; and in most, if not all, cases the medicine man has in his body something in the form of small crystals. These are the seat of his 'virtues,' and can be projected into the body of the patient, in whom they may either cause trouble or counteract evil magic implanted by some other individual. The medicine men also communicate with the spirits, and only they can withdraw 'poison bones and sticks.' They often fly into the sky during the night, visiting hostile camps and inserting bones and sticks into enemies. Sometimes by means of invisible ropes they climb up and down between earth and sky. Some are even strong enough to ward off evil magic from a whole tribe. At the time of the 1901 comet a powerful Kaitish medicine man saved the whole tribe from destruction by night after night 'singing' the comet's tail, and preventing the spears, of which it was made, from being hurled on to the Kaitish country.

The commonest form of evil magic is associated with pointing bones and sticks. A typical form (munguni) from Queensland may be taken as representative of this form. The instrument consists of a short pointed bone attached to a string that passes into and through a little hollow receptacle, made of bone or wood, and out at the opposite end, which is then closed. When in use, the receptacle is held in one hand and the bone pointed towards the victim, who may be miles away. A double action takes place; some of the victim's blood is drawn into the receptacle, where it is sealed up, and at the same time evil magic passes out into the victim. To kill the latter, the receptacle with its contents may be burned; just to keep him ill, it may be warmed every now and then. He will never recover until it has been thoroughly rinsed out.

Another characteristic form is associated with an object called tchintu. It is only a small lump of resin with two teeth in it, and a long string attached; but by being 'sung' the heat of the sun can be drawn into it, and then, if it be placed in the tracks of anyone, the heat follows the victim up, enters the body and kills him.

Some of the most potent forms of magic are associated with objects containing hair cut from the bodies of the dead. Used on avenging parties, they both endow the wearer with strength and accuracy of aim and at the same time render the victim powerless. Another favourite and widespread practice is that of 'taking the kidney fat.' This is usually done by a hostile medicine man. In the Wotjoballuk tribe he sneaks on the sleeping victim, carrying a magic bone with a noose attached to it. He may either project the bone into his victim—which action compels him to come out to the medicine man, who then throws him over his shoulder and carries him off—or, if in camp with his victim, may pass the bone under his knees when he is asleep, round his neck and through the noose, rendering him helpless. In any case the victim is unconscious of what takes place. The medicine man opens the right side of his victim just below the ribs, and abstracts the fat, which may be eaten or rubbed on weapons. The wound is 'sung' and the sides bitten together in such a way that no scar is left. The victim wanders back to camp, but soon dies. No medicine man can cure one whose kidney fat has been extracted; but he can determine—even the patient himself may —who is the guilty one. Any medicine man can withdraw bones and objects of magic generally, and is always called in when a patient is ill. No native believes in illness except as the result of evil magic, and magic from a distance is always potent. Pain is caused by some concrete thing

that must be removed from the body; the method of procedure is very much the same in all tribes. The patient lies down; the medicine man comes up and gazes fixedly upon him, as often as not projecting some magic crystals into him as an antidote. Then, after prolonged sucking and massage, he will, perhaps (but only if he be a very gifted practitioner), withdraw the poison-bone or stick whole; in most cases it is removed bit by bit. Then, unseen one by one, his magic crystals return to his body. W.B.S.

Burial Ceremonies. Death is always supposed to be due to evil magic, and may be brought about in various ways. Very often a bone or stick is 'sung' and pointed in the direction of the victim, whom its evil magic then enters. In some tribes a ceremony is performed with the object of catching the double of the man's spirit, without whose friendly guidance he meets with an accident. Death is always a source of fear to natives, because in many cases it means not only that there is some evil spirit or magic influence at work, but also that the spirit of the dead person is hovering about. It is customary to shift camp the moment a death occurs, and in almost all tribes special ceremonies must be carried out. These vary very much, as do the methods of dealing with the body, in which at least seven main types, with many variants, may be recognized. (1) *Simple earth burial.* This takes place in many tribes all over Australia, of whom the Arunta may be taken as a type. First of all, the deceased's hair is cut off and made into a special girdle, filled with magic, to be subsequently worn by a man who avenges the death. The body is buried in the ground in a sitting position, with the knees doubled up against the chin; the earth is piled up to make a low mound, with a depression on one side to allow of ingress and egress of the spirit. The camp is burnt down, and in the case of a woman everything is destroyed. No person may mention the deceased's name during the period of mourning; if any one does, the spirit hears, thinks they are not mourning properly, and is angry. In the case of a man, those who might legally be his sons-in-law neither mention the name, nor attend the funeral, nor take part in the ceremonies; but they must cut their shoulders. The actual widow or widows paint themselves with pipeclay, and are called inpirta ('whitened one'). They must not speak until, at a later period, a ceremony is performed to remove the ban of silence; this ceremony shows that the widow is about to resume her ordinary life, and later on she will become the wife of one of the younger brothers. At least a year after death the ceremony of urpmilchima (trampling the twigs on the grave) is performed. The widow smears herself over with pipe-clay and, wearing a chaplet made of clusters of small bones that hang down over her face, accompanies the other men and women first to her late husband's camp and then to the grave, which they approach yelling, so as to drive the spirit ahead and into the ground. After cutting and wailing, the chaplet is broken and buried in the grave, by the side of which the widow rubs the pipeclay off, and her mourning is over. The spirit sees that it has been properly mourned for, and returns to its ancestral home, where it lives until it undergoes reincarnation. The most elaborate earth burial occurs on Melville and Bathurst Islands; there very definite and highly decorated grave-posts are erected, around which the mourners dance. (2) *Burning the body.* This was carried out both in Victoria (Ovens River district) and New South Wales (near Sydney). The calcined bones were, in some cases, placed in the hollow branch of a tree. (3) *Burial on a tree platform.* This custom is widely spread. The Narrinyeri and Encounter Bay tribes of South Australia may be taken as examples. Among the former, the apertures of the body are sewn up and it is placed on a platform, under which a fire is lighted; the relatives sit beneath. In the latter the skin is scorched off by fires and sun, and then the remains are placed on a platform. (4) *Temporary burial on tree platform and subsequent disposal of bones.* The Warramunga (central Australia) is a typical example. Immediately after death the body is placed on a platform of boughs in a tree. When the bones are clean, they are all raked out, and the skull is smashed; then, with the exception of one arm-bone, they are buried in an ant-hill. The arm-bone is brought into camp, and handed over to the mother of the dead person. At the close of a ceremony connected with the totem of the deceased it is broken in two and buried in the ground. (5) *Eating the flesh, followed by platform- and subsequently coffin-burial.* This occurs amongst the Mara, Anuta, Binbinga, and other tribes on the western side of the Gulf of Carpentaria. The eating is strictly ceremonial. The bones are wrapped in bark and placed on a small platform. They are finally enclosed in a log coffin decorated with the totemic design of the deceased; this is placed either by the side of a water-hole, into which it is swept at flood-time, or in a cave amongst the rocks. (6) *Mummification.* This is met with chiefly in Queensland, the dried body being attached to a kind of small scaffold. (7) *Leaving the body in the open.* This occurs very rarely, as in the Yercla-mining tribe on the coast of the Australian Bight. W.B.S.

Manners and Customs. The task of gathering information regarding the manners and customs of aborigines is beset with difficulty. In the first place, a blackfellow desires to please, and will give the answer that he thinks his questioner wants. Secondly, his answer may be entirely misunderstood: for example, the name of a river may be stated on the authority of a blackfellow to be such and such, the word really meaning 'I don't understand.' Thirdly, both in regard to information supplied by the blackfellow and in regard to what an observer sees for himself, what is true for one tribe may be quite misleading when applied to another in close proximity. Writers are often right in what they affirm, but very apt to be wrong when they begin to deny.

The aboriginal is a wandering hunter, a gatherer of such things as Nature produces for him without any special foresight on his part or any effort except what is required for the capture or the search. He is not an agriculturist in any sense; 'settled agriculture' for the blackfellow in his native condition would have been impossible as a means of subsistence. Even when civilized and apparently domesticated, he has an intense and irresistible longing to 'go bush,' and becomes really ill if this homesickness is not satisfied. A blackfellow who can continue at laborious work for any length of time without growing bodily ill is a rare curiosity. The lack of domesticated animals is often instanced as evidence of the aboriginal's inability to domesticate animals. But where were the materials to work upon? Who that

knows Australian fauna can imagine any aboriginal endeavouring to plough with a kangaroo or trying to milk a wallaby? When horses were introduced, the blackfellow proved himself unsurpassed in the art of horsebreaking and managing all varieties of imported domestic animals. The men pass their time in hunting, fishing, fighting, and making arms and implements. The women gather and prepare food, make nets and bags, and attend to the children; on the march they are the camp-baggage carriers. A good idea of their relative occupations and duties may be gathered from Grey's accounts of their equipment:—

> The Australian hunter is thus equipped:—round his middle is wound, in many folds, a cord spun from the fur of the opossum, which forms a warm, soft and elastic belt of an inch in thickness, in which are stuck his hatchet, his kiley or boomerang, and a short heavy stick to throw at the smaller animals. His hatchet is so ingeniously placed, that the head of it rests exactly on the centre of his back, whilst its thin short handle descends along the back bone. In his hand he carries his throwing-stick, and several spears, headed in two or three different manners, so that they are equally adapted to war or the chase. A warm kangaroo skin cloak completes his equipment in the southern portions of the continent; but I have never seen a native with a cloak, any where to the north of 29° s. lat. . . . .
>
> The contents of a native woman's bag are:—A flat stone to pound roots with; earth to mix with the pounded roots; quartz, for the purpose of making spears and knives; stones for hatchets; prepared cakes of gum, to make and mend weapons, and implements; kangaroo sinews to make spears and to sew with; needles made of the shin bones of kangaroos, with which they sew their cloaks, bags, &c.; opossum hair to be spun into waist belts; shavings of kangaroo skins to polish spears, &c.; the shell of a species of muscle to cut hair, &c. with; native knives; a native hatchet; pipe clay; red ochre, or burnt clay; yellow ochre; a piece of paper bark to carry water in; waistbands, and spare ornaments; pieces of quartz, which the native doctors have extracted from their patients, and thus cured them from diseases; these they preserve as carefully as Europeans do relics. Banksia cones (small ones), or pieces of a dry white species of fungus, to kindle fire with rapidly, and to convey it from place to place; grease, if they can procure it from a whale, or from any other source; the spare weapons of their husbands, or the pieces of wood from which these are to be manufactured; the roots, &c. which they have collected during the day. Skins not yet prepared for cloaks are generally carried between the bag and the back, so as to form a sort of cushion for the bag to rest on. In general each woman carries a lighted fire stick, or brand, under her cloak and in her hand. (Grey's *Journals*, ii. 264-6.)

Aboriginal hunting is not a mere matter of endurance, speed, or accuracy of aim; it is observation brought to a fine art and acted upon. The blackfellow knows the track, cry, and habits of every animal, and takes advantage of its every peculiarity or characteristic to secure his prey. He will track the opossum by its claw-marks on a tree-trunk, or by observing the flight of mosquitoes if no claw-marks are visible. He will decoy pelicans within his reach by imitating the jumping of fish, throwing mussel shells or splashing the water with his fingers. Being almost amphibious in habit, he will creep or swim up to ducks with grass round his head, and pull the birds one by one under water, breaking their necks and letting them float till he has enough. He will find and capture snakes by watching the movements of their companions the butcher-birds. He will catch a bee, stick a piece of feather or down on it, let it go, and follow its flight until he finds its hive and honey. He will walk into the sea at a place where a white man cannot see a single shell, and in a few minutes, by digging in the spots of yielding sand with his feet or fingers, will find enough cockles for a meal; in short, he will find abundance and live at ease where a white man would see nothing and starve to death. His power of tracking is due to observation and not to instinct, although the process may be to some degree unconscious; a white man can learn the art without very much difficulty. His ingenuity is seen almost as much in fishing as in hunting. Hooks made of shells or tortoise-shell, harpoons, spears, baskets, cages, nets, hollow-log traps, weirs, dams, fences and poisoning are all employed as a means of obtaining fish. The remora or sucker-fish, with a string attached to its tail, is used as a guide to direct him to turtle, dugong, or other fish.

It often happens that one tribe wishes to pass into or through the country of another for the purpose of gathering food, or obtaining it or other necessaries by barter. On such occasions a very rigid etiquette is observed. A messenger is sent in advance, dressed elaborately in emu feathers or other recognized ornaments and bearing as credentials a message-stick somewhat larger than a finger, or a 'pass-it-on' cubical stone about three-quarters of an inch in size. Message-sticks are also used between members of the same tribe. While the subject has not been thoroughly investigated, and the markings on the sticks may have some meaning comparable to our written messages, it is now usually held that they have no significance apart from what may have been agreed on beforehand between sender and receiver. 'More than anything else' says Roth, 'the stick acts as a sort of guarantee of good faith, to show there is "no gammon," and may at times act as a safeguard or passport over otherwise hostile country; there is nothing on it in the form of a communication which can actually be read, the messenger invariably carrying the message by word of mouth.' It is known that a great system of trading and bartering exists, but it has been hardly investigated at all except by Roth in northern Queensland; one recognized trade-route involves nearly 500 miles of travel, but in most cases the tribes do not move far outside their own territories, acting rather as carriers of desired goods between natives on one side and on the other.

Their fighting customs are somewhat peculiar. One does not find one tribe carrying on a well-directed or continued war of extermination or of vengeance against another. The reasons for a fight are clearly recognizable, and its beginning, its form, and its end can all be predicted, whether it be between individuals or tribes. The rules or conditions of fights appear to be as definite as those of tournaments or duels.

The extremely complicated rules, varying with different sets of tribes, which dominate marriages among the aborigines are discussed fully in a previous section on *Organization*. The underlying principle appears to be prevention of in-and-in-breeding, but the proper distribution of the food-supply seems to be also involved in some cases. In some tribes there is a provision for the compulsory marriage of cousins—a man must marry his mother's elder brother's daughter; this is especially interesting in connection with the study of Fijian customs, which make marriage of the children of brother and

sister compulsory, that between the children of two brothers or of two sisters being prohibited. In Fiji the progeny of these compulsory unions is said to be exceptionally vigorous and fertile.

Allegations sometimes made that the aborigines lack morals and allow promiscuous intercourse are wholly mistaken. The penalties of adultery, incest (i.e. illicit relations between members of the same phratry, etc.), seduction of the immature, and so forth, are severe and may involve death; whatever they are, they are strictly enforced. Crimes against nature seem unknown.

The aboriginal child, like all children of uncivilized races, comes into the world very easily. The mother may be at her duties a few minutes after its birth, which is hardly an incident in the routine of the camp or the march. A blow on the head may terminate its existence, if its mother be young or if it be likely to encumber the parents. Women may bear as many as 15 children; the average is about five; but in many places only two of these would be reared. Twins occur. The future of female children is determined according to their relations to their husband and his relatives, not by their own parents. Childhood as a rule is a happy time. The blacks are fond of their children, and seldom beat or correct them. There are many games and amusements for them. Idiocy is uncommon; mania sometimes occurs. Deaf-mutes are often very intelligent, and express themselves intelligibly.

The Corroboree appears to be a universal institution. It is 'the medium through which the delights of poetry and the drama are enjoyed.' It is also the occasion for all sorts of festivities and enjoyments, gymnastic displays and competitions, displays of dress that do not interfere with displays of the figure, religious observances, and secret rites; and it is the tribal circuit court. Full and excellent descriptions of several kinds of corroboree will be found in books by Roth and Spencer and Gillen.

W.R.S.

Dwellings, Food-supply, etc. A blackfellow camping for the night usually makes, before darkness sets in, a break-wind of bark, boughs, or bushes on the side from which he expects the wind to blow during the night. His forecast is almost invariably correct: if there should be occasion to alter the three-foot high erection, he can do so in a few minutes. The camp forms a greater or less segment of a circle, the convexity exposed to the wind and the fire between the occupant and the open gap to leeward. It may be so completely hidden as to elude keen search. The bed is formed of green twigs, reeds or grass. Camps intended to be less temporary usually consist of bark huts open in front. In some places bark is used almost exclusively, and makes excellent huts, since it can be procured sometimes in slabs about twelve feet long and ten broad. Overhanging rocks, hollow trees and caves are sometimes used, but caves are not in much favour. When many natives happen to camp together, there are recognized rules and customs regarding the position and arrangement of the huts and the mode in which various parties pass to and fro in camp. All boys and uninitiated young men sleep at a distance from the huts of the adults. Each inmate or family has a separate fire, or several fires. Large common fires are not used in camps. At times and in some places there may be larger huts; but the general conditions of the country make the small temporary shelters serviceable if not imperative.

The aboriginal of the northern parts wears nothing, and has no desire to wear anything—though occasionally, as among the women of Melville and Bathurst Islands, more or less efficient aprons are worn. Even civilized blacks in the north, when alone, throw off their clothing; when they hear that a white man is coming along, they make a scramble for European dress. Among southern tribes kangaroo-rugs and skins of the opossum and wallaby form the chief or only articles of clothing; a single garment is worn, varying in size according to the season, and usually oblong in form. It is worn fur-side out over one shoulder, and fastened with a wooden pin in front, so as to leave the other shoulder bare and the arm free. In some places seaweed or rushes are made into clothing, and the rough fibrous material formed by the scum of the lakes, when dried on the beach in large flat pieces, is used as blankets. No head-covering is worn or used, except at times some green bushes or wet weeds.

The scarring of the skin so commonly found throughout the continent is usually considered as ornament. The fact that the scars of adults are replaced in children by painted imitations would seem to lend weight to the explanation. It is probable, however, that this scarring, in the male at least, did not originate as ornament or art. Among some tribes in the Northern Territory the scars in women have reference to the family history of the individual, and show the number and sex of the children and whether they are dead or alive; also they indicate other relationships and widowhood. In men they do not appear to have a similar significance, and it is remarkable that they occur on such positions in the body as would brace up the joints and prevent the looseness of tissues so apt to occur in well-fed individuals, and so detrimental to their fighting powers. In this respect the aborigines remind one of the Scythians and Nomades mentioned by Hippocrates, who produced similar scarring with a very definite object in view. This subject increases in importance when one takes into account the theory of the affinities of the Caucasian with the Australian.

The ornaments most commonly seen are brow decorations made of the lower incisor teeth of the kangaroo; broad fillets of string smeared with ochre; necklaces of fur spun or twisted into string, of short pieces of the stems of grass threaded together, or of shells threaded on string; tassels of the tips of the wild dog's tail; armlets of woven grass or strips of skin; belts of scores of yards of hair or of bark carved and coloured; and pieces of wood, bones, or feathers stuck through a hole in the septum of the nose. The practice of painting and anointing the body in connection with bellicose, funeral or joyous occasions may also be included. The native is fond of his decorations, and not a little vain when wearing them.

The variety of food is enormous, both from necessity and from choice. The dietary extends from clay to kangaroo, from nardoo to honey. Roth has catalogued and described 240 edible plants and 93 species of molluscs used by the aborigines of northern Queensland. When it is considered that many of these articles of food require special methods of preparation (some necessary in order to modify their poisonous properties), it will be understood that the blackfellow's knowledge of food and cookery

is of no mean order. In some places white clay, a great delicacy, is elaborately prepared and eaten, as is also the clay that forms the outside covering of ant-hills. Among articles of food used by the aboriginal, but not usually favoured by whites, are ants, grubs, caterpillars, moths, wasp-larvae, lizards, iguanas, frogs, rats, mice and snakes. The native is sometimes pitied for having to eat such things as grubs; as well might we commiserate an Englishman for eating oysters, or a Frenchman for eating frogs. Even white children of all classes will indulge in eating tree-grubs. The native, in fact, lives well. He is more of an epicure than a gourmand. He knows what every district produces, when the products are in season, and how he can obtain them; so the varying food-supply makes him a nomad.

From our point of view he is very wasteful. He kills immature animals, and even devours young birds in the egg. It is often said that he has no foresight in the provision of food. This is a mistake; he rarely leaves the gathering or catching of food until he is hungry. On journeys he husbands his provisions with the greatest care, and in some instances looks a long way ahead. The huge beds of cockle-shells —some about a mile long and some hundreds of yards across—with ovens of flat stones in situ, found among sandhills near the shore in certain districts testify to the enormous number of molluscs gathered and cooked; and inquiry shows that the preparation and preserving of this sort of food is quite an extensive industry in those parts.

In many parts of Australia the water problem is a serious one on account of the general lack of springs, and this fact has made the aboriginal an expert water-finder. By looking at certain rushes (or other vegetation) and noting the disposition of the ground he is able to tell where and at what depth water will be found, and sinks his waterhole accordingly. Further, he has such an intimate knowledge of every foot of country, that he knows where after a shower or on a dewy morning he will find water which he can collect and store in his water-bag. In some places shells (e.g. that of *Haliotis*) are used as drinking-dishes; in others, skulls may be similarly employed. Among the Narrinyeri tribe, which lived where water was at times very scarce, skulls with the sutures sealed up were used as water-containing and water-carrying vessels. It is doubtful if such a custom obtains in any other tribe in the world. In some parts large shells (e.g. that of *Melo*) are used for water-carrying. Very commonly water-bags are made of the skins of animals. In desert places the aboriginal is able to obtain water in quantity from the long lateral roots of the gum scrub, a good root yielding about two-thirds of a pint. The captain of H.M.S. *Beagle* records that the blacks about the Gulf of Carpentaria have accustomed themselves to drink salt water almost habitually, for lack of fresh. An artificial drink is made in some places by dissolving manna or gum in water. Various plants are used for sweetening drinks.

It does not appear that the aboriginal anywhere manufactures intoxicants. The use of pituri (pitcheri) as a narcotic is very general. Tribes will send messengers hundreds of miles to obtain by barter the parts of this plant which are prepared for chewing. It produces a voluptuous, dreamy sensation. Sometimes it is smoked in pipes. In some parts, at corroborees, the natives produce a condition of frenzy by chewing the leaves of the stinging tree. Sexual stimulants are not unknown. At Port Keats, in the Northern Territory, the men use an infusion of the leaves of a plant as a local application for this purpose. In the civilized state both men and women use tobacco universally, and some are much addicted to alcohol if they can obtain it. Others acquire the opium habit, and make opium pipes out of beer bottles.

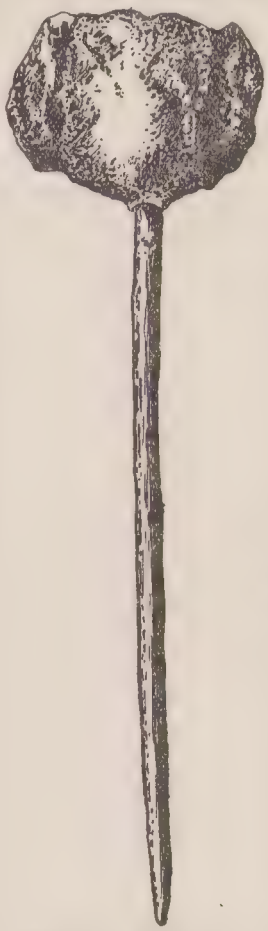
The subject of medicine is much bound up with magic, sorcery, witchcraft, and disenchantment. Nevertheless a fairly large amount of rational or empirical medicine is practised, consisting in the use of a few animal and vegetable preparations taken inwardly, and of liniments, lotions, resins, poultices, fomentations, heat, ashes, dust, ligatures, and such-like, applied externally. Bleeding is not uncommon as a general and local remedy. Fractures are treated by splints of wood or bark and by bandages, snake-bite in various ways—sucking the wound after applying ligatures to the limb being one of the commonest and most successful. The blackfellow has very little power of resistance against what may be termed 'medical diseases,' but recovers very quickly from all sorts of surgical injuries that would almost certainly prove fatal to Europeans under treatment. I have found skulls that obviously had been trepanned and had healed.

W.R.S.

Weapons and Implements. Amongst Australian stone weapons in actual use at the present time there are examples of the types known in Europe under the names Chellean, Mousterian, Aurignacian, etc. The terms eolithic, palaeolithic, and neolithic do not in Australia indicate either time-periods or levels of culture. Not only in different parts of Australia, but in the same parts, natives will use side by side implements that, if they were found in prehistoric deposits, would indicate different stages of prehistoric culture. Everything depends, in the main, on the material available. If the native lives in quartzite country, he makes chipped or flaked implements, some coarsely manufactured for temporary use, others carefully and often beautifully shaped. If he lives where he can get diorite, he grinds his tools; if he lives where he can get material suitable for both grinding and flaking, he makes tools which if found as 'fossils' would be called either palaeolithic or neolithic; the rougher ones, indeed, would be called eolithic (or rejected as non-human) by those who have never seen a native use a pebble that he has very roughly flaked to serve some temporary purpose. During ceremonies that require the cutting of a vein, a man will take from the ground any pebble that lies handy, and with another will strike off little flakes until he secures one with a sharp edge,

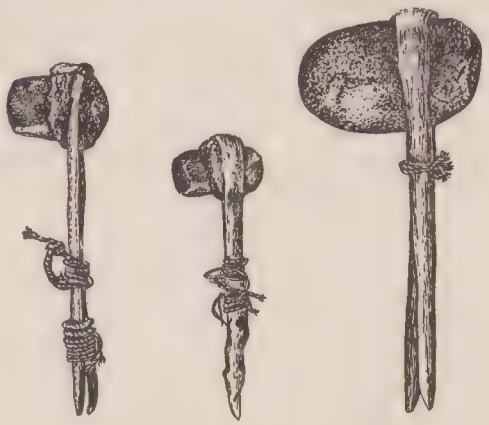
Quartzite knife, north-central Queensland.

and with this he will cut his vein open. At the present day, for example, a Warramunga man in central Australia possesses—and continually uses—a ground stone axe, a flaked or perhaps chipped and flaked axe or pick, a flaked knife hafted with resin (or with resin and wood), and, at the same time chipped stones quite as rude as—indeed, indistinguishable from—those of the old Tasmanians. It is this constant mixture of implements usually regarded as belonging to different levels of culture that forms the most striking feature of the present stone age in Australia. Without going into detail, the stone implements of the natives may be divided into three groups, according as they are used for cutting, grinding, or pounding. The cutting implements include axes, knives, adzes, and spear-heads. On the one hand, they vary in form from the crudest chip or pebble, roughly flaked on one side so as to form an axe, to delicate, leaf-like, jasper spear-heads, indistinguishable from those made by the most highly cultured neolithic people of Europe. On the other, they may be roughly chipped pebbles or blocks of stone, just showing the faintest trace of grinding, or beautifully ground and polished with a keen sharp-cutting edge. Only in very exceptional cases, however, is the whole surface ground. In some cases they were designed to be held in the hand, and show a well-marked finger grip, in others to be hafted with the aid of resin and wood. Grinding implements usually take the form of large kerns or mills, the nether stone being formed of a slab of sandstone hollowed out (often on both sides) with continuous grinding until the central crust becomes so thin that it breaks through. In some cases, as for grinding ochre, flat stones of any kind are used. Pounding implements take the form of lower stones or pestles, always with a pounding or husking hole, and of upper stones used as hammers. Outside these main groups we have such objects as playing-stones, sinkers attached to nets, etc.



Mounted Stone Axe, Western Australia.

The most characteristic weapon is the boomerang (q.v.). There are endless varieties of clubs and spears, all made of wood; the spears have barbs or blades of wood, bone, or stone. Most of them have a concavity at the handle end, into which fits the knob of a spear-thrower (wommera); but the very light cane ones, with simple sharp wooden points, as well as the great javelins of the Melville Islanders, are thrown by hand.



Mounted Stone Axes, Queensland.

The wommera is a very characteristic Australian weapon. Sometimes it is only a rounded stick two or three feet long, with a knob of resin at one end; sometimes it is leaf-shaped, either flat or decidedly concave, and is used for other purposes as well as throwing. Among the central and western tribes the weapon has a small wooden knob at one end, tied on with sinew, and at the handle end a lump of resin, into which is fixed a sharp cutting-flint. During ceremonies it serves to hold a supply of blood, down, or ochre; at other times it is used as an adze, gouge, or chisel. Altogether it forms one of the blackfellow's most useful implements.

Among other ingenious and useful implements are the wooden troughs (pitchis or coolamons) and baskets used for carrying food and water. The former are fashioned out of solid logs cut from gum-trees—or, when it is available, from soft wood such as that of the bean-tree. The perfect symmetry and shape of the hardwood troughs are wonderful, as is the regularity with which the concave lines made by the cutting-flint run parallel to one another along the length of the trough. Simpler baskets are made out of palm or pandanus leaves, the stalks ingeniously folded over; others are made from sheets of bark, stripped from a gum-tree during the wet season; others, again, are made of plaited grass or of string, so closely netted that the bags will hold fluid. The most remarkable baskets are undoubtedly those made in Queensland from split cane, with the two lower corners pointed and

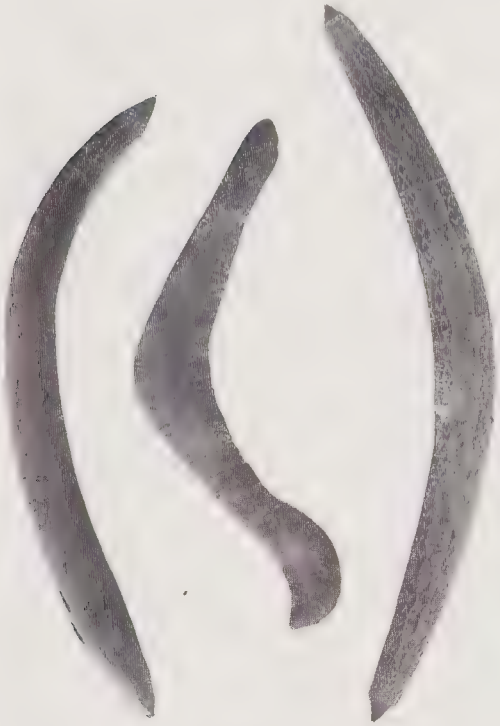
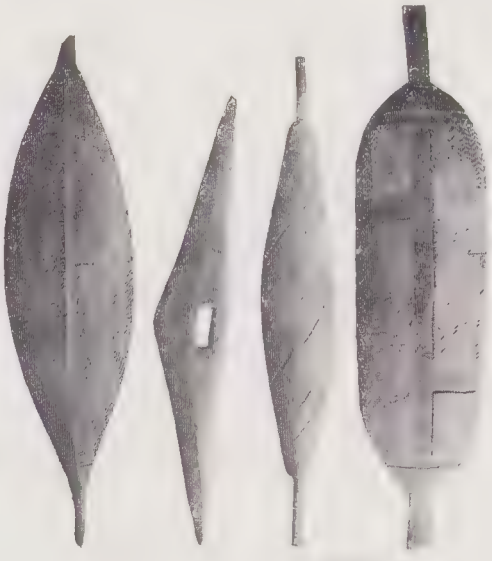
Stone-bladed fighting-pick (north-central Queensland)

Painted Shield (Cardwell, Q.)



Boomerangs



Shields (New South Wales)

upturned. Shields vary much; they may be of soft or hard wood, with handles carved out of the solid or inserted separately. For the most part they are broad, but in the south-east of the continent a narrow one was used to ward off the blows of clubs. The surface of the shield lends itself to decoration, which sometimes takes the form of incised patterns; more often, apart from the concave lines made by the flint, the design is due to pigment. Attention may be drawn to the massive shields with bold design found only in the Cairns and Cardwell districts of Queensland. The aboriginal is very clever at string-making. He uses human hair, fur of different animals, shredded leaves (such as those of the pandanus) or bark of different trees. He may use one hand to 'serve' the material and the other to rub it on his thigh, or may employ a very simple spindle. So admirably is the string made that at a casual glance it appears just the same as a white man's; it can usually be distinguished by the fact that native twine is very rarely more than two-ply, whereas the white man's is seldom less than three. It is used for various purposes, the most important, perhaps, being the making of nets and bags. Some of the larger fishing-nets measure 70 feet in length by 7 in width.

W.B.S.

Pygmy Flints. Since the year 1864, and especially since 1871, there have been many finds in various parts of the world of small manufactured stones, in length three-sixteenths of an inch, or less, and of varied forms. Various names have been given to them; they are now generally referred to as 'pygmy flints.' Very full monographs have been written on them by Coutil, Pittard, Montadon, and others, and speculation has been rife regarding their nature, uses, and anthropological significance. They have been classified according to their geometrical forms or their supposed uses. T. Whitelegge has made a large collection of specimens found near Sydney. He classifies these as surgical knives; barbed or death-spear flakes; double-edged knives; adzes or chisels; gouges; discoidal or button-shaped stones; single-edged knives; gravers; spear-scrapers; and (possibly) drills. It would be foreign to the purpose of this article to refer to the subject in any detail; the point of interest is that they have been found at various places in Australia (apparently not, so far, in Tasmania) and that in most if not in all respects the Australian specimens conform in character to specimens found elsewhere. This fact is very significant, when one considers that in all apparent essentials their structure remains constant in character from the earliest times, probably from the palaeolithic period.

Canoes are found among the lake and river tribes and on parts of the coast. They are commonly made of a large sheet of bark removed from a tree-trunk, and bent or shaped into form by heating. A large one, 20 feet long, to hold seven or eight people, can be made in a day. On some parts of the north coast there are wooden canoes with outriggers; in other parts catamarans are found, made of several logs of light wood tied together. W.R.S.

Decorative Art. The decorative art of the Australian aboriginal, so far as weapons and implements are concerned, is generally remarkable for the almost entire absence of design suggested by natural objects. In south-eastern Australia we meet with shields, etc., ornamented with conventionalized animal drawings, but they are so rare as to attract attention at once. In his rock and bark drawings the blackfellow will depict animals and plants; but, for the most part, his ornamentation of implements and sacred objects alike consists of conventional designs. Owing to lack of material, he is restricted to a few colours; red ochre, pipeclay, yellow ochre, and charcoal, are his four mainstays. Here and there he may have something like 'wad' (an oxide of manganese that gives a pearl-grey colour when powdered). No blue is ever used by the aboriginal in his native state, though he soon adopts it when in contact with white men.

A very striking feature is the use he makes of down, derived either from birds or from the involucral hairs of different plants. He mixes it with red ochre or pipeclay—never, curiously, with yellow. With the aid of such materials he produces simple, bold designs of circles, spirals, and symmetrically curved lines, showing an appreciation of strong contrasts, such as are offered by black or red circles, spiral and curved bands, outlined by white dots. So far as the nature of the design is concerned, they can be divided into three series—zoomorphs, phytomorphs, and geometrical. From another point of view, they may be divided into two series—ordinary and sacred. Of ordinary designs there are three well-marked methods of production. *Incision* by means of a sharp stone, tooth, bone, or shell. The simplest ornamentations have the form of finer or coarser groovings that run parallel to the length of the object. These do not necessarily give rise to a pattern. In olden days the tribes on the Murray River, and in various parts of the coastal districts of New South Wales and Victoria, made very elaborate shields with incised designs representing animals. Their spear-throwers were ornamented in the same way. Very characteristic, indeed, is the incised zig-zag pattern on Western Australian shields and spear-throwers. In some cases concentric squares are cut on weapons and corroboree tablets, and (more especially in New South Wales) trees near a grave are ornamented on one side or all round, for many feet from the ground, with deeply cut designs, some of which may be totemic in significance. Occasionally incised drawings of animals are made on rocks. *Burning* the surface with a fire-stick is not a frequent form of ornamentation, and is only used in the case of 'pointing sticks,' of which, in the central area, it is very characteristic. It takes the form of a series of spiral lines, circles, notches, or dots. *Painting* a surface with pigment is by far the most common method of ornamentation, and is applied to (1) weapons and implements, (2) human bodies, (3) rocks, bark, and the ground. In many tribes it is customary to coat almost every weapon with ochre. Boomerangs, shields, spears, dilly-bags, knives, and fighting clubs may have special designs. Attention may be drawn to the zig-zag designs of Western Australia, to the bold decorative schemes on the large Queensland shields, to the carefully drawn decoration of Queensland dilly-bags (where conventional designs are sometimes associated with zoomorphs), and to the very characteristic and effective designs on spears, throwing-sticks, grave-posts and large bark baskets of the Melville and Bathurst islanders. The latter differ from any on the mainland. The various designs indicate considerable variations in artistic skill, but all show that the native has a distinct feeling for decorative effect. Drawings on human bodies are done

in red and yellow ochre, pipeclay, and charcoal. In some cases the designs are merely what the natives call 'play-about,' but the more important are associated with the performance of corroborees; these, in almost all cases, are purely conventional designs of circles and lines that often follow the contour of the body. Each corroboree has its own design. Drawings on rocks and bark are among the most interesting, and vary much. They may be zoomorphic, phytomorphic, or purely conventional, though the first two are more common than the third. In one (zoomorphic) the spectator is supposed to be looking upwards from beneath an emu that is sitting on its eggs; in others we have drawings of wild dogs, kangaroos, and various animals; in others, of cycad fronds; while others are purely conventional concentric circles of lines and dots. The 'red hand,' about which so much has been written, has no special significance. It is met with everywhere, and is made by placing the hand on a rock or bark surface, and then silhouetting it by means of blowing red ochre on to the surface round it. Sometimes pipeclay or charcoal is used, in which case we get a white or black hand; but in no case—red, white, or black—has it any more significance than the outline of a fern made by a child spraying ink over the frond. In some cases, more especially on the northern coast-line, fairly elaborate drawings of animals and mythical objects are made on rocks or sheets of bark. The walls of rock-shelters are covered over with crude, but often suggestive, representations of the animals the natives feed upon—crocodiles, lizards, snakes, fishes, etc.—sometimes also with quaint drawings of gnomes that inhabit the mangrove swamps and rocky ranges. By far the most elaborate rock paintings, however, are those in the Kimberley district, first described by Sir George Grey. Their origin is a mystery, but it may be regarded as certain that they were not drawn by Australian aboriginals of the race known to us.

Sacred designs are often not distinguishable at first sight from some of those described above; in fact, so far as conventional drawings (such as concentric circles) are concerned, as much depends on the location of the drawing as on its nature. In one spot a drawing will be sacred, in another it will not; but, whilst this is so, yet, on the whole, the sacred designs are well defined. They are best known in the central and northern tribes, amongst whom they are very well developed. In the Arunta, for example, every totem group has its Ilkinia, or totem design, which the men of the totem group may paint on themselves. In addition to this, right through the tribes every separate totemic ceremony involves a special design, painted on the bodies of the performers, consisting of lines of red and white down that often cover closely the whole of the upper half of the body and face, and extend upwards on to an elaborate head-dress. In every instance the down is fixed on the body by blood drawn from the performers. Some totemic groups have in addition special designs drawn on rocks at places where churinga are stored and ceremonies are performed. No women go there. Others have ground drawings of a very elaborate kind, best exemplified by the Wollunqua snake totem in the Warramunga tribe. Two of these drawings will suffice. In one the sandy soil is smoothed down with water to make a firm flat surface, over which a coating of yellow ochre is spread; on this five series of concentric circles are drawn, representing trees and waterholes at the home of the Wollunqua—a sinuous band 18 feet long represents the snake itself, and footmarks by the side indicate those of an old man, its mate. The rest of the design consists of white spots of pipeclay that entirely surround the black bands. In the other a mound, 15 feet long and 18 inches high, is made and covered with dots of pipeclay that surround and outline a sinuous band of red ochre along each side, representing the snake. Ground designs similar in significance, associated with sacred ceremonies, exist (or once did) amongst many tribes on the eastern coast.

Some of the more elaborate designs are found on objects worn or carried by men performing sacred ceremonies. One such special object may be described, partly because it represents one of the most elaborate, partly because the significance of its different constituents gives a good idea of one side of the native mind. It is called 'waninga,' and is (or was) used in tribes round Lake Eyre, such as the Urabunna, and also among the southern Arunta. It is important to note that a waninga used in a kangaroo ceremony, for example, represents a kangaroo, while a similar one used in a rain ceremony represents rain and things associated with it. Take a rain waninga. A strong spear, 10 feet long, forms a central shaft; at right angles to its length, and at a distance of 2 feet from either end, are two sticks, each 3 feet long; between them, running parallel to the length of the spear, lines of human-hair-string are tightly strung. Each line takes a turn round the transverse bar at either end, slants away to the spear, turns round this and runs back to the bar, until the whole space between the bars is filled by close-set bands of string with a triangular-shaped patch at each end. A band, 1½ inches wide, running round about the same distance within the margin, is made of opossum-fur-string, whitened with pipeclay, the same width of string on the inside of it being red ochred. Tufts of the red-barred tail-feathers of the black cockatoo are tied to the tip of the spear and the ends of the bars. A number of bands of white down run in parallel lines across the strings. The man carrying the waninga wears wood-parings on his head, smeared in blood. The red string represents thunder; the white band, lightning; the ordinary black string, rain falling; the white down, clouds. Black cockatoo feathers are used because the call of these birds is always taken as an indication that there is a waterhole near. The red of the feathers and the blood-smeared wood-parings represent the masses of dirty-brown froth that float on flood-waters. This waninga is used during rain-making ceremonies, and serves as a good example not only of decorative art, but of the exercise of sympathetic magic.

W.B.S.

Destiny. In the early days the number of aboriginals diminished through quarrels with the settlers—the whites violating some aboriginal law, the blacks retaliating, or vice versa. For something that from a white man's point of view was a crime a whole tribe would, in official language, be 'dispersed;' and similar methods were employed unofficially. The aboriginal had little protection and no redress; it would have been better for him if he had been an uncompromising fighter, declining to have anything to do with his spoilers. Some scheme might then have been devised whereby his rights would have been recognized, and he would have been kept from contact with our civilization. Such

contact as has occurred, and now obtains, does not tend to absorb the blackfellow or graft him on to our race; it withers or rots him. The half-caste problem threatens to become serious. In early days the tribes sometimes solved the problem by effective, if rough, means such as killing them all. The great difficulty is that the half-caste has no family life, or social place, or legal position with either blacks or whites; he is made to feel this and acts accordingly. Sometimes, no doubt, he has an honourable place among the blacks, or a place of trust among the whites; but this does not often occur. The increase in the number of half-castes is very marked. In South Australia during 1901-8 there was a decrease of 316 blacks and an increase of 125 half-castes. The years 1912-17 show a decrease of 148 full-bloods and an increase of 84 half-castes.

The dying out of the aborigines is due to a number of causes, some fairly well known. Epidemics of smallpox, or a disease indistinguishable from it, have almost annihilated whole tribes. This disease and venereal disease, introduced by the overlanders, was almost the sole cause of the extinction of the Coorong blacks. Venereal disease (which exterminates in another way also, by making the black women sterile) is widespread wherever there is contact with civilized people. Consumption, which is inseparable from the habits of clothing and housing, is responsible for a large number of deaths. It has been remarked that, while many die from our diseases, a great many also die from our medical treatment.

On 21 December 1839 Lord John Russell wrote to Sir G. Gipps:—'You cannot over-rate the solicitude of H.M. Government on the subject of the Aborigines of New Holland. It is impossible to contemplate the condition and the prospects of that unfortunate race without the deepest commiseration . . . . It is impossible that the Government should forget that the original aggression was our own, and that we have never yet performed the sacred duty of making any systematic or considerable attempt to impart to the former occupiers of New South Wales the blessings of Christianity, or the knowledge of the Arts and advantages of civilised life.' Some settlers in South Australia objected to sections of land being appropriated for the aboriginals before the white settlers were allowed to select. Governor Gawler replied:—'The invasion of those ancient rights by survey and land appropriations of any kind, is justifiable on the ground, that we should at the same time reserve for the natives an *ample sufficiency* for *their present* and future use and comfort, under the new style of things into which they are thrown; a state in which we hope they will be led to live in greater comfort, on a small space, than they enjoyed before it occurred, on their extensive original possessions.' On 1 August 1840 the South Australian *Register* in a leading article said: 'We say distinctly and deliberately that nothing comparatively has yet been done—that the natives have hitherto acquired nothing of European civilization, but European vices and diseases, and that the speedy extinction of the whole race is inevitable, save by the introduction of means for their civilization on a scale much more comprehensive and effectual than any yet adopted.' This might be reprinted to-day as a statement of fact applicable to the present position. Apart from some State pittance and a modicum of State supervision, the aboriginal is of little interest to anyone but some benevolent societies and a few very ardent anthropologists.

Before the coming of the white man, the black man's personal and racial needs were few and simple; his implements, intellect and habits were well adapted to supply those needs. While isolated in his primitive condition there was no need for much change, whether such change might be called advancement or not. This appears to be true of primitive peoples since the earliest times in the world's history. But circumstances change when outsiders, coming as invaders or as visitors, make the formerly isolated tribes feel, not satiable needs, but new insatiable wants, and exploit the population or the country, or both, for their own ends.

To one who knows how the blackfellow even in a single lifetime reacts to new influences—moral, intellectual and mechanical—the facts seem to upset all theories of cranial capacities, cerebral functioning and mental operations. They raise the question, indeed, whether ordinary anthropological investigations and tests supply the kind and amount of evidence with which we credit them for elucidating the evolution of races and the relations of peoples. It would appear that civilized man knows as little regarding the possibilities of the mind of his uncivilized brother as he does regarding those primitive savage instincts which he for a long time supposed to be dormant, dead, or never existent in the civilization to which he belongs. W.R.S.

Ramsay Smith's *In Southern Seas* (1924); Herbert Basedow's *The Australian Aboriginal* (1925); and *The Official Year Book of the Commonwealth*, No. 3, pp. 158-176. A fuller list of authorities is given at the end of the article on ABORIGINAL LANGUAGES.

Abrus, a small genus of twining or trailing plants of the family Leguminosae, chiefly tropical. The flowers are pink (rarely white); pod almost square at both ends; seeds brilliant scarlet, with a black blotch; leaves with several pairs of leaflets; the midrib ends in a point. The only indigenous species is *A. precatorius* (Weather-plant), the seeds of which are known as 'crabs' eyes' or 'jequirity beans' and made into necklaces and other decorative ornaments by the Pacific islanders, while Indian jewellers use them as a standard of weight.

Acacia, a genus of plants of the family Leguminosae, represented in the Australian flora by more species than any other. Out of 767 species known to botanists over 500 (as well as a number of forms) are indigenous to Australia. Akin to the mimosas of America, and themselves often known as mimosas in Europe, the Australian species are called 'wattles,' because their long pliant twigs were used by the early settlers in the construction of 'wattle-and-dab' huts (see CALLICOMA). The prevalence of the genus throughout the continent, characterized almost everywhere by profuse blooms, delicate in colour and scent, has made the wattle the national emblem; a literature and a sentiment have grown up round it, and 'Wattle Day' (q.v.) is an established anniversary in many centres of population. On the inland plains the generic name 'wattle' is

frequently superseded by aboriginal or vernacular names attached to particular species—e.g. Myall, Mulga, Dead Finish (*A. tetragonophylla*), Needle-bush (*A. rigens*).

The genus is divided into two principal groups, according to the arrangement of the flowers; in one group the inflorescence consists of a number of diminutive flowers in globular clusters, in the other of short golden spikes. A further grouping depends on the structure of the foliage; one section—of which the Green Wattle (*A. decurrens*) is an example—has

Green Wattle.

feathery (pinnate) leaves, whereas in the other section the axis of the leaf broadens into a leaf-like organ known as a phyllode, which performs the functions of an ordinary leaf. In all acacias the seedling leaves are feathery, any change to phyllodes occurring in the adult stage. The species vary considerably in size, from prostrate or matted forms a few inches high to shrubs and small trees; a few species attain a dignity of forest trees. Many flower in the early spring, and are very suitable as ornamental shrubs for parks and gardens, since their bright blooms—which range in colour from almost pure white to deep yellow—appear when but few other plants are in flower. They are not, as a rule, suitable for street-planting, being short-lived and exceptionally subject to the attacks of boring insects. Cutting the flowering twigs is not injurious to the plants—indeed, in most cases judicious pruning is beneficial—but roughly tearing them off injures the tissues, and prepares the way for disease and insect attack. Their cultivation is not difficult, though the hard nature of the seed-coat makes it necessary to assist germination by putting the seeds in water that has just boiled, and leaving them there until it is cold. Under natural conditions germination is hastened by bush-fires, after which the seedlings spring up in great abundance—a method often artificially applied in nurseries and plantations. The acacias are valuable agents in soil fertilization, as they have—in common with many legumes—the power of assimilating nitrogen by the activities of bacteria located in tubercles formed on their roots. They also yield a considerable amount of honey at a time when other flowers are scarce. Several species are stripped for their bark, which is in great demand for tanning. The species most valued for this purpose are the series grouped under *A. decurrens* (Green or Black Wattle of New South Wales), and the South Australian Golden Wattle (*A. pycnantha*); the latter is considered one of the best tan-barks in the world. Among other species that are stripped for their bark *A. falciformis* (Mountain Hickory), *A. binervata* (Two-veined Hickory) and *A. leiophylla* (Weeping Wattle of Western Australia) are prominent. The bark of all acacias is more or less astringent, and is used in domestic medicine as a decoction or infusion in cases of diarrhoea, dysentery, etc. Other useful products obtained from acacias are timber and gum. The gum is usually of a dark yellow or reddish-brown colour, and is generally found in large tears or masses. That obtained from species growing in arid districts is usually soluble in water, and makes an excellent mucilage; but it is not formed in large quantities, and is therefore commercially unimportant. The Mulga (*A. aneura*) of the western plains grows in dense thickets, the so-called mulga scrubs. Its leaves are relished by stock—in times of drought, indeed, sheep have subsisted wholly upon this diet. The shrubs are beset with two kinds of galls, one astringent and unpalatable, the other edible, large and succulent. The latter, known as 'mulga apples,' are very welcome to thirsty travellers in the arid interior. The excessively hard, dark-brown wood is used by the aborigines for boomerangs, nulla-nullas, shafts of spears, and sticks wherewith to dig up edible roots. This species ranges through the interior from E. to W. The Weeping Myall (*A. pendula*) is a useful fodder tree, sheep being very fond of the leaves, and in time of drought is an excellent stand-by; in many districts hungry sheep have exterminated it by eating down the seedlings, but horses are said not to relish it. The wood is hard, of a rich, dark colour, and beautifully marked. While unpolished it has a peculiar violet-like fragrance, a property which has brought it into request for making glove and handkerchief boxes. The aborigines make boomerangs of it. The species is found chiefly in the interior, and is regarded as an indication of good soil. The Green or Black Wattle (*A. decurrens*) is represented by several very distinct varieties, differing considerably in morphological characters and flowering seasons, but all highly ornamental trees. The Ironwood (*A. excelsa*) is the largest and most conspicuous species on the western plains, attaining a height of 50-60 feet, with a trunk-diameter of three feet. The timber is hard, interlocked, deep red in colour, with a beautiful figure. It is used for mining purposes where great strength is required; it also resists the action of sulphur in copper mines. When young, the stem is covered with spreading branches, but the mature tree has a clean trunk. This protective character in the young growth is characteristic of many western trees (see FLIN-

DERSIA). The Brigalow (*A. harpophylla*) a small tree, forms almost impenetrable forests in the interior (especially on the inland downs country in Queensland) known as 'brigalow scrubs.' The scimitar-shaped phyllodes have a characteristic blue-grey sheen.

The Blackwood (*A. melanoxylon*) is so called from the black colour of the mature wood, which is hard and close-grained and is classed with walnut for furniture-making. It is also used by billiard-table-makers and coachbuilders. Charcoal made from it burns with an intense heat. The best blackwood timber comes from Tasmania, where the trees reach a height of 60-70 feet. The species is chiefly eastern, extending from South Australia to Queensland. *A. Baileyana* (Cootamundra Wattle) is probably the most decorative species of the genus, and is most frequently cultivated as an ornamental

Long-leaved Golden Wattle (*A. longifolia*).

tree. Exclusively confined to New South Wales, it was described by Baron von Mueller, who named it in honour of the late F. M. Bailey (q.v.). *A. homalophylla* (Yarran), an inland species, has a dark-brown wood, valued for turnery on account of its solidity and fragrance. It has been extensively used in the manufacture of tobacco-pipes. *A. Cambagei* (Gidgee or Stinking Wattle) is frequently confused with yarran, from which it may be readily distinguished by the offensive odour of its foliage. It has a very durable timber, much used for fencing-posts. The wood is frequently marked with handsome parallel lines, caused by the uniform wavy grain; it is then known as ringed gidgee, and is much prized for making ornamental walking-sticks and stock-whip handles. The Native Willow (*A. salicina*) ranges across the inland areas of the continent. In the dry west it is a valuable fodder plant. The timber is tough and heavy, dark-brown and nicely marked. The aborigines make boomerangs of it; settlers use it for furniture. *A. Sophorae*, the Spreading Coast Wattle, ranges along the southern seacoasts and extends to Tasmania. The bark of this shrub has been used by fishermen, with a measure of success, to tan sails and nets. The aborigines of Tasmania used to roast the ripening pods and eat the seeds. It is useful as a coastal sand-binder.

A. rubida (Red-leaved Wattle) is an ornamental shrub with leaves frequently reddish-brown. In this species the young (feathery) foliage continues until the plants reach a height of several feet, when the adult foliage (phyllodia) appears. *A. implexa* (Hickory) is a medium-sized tree, found chiefly in the eastern coast-districts. Its foliage is eaten by stock. The wood is hard, dark-brown, with yellowish stripes, and is used for cog-wheels and other turnery in which strength and tenacity are required. *A. decora* (Western Silver Wattle) is a shrub found on the western plains of New South Wales. As the specific name implies, it is a highly ornamental plant. *A. Bakeri* is one of the largest of the acacias. A specimen on the mountains near Murwillumbah in New South Wales was 160 feet in height, with a diameter of two to four feet, and a trunk clear of limbs up to a height of 50-60 feet. The Currawang (*A. doratoxylon*), a shrub found chiefly on stony ridges in dry country, is of some service as food for stock in times of drought. *A. glaucescens* (Coast Myall), is a highly ornamental tree, with handsome flower-spikes and ashy-green pendulous foliage. *A. pycnantha* (Golden Wattle), is extensively cultivated as an ornamental tree, as well as for its valuable bark. It is most plentiful in South Australia, but extends through Victoria into New South Wales.

A. elata, the Cedar or Pepper-tree Wattle, is an ornamental tree resembling the well-known exotic Pepper-tree (*Schinus molle*). It is confined to elevated districts in New South Wales. *A. aulacocarpa* (Brush Ironbark) has a hard, durable timber. It is a central and northern species, known as 'dilka' by the Port Curtis blacks. *A. binervata* (Two-veined Hickory), an eastern coastal species, has a close-grained wood suitable for axe-handles, bullock-yokes, etc. It reaches a height of 30-40 feet. *A. Cunninghamii* (Bastard Myall) is a small tree, widely diffused. The timber takes a good polish, is dark in colour, and is useful for cabinet purposes; it resembles red cedar, but is much heavier. *A. Bidwilli* is the 'waneu' of the central Queensland blacks, who bake and eat the roots. The seeds of *A. cibaria* were eaten by the natives of Shark Bay. The timber of *A. acuminata*, a Western Australian species, has an odour resembling that of raspberries, which gives it the popular name of Raspberry-jam Wattle. *A. armata* (Kangaroo Thorn) is a prickly shrub, occasionally grown as a hedge.

See von Mueller's *Iconography of Australian Acacias, Key to the System of Victorian Plants*, and *Second Systematic Census of Australian Plants;* Bentham and Mueller's *Flora Australiensis;* Maiden's *Forest Flora of New South Wales, Wattles and Wattle Barks, Useful Plants in Australia*, and papers in the *Journal and Proceedings* of the Royal Society of New South Wales; Bailey's *Comprehensive Catalogue of Queensland Plants;* and Cambage's *Acacia Seedlings* in *Journal and Proceedings* of the Royal Society of New South Wales.

Acaena, a genus of plants of the family Rosaceae, dispersed over the temperate and cooler

regions of the southern hemisphere, and especially abundant in South America. Three species are indigenous to Australia, of which one (*A. montana*, a native of Tasmania) is probably peculiar to the country; the other two are also found in New Zealand and one of them in South America. The calyx-tube is bell-shaped; petals obsolete; stamens 2-10; fruit a dry carpel, enclosed in the hardened calyx-tube, which is usually closed at the top and more or less awned with spines or barbed bristles. *A. sanguisorbae* (known as Biddy-biddy Burr in Australia, Native Agrimony in Tasmania, and Piripiri in New Zealand) has numerous flowers in dense globular heads on long stalks; the fruiting calyces are 4-angled, with a barbed spine on the apex of each angle, the whole forming a large spiny burr. It is disliked by pastoralists, as the burrs are very tenacious, and their presence in wool lowers its value considerably. In *A. ovina* the flowers are arranged in clusters along an elongated flower-stem.

Acarina, an order of Arachnida (q.v.) comprising the mites and ticks. It is of great economic importance, as its members are chiefly (though not wholly) parasitic on mammals—including man—birds, reptiles, fishes, molluscs, insects and plants. In Australia 22 families—about 69 genera and 165 species—are known, but many (e.g. the cheese-mite) have been introduced with trade. Of the indigenous species little is known. A few have received names and have been described, for the most part very superficially. There is probably no section of the Australian fauna that offers such an extensive field for investigation, and yet has been so neglected. Some non-parasitic mites have developed a remarkable nymphal form (*hypopus*), which has a number of sucking disks on the ventral surface; these enable it to attach itself temporarily to some insect (spider, beetle, fly or butterfly) to be carried into a locality that suits it. Extreme cold or moisture has little effect upon mites. Many are the cause of loathsome diseases in man and the lower animals; e.g. *Sarcoptes*, which is responsible for itch in man and mange in horses, dogs, and cats, and the mites which produce erythema and 'grocer's itch.' To gardeners Red Spider (*Tetranychus bimaculatus*) is a well-known foliage pest, and a species of *Bryobia*, known as 'red mite,' attacks apple and pear trees in Australia. A eupodid mite related to the 'red spider' has of late years attacked oat crops in New South Wales, resting on the flag and sucking out the sap with its beak. It has a rounded beak, blue body, and legs of a brilliant red. The Root-mite (*Rhizoglyphus*) is a destructive cosmopolitan enemy to tubers and legumes, both in store and in the soil. All mites have eight legs in the adult stage, except the Eriophyidae, which have four. To this family belongs the world-wide *Eriophyes pyri*, which produce galls on the leaves of pear-trees, while allied species attack leaves and stems of other trees. The life of an acarid has four stages: egg, larva, nymph and adult. The majority are oviparous, a few are vivi- or ovo-viviparous, while *Pediculoides* is said to bring forth adults. *P. alastoris* occurs near Sydney.

Ticks affect cattle and sheep (see CATTLE-TICK, SHEEP-TICK), dogs, birds, and sometimes man. If one is picked up, it must on no account be forcibly removed, or the embedded barbed beak will break off and produce serious effects. A safe remedy is to smother the tick with oil (kerosene will do), when it will immediately back out. Bushmen sometimes apply nicotine from their pipes.

Acarids have few natural enemies beyond their predatory relatives, but there are cases of protective resemblance, especially among immature forms.

See Rainbow's 'Synopsis of Australian Acarina' in *Records of the Australian Museum*, vol. vi.

W.J.R.

Aciphylla, an alpine genus of plants of the family Umbelliferae, which occurs in Australia, New Zealand and the Antarctic islands. The calyx-teeth are prominent; petals often inflexed at apex; carpels dorsally compressed, usually with 5 acute prominent ribs. The leaves have broad sheathing bases. All the species are perennial herbs, with flowers in numerous umbels, each surrounded by an involucre of narrow bracts. *A. glacialis* (Mountain Celery), a robust plant, forms tufts in grasslands on the Australian Alps above 5000 feet, and bears a profusion of white, scented flowers. The sheathing bases of the divided leaves are marked with transverse lines and longitudinal striations. The tap-root is exceptionally long. *A. simplicifolia* has simple undivided, long, and narrow leaves.

Ackama, a genus of plants of the family Cunoniaceae, has two species, one endemic, the other occurring also in New Zealand. The calyx-tube is short, bell-shaped, 5-lobed; petals 5; stamens 10, inserted round a crinkle-edged disk; fruit-capsule small, turgid; seeds few, oval, hairy. The trees have opposite leaves, usually divided into 5 leaflets. *A. Muelleri*, a 'cork-wood,' is an eastern species with a soft, feathery inflorescence, and well deserves cultivation; in favourable circumstances it becomes a large tree. It has a tough, close-grained timber, with a purplish cast when fresh, which dresses well. Pouched structures known as domatia (q.v.) occur on the under-sides of the leaves.

Actinotus, a genus of plants of the family Umbelliferae, is endemic in Australia. The calyx-limb is truncate or 5-lobed; petals (when present) 5, rounded and concave; fruit oval, crowned by the persistent calyx-limb, compressed, 5-ribbed, without oil receptacles. The species are herbs, annual or perennial, and have flowers in compact umbels, surrounded by an involucre or herbaceous bracts. *A. Helianthi* is the Flannel Flower (q.v.) of New South Wales.

Adams, FRANCIS WILLIAM LAUDERDALE (1862-1893), son of Professor Andrew Leith Adams, F.R.S., F.G.S., was born at Malta on 27 September 1862, and educated first at a private school in Shrewsbury, and afterwards in Paris. After spending two years as assistant master at Ventnor College, he in 1882 migrated to Australia. In 1884 he published *Henry and other Poems* (London), and in 1885 *Leicester, an Autobiography*, which was followed in 1886 by *Australian Essays* (Melbourne), *Madeline Brown's Murder* (Sydney), and *Poetical Works* (Brisbane). In 1888 there appeared in Sydney *Songs of the Army of the Night*, which afterwards went through three editions in London. During his residence in Sydney he was regularly employed on the staff of the *Bulletin*. He left Australia in 1889, and in 1891 published in London *John Webb's End*, and contributed Australian sketches to the *Fortnightly Review*. After two years' stay in England (during which he published *The Melbournians*) he spent the winter of 1892-3 in Alexandria, struggling in spite of an incurable lung-disease to finish a book attacking the British

occupation of Egypt. During the summer of 1893 he went to live at Margate, England, where in a fit of depression he died by his own hand on 4 September 1893. *Australian Life* and *The New Egypt* appeared in 1893, the latter after his death; *Tiberius* (a drama) and *A Child of the Age* in 1894, and *Essays on Modernity* in 1899. Apart from the excellent and mature *Tiberius*, his literary work lacks restraint, and is interesting chiefly as a promise of what in riper years he might have achieved.

Adansonia, a genus of plants of the family Malvaceae, consisting of two species. *A. Gregorii* (Sour Gourd or Cream of Tartar Tree)—an endemic species confined to northern Australia—is hardly distinguishable from the exotic *A. digitata*, the well-known Baobab tree of South Africa. It is a large tree with a girth out of proportion to its height; some specimens attain a circumference of 80 feet at 2 feet from the ground. It grows on sandy plains and low stony ridges from the Glenelg River to Arnhem's Land, rarely above 100 miles inland. The huge trunk acts as a storage reservoir of food and moisture. The fruit, which resembles a small gourd, is about 6 feet long and 3-4 inches in diameter; its dry, acidulous pulp has an agreeable taste, and is peculiarly refreshing in the sultry climates of its habitat. It consists of gum, starch, sugary matter, and malic acid, and is said to taste like cream of tartar.

Adelaide, capital of the State of South Australia, lies in latitude 34° 55′ 38″ S., longitude 138° 35′ 04″ E., on the river Torrens, a few miles inland on the eastern side of the Gulf of St. Vincent. The site of the city was not decided on without many quarrels among the earlier colonists of South Australia. The first settlers (who arrived in July 1836 by the *Duke of York* and the *Lady Mary Pelham*) were landed at Nepean Bay on Kangaroo Island; but when Colonel Light, the surveyor-general, arrived in the following August, he made a temporary settlement at Holdfast Bay (Glenelg) on the mainland. After some delay and further explorations a safe and convenient harbour (called Port Adelaide) was discovered in the Gulf of St. Vincent; and Colonel Light selected a tract of rising land seven miles inland, on a stream afterwards called the Torrens River, as a site for the new colony's capital city. It was named Adelaide at the request of King William IV, in honour of his queen. The choice of the site soon caused considerable dispute; Governor Hindmarsh, among others, objected to it on the ground of its remoteness from the harbour, and wanted a site seven miles lower down the river, while expressing a preference for Encounter Bay. But the colonization commissioners in England, when appealed to, declared that Colonel Light's authority in the matter was absolute, and a majority of the colonists backed him. Experience has demonstrated the wisdom of his choice, and similar wisdom was exercised in laying out the city, which was made square in form, with ample provision for wide streets, public squares and park-lands surrounding all. In March 1837 the plan of the town was exhibited; 1042 acre-lots were marked out. 437 preliminary claims were satisfied (those who had contributed to the first fund raised for establishing the colony being allowed to choose their lots), and on 27 March 567 other lots were sold by auction at prices ranging from two to fourteen guineas. The total sales-money amounted to £3594.

The first houses were built of limestone, brick, *pisé*, and mud. A few wooden cottages also had been imported. The governor's house was of mud between laths, supported by uprights of native wood, and covered thickly with thatch; fire-places were forgotten in the plan, and a fire-place and chimney were afterwards built close to the front door. The architect was a sailor, and the workmen seamen from H.M.S. *Buffalo*. A depot for immigrants had been formed at 'Emigration Square.' This was originally called 'Forbes Square;' it was on the West Park-lands, not far from where the observatory now stands, and was not considered a very desirable situation.

The first newspaper published in South Australia was issued by Robert Thomas, who arrived in the *Africaine* in November 1836, brought a printing-press with him, and printed his paper in a rush hut at Holdfast Bay until the site for the city was fixed. The plant was then removed to a 'town acre' in Hindley-street, a little west of Morphett-street. The newspaper, the *South Australian Gazette and Colonial Register*, had been first published in London under that title on 18 June 1836, prior to the departure of the first band of settlers; the second number was published in South Australia on 3 June 1837 (and reprinted as a supplement to the *South Australian Register* of 2 December 1878). In 1858 a rival newspaper, the *South Australian Advertiser*, was established. Both newspapers, issued daily, still continue. The first Adelaide schoolmaster, John Banks Shepherdson (who was sent out by the South Australian School Society, and arrived a few months after the colony was founded), opened his school in a wooden building on the Park-lands, opposite where Trinity Church now stands.

In August 1840 a municipal corporation was created for Adelaide—the first in Australia; voters must have lived in the colony for six months and own city property rated at not less than £20. For the first election of councillors and aldermen polling-booths were erected at the intersection of King William and Hindley streets. James Hurtle Fisher headed the poll for councillors and was chosen mayor, a position that he occupied five times. A railway from Adelaide to Port Adelaide (7½ miles) was opened on 21 April 1856; it was extended to the Semaphore (1¾ miles farther) in January 1878. A new bridge, costing over £22,000, was built over the Torrens in 1856. The following year the park-lands were fenced in, and a portion planted. The exhibition building was erected and used for the first time for the February show in 1860. In 1839 the first botanic gardens were laid out by public subscription, not far from the old bridge called the 'Company's bridge,' that spanned the Torrens. The experiment apparently did not prosper, as in 1840 the gardens had been abandoned and were going to ruin. In 1854 the legislative council voted a sum of £3000 for the purpose of establishing a public botanic garden under government control, and on 10 March 1855 the present site was chosen. G. W. Francis, the first director, planned and laid out the garden. There is a cenotaph to his memory near the entrance. The university of Adelaide (see UNIVERSITIES), incorporated by act of parliament passed in 1874, was opened in April 1882, and the Elder Conservatorium of Music in 1898.

In June 1878 a system of horse-tramways was instituted by several private companies, and continued until 1906, when a municipal tramways

trust act empowered the South Australian government to acquire the lines with a view to their electrification. In 1907 a trust of eight members (two nominated by the governor, two elected by the city corporation, and two each by the suburban corporations and the district councils was formed, and 49 miles of horse-tramways were purchased at a cost of £280,372. The electric system was inaugurated on the Kensington route on 10 March 1909. On 31 July 1921, 62½ route miles had been electrified and opened for traffic; the corresponding length of track opened was 107 miles. The power-house is located on the river at Port Adelaide, nine miles from the city.

The water supply for Adelaide and suburbs is obtained from catchment areas of the rivers Onkaparinga, Torrens, and Sixth Creek, and from springs. Storage reservoirs have been constructed at Thorndon Park, Hope Valley, Happy Valley, and Millbrook; their total cost to 30 June 1924 was £3,100,856, and their storage capacity was 7,748,070,000 gallons, by which an ample supply of good water was available throughout the year. The length of mains laid in the metropolitan area is about 1076 miles, varying in size from 2 to 48 inches in diameter.

At the last census (4 April 1921) the population of Adelaide was 255,481 persons, of whom 134,711 (over 52 per cent) were females. In December 1924 the population was estimated at 278,856.

See SOUTH AUSTRALIA and books named there.

Adenanthera, a small genus of plants of the family Leguminosae, is tropical in habitat, with several Australian species. In the best-known of these, *A. pavonina,* the leaves are mimosa-like; flowers small, white or yellowish, in long, narrow spikes; pod narrow, curved, with more or less complete partitions between the seeds; seeds with a hard, shining red (or red and black) coat, about the size of a kidney-bean. The seeds are strung into necklaces and other articles of personal adornment.

Adenanthos, a genus of tropical plants of the family Proteaceae, occurring chiefly in extra-tropical Western Australia; *A. terminalis,* however, is found in South Australia and the Wimmera district of Victoria. The flowers are red or greenish, enclosed within a series of bracts (usually 6) forming an involucre; corolla-tube split more or less on the lower side, and usually falls off entire, leaving a very short ring-like base; style usually arched, protruding from the slit of the tube; fruit a small oblong nut; leaves entire or divided, often small and crowded, rarely rigid and prickly-pointed. The species are shrubs or small trees, erect or prostrate.

Agnew, SIR JAMES WILSON (1815-1901), born at Ballyclare in Ireland on 2 October 1815, and educated for the medical profession (M.R.C.S., Lond., 1838; M.D., Glasgow, 1839), migrated in 1839 to New South Wales, and after a short stay in western Victoria settled in Hobart in 1841. Here he practised his profession for 36 years, occasionally combining with it minor medical posts under the government. In 1877 he abandoned medicine for politics, was elected by Hobart to the legislative council, joined the Fysh-Giblin ministry (1877-8), and was for a short time a member of the second Giblin ministry (1879-81), being on both occasions minister without portfolio. After a visit to England he took over from Adye Douglas in 1886 the ministry which the latter had formed in 1884, but resigned in March 1887, and abandoned politics. He died at Hobart on 8 November 1901.

Agnew's real service to Tasmania had little to do with politics. From his arrival in 1841 he was prominent in scientific studies and in the encouragement of art; he helped to found the Royal Society of Tasmania, contributed valuable papers to its journal, joined the council in 1851, and became secretary in 1860; he was chairman of the boards that administered the public library and the museum, a member of the council of education, and for a short time a member of the council of the university. And his personal influence in Hobart, always exercised for good, was unique, making him a greater citizen than many who were more officially prominent. (K.C.M.G., 1894.)

Agricultural Education. In the year 1885 two agricultural colleges were founded in Australia, one at Roseworthy in South Australia, the other at Dookie in Victoria.

Roseworthy College opened with 15 students, and the attendance has steadily increased up to 66. In 1905 it was formally affiliated with the university of Adelaide, and candidates for the B.Sc. degree in agriculture have to spend two years at the college. It has about 2000 acres of land, on which the college buildings stand; about one hundred acres are under vines and fruit-trees, and the balance is divided between experimental work, general farming and live-stock raising. The college is under the immediate control of the department of agriculture.

Dookie College, on the fringe of the Goulburn valley between Shepparton and Benalla, has an area of 5920 acres; another college has been built at Longerenong in the Wimmera, eight miles from Horsham, with an attached farm of 2386 acres. Each college has over 1000 acres under cultivation. The revenue from 155,480 acres of Crown lands is set apart for the upkeep of these colleges, which are controlled by a council of agricultural education, consisting of 11 members, five being nominated by the governor-in-council and five elected by the agricultural societies of the State. The director of the department of agriculture is *ex officio* a member of the council, and its treasurer. Dookie has accommodation for 120 resident pupils, Longerenong for 60. Approximately 2000 students have passed through these colleges.

In 1888 the government of New South Wales founded a department of agriculture and established a complete system of government farm schools, apprentice schools, experiment farms and demonstration farms throughout the State, with an agricultural college at Richmond on the Hawkesbury River, 38 miles from Sydney. This college is the largest in the Commonwealth. Accommodation is provided for 200 resident pupils, each student having a separate room. All the buildings are lighted by electricity. The farm has an area of 3440 acres of land, about 1000 acres of which are under cultivation. At an attached farm on the banks of the Hawkesbury, comprising 116 acres of rich alluvial soil, a complete system of irrigation is carried out, in order to train students intending to take up areas on the State irrigation settlements.

The Queensland government in 1897 founded a college at Gatton on the main southern line, 55 miles from Brisbane, with accommodation for 60 resident pupils. In 1924 this was reorganized as the Queensland Agricultural High School and College, and placed under the de-

partment of public instruction, which feeds it from the State's 'rural schools.' Boys are admitted at the age of 14 (some join even earlier); there are two courses, a junior and a senior, of three years each, and in the sixth year students specialize either in agriculture or in dairying. At the apex of the system is the university course in agriculture. The college farm comprises 1692 acres, of which 700 are under cultivation. Particular attention is paid to dairying, and to the building up of pure-bred herds of Jerseys and Illawarra shorthorns.

Western Australia possesses an agricultural college, situated at Narrogin on the great southern line, 162 miles from Perth, which provides a two years' course for 25 resident students from 14 to 18 years of age.

All the principal agricultural colleges aim at training men who will adopt farming as an avocation, and their curriculum is devised to fit students for farming of all kinds—mixed, irrigation, dairy, wheat, pig and poultry—or for work in orchards, vineyards and apiaries. Students are also prepared as technical teachers, dairy-factory managers, butter-makers, cheesemakers, milk-testers and inspectors.

Practical training and experience are given in every phase of farm practice, including the handling of live-stock; and on the attached experimental farms are tested the comparative values of fertilizers, systems of crop-rotation, methods of soil-culture, new plants, and the commercial values of various crops. The growth of pure seed, the selection of new varieties and types, the control and suppression of disease in plants and animals, all have attention; and in the college laboratories provision is made for teaching chemistry, economic botany, zoology, soil physics, bacteriology, mechanics and farm engineering, veterinary science and practice, mathematical surveying and levelling, entomology, vegetable pathology, forestry and farm book-keeping. In addition, each student has to become familiar with tools and phases of work not considered essential in more densely populated countries. Many settlers are beyond the reach of tradesmen and repair-shops: agricultural students therefore receive practical training in blacksmithing, carpentry, butchering, and the work of wheelwrights and saddlers. Gardening is not neglected, and the usual social and athletic adjuncts of college life are well provided for. Winter schools lasting four weeks are provided at the slack period of the year for busy farmers and stock-owners, who can devote only a limited time to study and intensive practical instruction. Farmers select the branches of training best suited to their own farms and districts, and often bring to the colleges for solution local problems of cultivation or troubles with live-stock. The departments of agriculture and education in each State collaborate with the State university in all matters relating to specific training in nature study, agriculture and allied subjects; this, at all schools and colleges which the State can influence, is so devised that a student's training may proceed regularly towards the university's Bachelor of Science degree in agriculture. Nature-study, elementary agriculture, and school gardens are being steadily introduced in state primary schools as portion of the curriculum. Agricultural high schools in country centres train lads up to 16 years of age; successful students proceed to the agricultural colleges to complete their training.

Courses established in the universities of Adelaide, Melbourne and Sydney provide special training for the higher branches of agriculture. Students who have shown peculiar aptitude in the high schools and agricultural colleges are offered scholarships and bursaries. The chairs of agriculture at these universities have already demonstrated their value; they have made available specialists competent to deal with insect pests, who are making their influence felt in research work. Of late years farmers are individually visited and influenced by inspectors (or rather instructors) from the agricultural departments, who conduct actual experiments on practical lines in each district to demonstrate the best classes of fodders, etc., to grow, and endeavour to collect local data and ensure a more economic application of type and method on the farms. They also organize, assist and stimulate the formation of agricultural bureaux for instructional purposes. This system of grouping farmers for instruction is becoming very popular, and has resulted in special exhibits at local agricultural shows of district collections of produce staged by members of the bureaux. The Royal Agricultural Society of New South Wales also does its best to develop agricultural education; it makes provision at the annual shows for lectures and demonstrations to students, thus giving object-lessons in the form of the best stock and produce the country can provide. At each show, too, popular lectures are given to farmers. A number of agricultural societies devote part of their income to prizes, scholarships and exhibitions for deserving and competent students, to enable them to pursue courses of training in agricultural and veterinary science at the universities and agricultural colleges. Furthermore, the public library at Sydney includes a large collection of modern books relating to every phase of rural occupation. A special catalogue is issued, from which enquirers may select books applicable to their wants, and these books are sent free on loan to every part of the State.

H.W.P.

Agriculture is one of the three most important sources of Australian wealth—less so than the manufacturing industry, but practically on a level with the pastoral industry. On the figures for the last four years (1919-23) the value of Australian manufactured products has averaged £115,000,000 a year, that of agricultural products £87,769,000 and that of pastoral products £87,133,000—roughly speaking, 30 per cent, 22½ per cent, and 22¼ per cent of the total production-value. Details of the principal crops and of any local methods used in growing them will be found under their names; this article deals with (*a*) the history of the progress of agriculture in the various colonies, and (*b*) information about growing, marketing, government assistance, etc., that are applicable to all or most crops.

Historical Sketch. New South Wales.—Among the 'Instructions for our trusty and well-beloved Arthur Phillip, Esq.' issued to the first governor of New South Wales on 25 April 1787 was one ordering him immediately upon landing to proceed to the cultivation of the land, and another that he should with all convenient speed report on the actual state and quality of the soil at and near the settlement and the probable and most effectual means of improving and cultivating it. A good deal of 'corn and other seed-grain' was shipped in the First Fleet, but Phillip was authorized to obtain more at any port on his route: so at Rio de Janeiro he procured coffee (both seed and plant), coco in the nut, cotton-seed, banana-plants, oranges (seed and

plant), lemons (seed and plant), guava (seed), tamarinds, prickly pear (plant, with cochineal on it), eugenia or pomme-rose, ipecacuanha, and jalap. To this collection he added at the Cape of Good Hope plants of fig, bamboo, Spanish reed, sugar-cane, vines, quince, apple, pear, strawberry, oak, and myrtle. When the expedition reached Port Jackson these were set in plots on the east side of Sydney Cove, near the house erected for the governor. At the head of the next bay eastwards (now Farm Cove) a small area of land was cleared for a farm; this land now forms part of the Sydney botanic gardens. Among the 1030 persons then landed there was only one farmer. One or two others understood a little about farming; but the need for gardeners, and for men capable of supervising agricultural work—in an unknown country, on inferior soil, with a capricious climate, and many unexpected obstacles to contend with—was repeatedly and pathetically urged by Phillip. Difficulties accumulated. 'Most of the axes' wrote Phillip, 'spades and shovels the worst that ever were seen. . . . . Of the seeds and corn sent from England part has been destroyed by the weevil; the rest is in good order.'

Finding it useless to attempt farming on the sandstone soil about Sydney, Phillip discovered a more promising locality 'near the head of the harbour,' which he named Rose Hill (afterwards Parramatta). About May 1790 all attempts to raise a sufficient supply of food failed, and the colonists were reduced to a condition of semi-starvation, when the arrival of several supply-ships afforded timely relief; but the lesson was learned. 'Vigorous measures' wrote Tench, 'were adopted to give prosperity to the Settlement. Large tracts of land were ordered to be cleared at Rosehill and prepared for cultivation. The plough has never yet been used here; all the ground is hard and very imperfectly turned up. Each convict labourer was obliged to hoe sixteen rods a day, so that in some places the earth was just scratched over.' With such imperfect preparation of the soil it seems remarkable that any crops were obtained; but in December 1790 300 bushels of wheat and 60 bushels of barley were harvested, as well as small quantities of flax, maize, and oats, which were preserved for seed. In a despatch dated 17 June 1790 Phillip reported: 'In order to know in what time a man might be able to cultivate a sufficient quantity of ground to support himself, I last November ordered a hut to be built in a good situation, an acre of ground to be cleared, and, once turned up, it was put into the possession of a very industrious convict, who was told if he behaved well he should have thirty acres.' This grant, the first issued in Australia, was made to James Ruse (q.v.) on 22 February 1790. The land is described as 'Experiment Farm;' the cottage to which a portion of it is still attached is to-day known as 'Experiment Cottage.' Ruse's grant was confirmed by the British authorities on 30 March 1791.

The success of Ruse acted as an incentive to cultivation. Phillip offered free grants of 100 acres to non-commissioned officers and 50 acres to privates, while others were encouraged to settle. At the end of the year there were 950 acres cleared and cultivated about Sydney and Rose Hill. In March 1791 Phillip was able to write that 'the settlement is so fully established that the great labour may be said to be passed: . . . though it is not independent for the necessaries of life;' and by the end of that year 30 emancipists and three men still under sentence had been settled on blocks of 30 to 50 acres, some at Subiaco and Carlingford, others on and north of Prospect Hill. In 1792 good soil was found still farther north, about three miles NW. of Parramatta, and a new settlement was formed there, to which Phillip gave 'the name of Toon-gah-be, a name by which the natives distinguish the spot. . . . The quantity of ground in cultivation by the settlers is 416 acres, and they have 97 acres more ground cleared of timber.' At this place there was a government farm, and later on a stockyard for government cattle was built. The same year Phillip reported that 'Our last year's crop of maize, notwithstanding the long drought, was 4,844½ bushels, of which 2,649½ bushels have been issued as bread for the colony, 695 bushels reserved for seed and other purposes, and not less than 1,500 bushels were stolen from the grounds.' But in 1802 King declared that 'the extent of ground about Toongabbee designed by Governor Phillip for public cultivation has been mostly granted away to settlers, leaving Government a very circumscribed space not containing more than 300 acres of entirely worn-out land, which has been in constant cultivation.' In October 1793 Grose reported that 'there is but little doubt of our reaping as much corn this harvest in the colony as will supply us the ensuing year.' The most fertile locality was Prospect Hill, where 'some grounds returned 30 bushels of wheat for one bushel of seed.' By this time two new settlements had come into existence—the Eastern Farms, in the Ryde district east of Carlingford, and Liberty Plains, about halfway between Sydney and Parramatta. The latter settlement, originally peopled by free settlers who reached Sydney in the transport *Bellona* on 15 January 1793, lay in the area now occupied by the modern suburbs of Strathfield and Homebush and adjoined Concord, which was allotted mainly to non-commissioned officers of the New South Wales Corps; the use of the name 'Liberty Plains' to denote the Bankstown district, some miles to the south, is of later date.

In January 1794 Grose initiated the Hawkesbury settlement, under the name 'Mulgrave Place,' in a district examined and approved by Phillip in 1790. Williams, Ruse, and others were permitted to open ground on the banks of the Hawkesbury; Ruse's new farm was situated at the junction of South Creek with the Hawkesbury. The alluvial soil of that district was found to be extremely fertile, and altogether different from any previously cultivated. Grose reports the first settlers' opinions thus: 'I have settled on the banks of the Hawkesbury twenty-two settlers, who seem very much pleased with their farms. They describe the soil as particularly rich, and they inform me whatever they have planted has grown in the greatest luxuriance.' John Macarthur's farm at Parramatta (which joined Ruse's) contained nearly 250 acres, of which, wrote the owner towards the end of the year, 'upwards of 100 are under cultivation, and the greater part of the remainder is cleared of timber which grows upon it. Of this year's produce I have sold £400 worth, and I have now remaining in my Granaries upwards of 1,800 bushels of corn. I have at this moment 20 acres of fine wheat growing, and 80 acres prepared for Indian corn and potatoes with which it will be planted in less than a month.' He had ten convicts allowed him for clearing

and cultivating his farm. On this farm the plough was used for the first time in Australia, in the spring of 1795.

In June 1795 the number of Hawkesbury settlers with their wives and children was 400 or more, and their farms extended 30 miles on both sides of the river. They were at times considerably annoyed by the blacks. In 1798 an area of upwards of 6000 acres was under crop, but in January 1799, owing to a severe drought, the crops were almost a complete failure. The drought was followed by very heavy rain in June, and the resulting floods caused great destruction among the farms, and loss to settlers. In 1801 King reported that out of 10,800 acres of cleared land not more than 8421 were cultivated, mainly because owners were either too ignorant or too poor to utilize them. Four floods in the Hawkesbury during the summer of 1800-1 destroyed produce to the extent of 'sixty weeks' consumption for those victualled from the stores.' At the Hawkesbury the new crop averaged 25 bushels per acre ('but 35 have often been produced'); 12-14 was the average elsewhere. And so the industry went on—confined within the narrow bounds of the county of Cumberland, where most of the soil was unfit for farming and the best areas were subject to disastrous floods. Bligh was the first governor who took agriculture seriously—i.e., as an industry apart from the need of food for the settlement; and it is probable that his interest in it arose largely from his dislike of Macarthur and the sheepowners. 'Our utmost exertions' he wrote in February 1807 'must likewise be to Agriculture to supply the Shipping, and the collateral advantages of a Wool Trade will then be supported by competent means.' After his deposition the area in cultivation fell off by 2000 acres. He was also much interested in manuring, clean cultivation, and the importation of exotic grasses. Macquarie, benefiting from a three-years' lack of floods, reported in 1813 that the harvest was excellent: at the time (according to figures compiled in October 1812) nearly 150,000 acres were in occupation, 85 per cent being pasture-land; 9428 acres were under wheat, 4783 under maize, 1832 under other crops, and 6654 lay fallow. 4521 men were employed in farming, of whom 625 were free.

This represents the maximum effort, one may be sure, of the colony at the moment, i.e. before the crossing of the Blue Mountains. As soon as possible after that achievement wheat was sown at Bathurst, and in March 1816 Macquarie reported that it was 'of a Very superior Quality to the Wheat Generally Grown on this Eastern Side of the Blue Mountains.' In 1821 the official figures showed over 380,000 acres in occupation, 17,000 under wheat, 11,000 under maize in New South Wales; in Tasmania nearly 274,000 acres were occupied, 13,000 of which were under wheat. On the mainland by 1830 the settled areas lay northwards in the alluvial flats of the Hunter valley and at Port Macquarie and Brisbane; southwards along the Illawarra coast; inland from Bathurst to Wellington, and from the Goulburn plains to the Monaro country. In 1838 the total area under crop on the mainland of Australia was 92,912 acres. On that area 48,060 acres of wheat yielded 469,140 bushels: 25,043 acres of maize yielded 556,268 bushels: 2922 acres of barley gave 32,103 bushels: 3767 acres of oats yielded 13,416 bushels: 429 acres of rye yielded 4878 bushels: 39 acres of millet yielded 353 bushels of seed: 1788 acres under potatoes yielded 3496 cwt.: 925 acres in tobacco yielded 4952 cwt.: and 9939 acres of sown grasses yielded 6960 tons of hay. Agricultural labour was greatly needed, and the land revenue was employed to assist migrants from the United Kingdom.

In 1841 the acreage under cultivation (which had doubled since 1833) actually diminished, partly because of the serious financial crisis of that year; but in 1842 a recovery was effected, and by 1845 the cultivated area had increased to 164,000 acres. The fine agricultural country beyond the mountains, however, was still practically undeveloped, as the expense of carting crops to the seaboard was too great. In 1846, therefore, the construction of a railway across the Blue Mountains was suggested; but not till 30 years later was it completed even as far as Bathurst. In 1851-5 the spread of agriculture was hampered by the gold discoveries, the vast influx of adventurers, and the practical cessation of transportation. The cultivated area decreased from nearly 200,000 acres in 1850 to 132,000 in 1852, and did not regain the 1850 level until 1858 (223,000 acres); it then increased slowly to 1864 (319,000) and rapidly to 1866 (451,000), about which figure it fluctuated until 1875; then began another steady increase until 1880 (706,000). These increases correspond roughly to the extension of the railways. Thus by 1864 the Hawkesbury and Hunter valleys had obtained railway connection with the seaboard; in 1869 (a year of sudden agricultural expansion, which was not kept up), the railway had crossed the southern range to Goulburn and the western as far as Bowenfels; and the steady increase of 1875-9 may be attributed to the opening of a western section to and past the rich Bathurst Plains. Not yet, however, was the colony agriculturally self-supporting. Experts in 1870 stated that 'we can produce wheat of a quantity that can stand the competition of the world, but we cannot do it at the necessary price. The cost of labour is too expensive for rude processes, and we have not yet attained to such proficiency in the use of labour-saving machinery as would counterbalance the rate of wages.' And up till 1896 a considerable proportion of the New South Wales population depended for its food-stuffs on importations, mainly from Victoria.

From 1895 onwards the introduction of improved methods of farming coupled with the strain put on owners of unproductive land by Reid's 'unimproved values' land-tax, greatly increased the cultivated area in New South Wales; in 1895-6 only 1,348,600 acres were under cultivation; in 1905-6, 2,840,235 acres; and in 1915-6, 5,796,376 acres. But the war withdrew the pick of the agricultural labourers, and otherwise disturbed industrial conditions, so that in 1919-20 the tilled area was well under four million acres, and by 1922-3 had increased only to 4,696,459 acres, of which 2172 acres were in the Federal Capital Territory.

Tasmania.—In Tasmania the production of crops progressed at first so well that in 1805 (two years after colonization commenced) more wheat was produced than the settlement needed. In the following year, however, crops failed, and the price of wheat rose to £4 a bushel. But good roads were soon made, new land was opened up, encouragement was given to agricultural settlement and soon free settlers arrived from Great Britain, including retired naval and military officers and persons with sufficient capital to make a satisfactory start. Each settler

received a grant of land, the area being in proportion to the capital brought with him, up to a maximum of 2560 acres. The chief products raised about 1820 were wheat, barley, potatoes, and a little oats. The area under cultivation was 8330 acres. The average yields at Port Dalrymple were: wheat 25 bushels per acre, barley 40 bushels, oats 50 bushels. Large quantities of potatoes were sent to Sydney. English grasses were sown extensively for hay, which realized at Hobart £10 a ton; Launceston hay was 50 per cent cheaper. In 1847 the value of grain, hay, and flour exported was £141,377.

The gold discoveries on the mainland caused such an exodus of men from the colony that many districts were almost deserted by the male population; by degrees, however, most of the gold-seekers returned, and in 1853 the island began to show evidences of remarkable prosperity. The Victorian goldfields needed food, and, while South Australia supplied a good deal of wheat, other grains and vegetables were in great request. About that time the lands of north-western Tasmania were opened up, and found to be admirably suited for the production of potatoes. By degrees a lucrative trade in that product developed, but the land was so heavily timbered that clearing was expensive. In other ways, too, progress was slow, partly owing to the system of issuing free grants of extensive areas of land. Up to the end of 1864 a total area of 2,960,765 acres had been given away, and during the same period only 1,278,748 acres had been sold.

As might be expected in the colder climate, Tasmanian agriculture has occupied itself rather with oats, peas, and potatoes than with wheat. The limited area available for cultivation—since great districts of the centre and west are too rugged or too forest-covered to make cultivation profitable—prevented any great development after the early settlers had absorbed the rich and easily attainable patches. The following figures indicate the development which has been possible:—

	1860	1880	1900	1920	1922-3
Acres cultivated	152,860	140,788	224,352	297,383	298,611
Under wheat	66,450	50,022	51,325	28,284	25,244
Under potatoes		9,760	23,068	32,000	34,407
Orchards		6,717	11,485	37,013	34,689

In spite, therefore, of her small area Tasmania produces more potatoes than any State except Victoria, and more fruit than any except Victoria and New South Wales.

Victoria.—In 1839, four years after the beginning of the settlement, very little land was cultivated, but by 1842 an area of 8124 acres was under crop (2432 under wheat). In 1845 the cultivated area had increased to 25,134 acres (11,141 under wheat). About Melbourne wheat, oats, and potatoes were grown. At Western Port a little maize was cultivated, at Portland wheat, oats, and potatoes and at Geelong wheat, oats, barley, and vegetables. The conditions that hampered farming in New South Wales—barren ranges which intervened between the best farming districts and their port, and the consequent high cost of transport—did not hamper Victorians to the same extent, and, in spite of land laws that by no means encouraged immigrants to farm, over 50,000 acres were under cultivation by 1850. The inrush of gold-seekers and the depletion of local labour threw 20,000 acres out of cultivation in the next few years; but, as in Tasmania, the needs of the diggers stimulated production, better legislation opened up the lands (in 1857 alone half a million acres were sold), and by 1865 448,000 acres were being cropped and the necessary importation of food-stuffs had decreased by at least 60 per cent.

A protective tariff imposed in 1871 benefited agriculturists considerably—an import duty of 1s. for every hundred pounds' weight of grain and pulse of every kind; on onions 20s. a ton, on potatoes 20s. a ton, and so on. During the same year the completion of 315½ miles of railway also advantaged the farmers, but the colony was still obliged to import over a million bushels of wheat. In 1885 a royal commission on vegetable products recommended a 'judicious system of offering bonuses for new vegetable products, and for the further development and improvement of vegetable products already established.' By the end of 1890 over £370,000 had been paid in bonuses, and in 1894 the commission claimed great credit for the good done.

About 1880 Victoria began to utilize her share of the 'mallee' country, a region which occupies the great bend of the Murray from (roughly speaking) Swan Hill to Murray Bridge. Settlers were aided to cultivate their farms by the prior destruction of the dense scrub which covered nearly 11 million acres of Victorian territory; it was too thick to clear by ordinary methods, so heavy rollers and wooden frames were dragged over the mallee with traction engines, the timber thus crushed down was burnt off when dry, and the land then ploughed with stump-jumping ploughs (a local invention) and harrowed with stump-jumping harrows. The stumps were afterwards removed by degrees. For many years before the advent of the Commonwealth Victoria was the granary of Australia; envious squatters from New South Wales might call it contemptuously 'the cabbage-garden,' but its prosperity, founded on gold, was ensured and strengthened by agriculture; not until 1913-4 did it lose the agricultural primacy of Australia. In 1860 it had under crop 387,282 acres; in 1880, 1,548,809; in 1900, 3,114,132; in 1920, 4,489,503. The latest figures available—those for 1922-3—show 4,862,548 acres under crop, of which more than half was in wheat and nearly a third in oats grown for seed or hay. While New South Wales grows more wheat and maize, Victoria tops all the other States in oats, hay, fruit, and potatoes; and its proportion of cultivated to uncultivated land —eight per cent—is nearly four times as great as that of New South Wales (the next State) and ten times that of the Commonwealth as a whole.

Queensland.—In the early days of settlement Queensland was considered to be suited for pastoral purposes only, though when a penal settlement was formed at Brisbane, and a smaller one at Ipswich, land near those centres was cultivated, chiefly for fruit and vegetables. Wheat-growing was tried with some success near Ipswich, and maize throve at both settlements. In 1847 Dr. Lang (q.v.) conceived a scheme for utilizing the coastal districts to grow cotton, and in 1849-50 brought out three shiploads of migrants to establish a cotton-growing

colony near Brisbane (see COTTON). Ten years later, however, when Queensland was separated from New South Wales, the area of cultivated land in the new colony was 3557 acres only, situated near Brisbane, Warwick, and Toowoomba. During the American civil war (1861-5) Lang's idea again came to the front, and for some years Queensland cotton-planters made money; but with the return of peace the price of cotton fell, and the industry was ruined. During those years, however, some planters had been experimenting with sugar-cane, and the introduction of Kanaka labour by Robert Towns for a time supplied the cheap labour that the cane-fields so urgently needed. The relation of the sugar industry to Queensland agriculture in general is shown in the following table:—

	Area under crop	Area under cane	
1860-1	3,353	—	
1870-1	52,210	6,342	(12%)
1880-1	113,978	20,224	(17¾%)
1900-1	457,397	108,535	(23¾%)
1920-1	779,497	162,619	(20%)

In 1922-3 24 per cent of the total cultivated area was under cane—202,303 acres out of 835,060. The physical geography of the State makes it especially the home of tropical and subtropical crops and fruits. It produces not only 90 per cent of Australian sugar, but 41 per cent of its maize. Its wheat crop is small, although varieties suitable for subtropical conditions have been bred by several agricultural experts, notably Joseph Bancroft (q.v.). Southern Queensland has large areas under green forage crops, mainly maize, lucerne, and sorghum for dairy purposes; in this respect Queensland heads the States, with 35 per cent of the total product of the Commonwealth.

South Australia.—When the first settlers at Adelaide saw the hard, sun-baked soil of their new country, they were despondent about raising crops; a trial, however, made on 20 acres within the town-limits showed that excellent wheat could be produced, and since then wheat has been the staple crop of South Australia. In 1850, about ten years after the first wheat trial was made, the area of land under cultivation was 64,728 acres (41,807 under wheat). The gold discoveries, as in other colonies, at first depleted the agricultural labour market, but after a while stimulated agriculture very greatly; in 1860 the area under cultivation had increased to 428,816 acres, of which 273,672 were under wheat. From that time onwards agriculture progressed steadily, and exports of wheat and breadstuffs increased. At one time a little flax was grown, and fibre marketed in England realized a good price.

As settlement increased, cultivation extended into regions hitherto regarded as desert—e.g. the South Australian part of the mallee country. South Australia began operations in her mallee districts much later than Victoria, but is now 'gridironing' it with railway lines and adding its area to her wheat-fields. The following figures indicate her success:—

	Acreage under crop	Acreage under wheat	
1860-1 ..	359,284	273,672	(76%)
1880-1 ..	2,087,237	1,735,542	(83%)
1900-1 ..	2,369,680	1,913,247	(80½%)
1920-1 ..	3,231,083	2,167,646	(67%)
1922-3 ..	3,575,452	2,453,086	(68½%)

The decrease in the percentage of wheat-land since 1900 is partly due to a great increase in the acreage put under barley, which began to expand in 1902, and has since then decupled itself; South Australia in 1922-3 produced over 56 per cent of the Commonwealth yield of barley.

Western Australia.—In 1831, two years after the Swan River settlement was founded, 200 acres only were under cultivation; in 1834 the 1600 settlers had managed to clear and cultivate 918 acres, of which 364 were under wheat. Two years later sufficient wheat was produced to meet the requirements of the colony. In 1838 the settlers had increased to 2000, and cultivated 2447 acres, but suffered from lack of labour; ordinary farm-servants' wages were from £2 to £3 10s. a week with board, etc. In 1845 cultivation had increased to 4836 acres (3313 under wheat). Finding it impossible to procure labour, the settlers petitioned the British government to constitute the colony a penal settlement, and the first shipment of convicts landed in June 1850. From that time onwards the cultivated area increased, but very slowly; even the discoveries of gold at Coolgardie (1892) and elsewhere did not greatly stimulate agriculture, though after the establishment of the Commonwealth the annual expansion was more marked. After 1905, however, a considerable growth was recorded, as the areas along the York-Albany railway line and the coastal region from Perth to Bunbury were opened up for settlement and branch lines thrown out into the new tillages. In the season of 1860-1 24,705 acres were under crop; in 1880-1, 57,707; in 1900-1, 201,338; in 1920-1, 1,804,987. In 1922-3 2,274,998 acres were under crop, 1,552,868 of them under wheat.

An account of the progress of agriculture in the *Northern Territory* will be found under that heading.

General.—Australian agriculture reached its maximum of production in 1915-6 when, as the result of a special effort to supply war-needs oversea, 18,528,234 acres were put under cultivation. The German 'submarine campaign,' however, soon made it impossible to ship foodstuffs to England, and production fell off rapidly until 1920-1. In 1922-3 the tilled area for all Australia was 16,543,555 acres, of which 59 per cent was in wheat, 10 per cent in other cereals grown for grain, and 25½ per cent in hay and green-fodder crops. In New South Wales, Victoria, South Australia, and Western Australia wheat-growing occupies the biggest area; Queensland allots most space to cane, and Tasmania to oats. The average yield of wheat per acre fluctuates greatly: in 1922-3 the average for all Australia was 11.21 bushels, but for Tasmania the average was 22.56 bushels and for Western Australia 8.92. In 1920-1 the Australian average was 16.08 bushels, but this was exceptional and only once (in 1866) exceeded in the history of Australian agriculture. More attention has been given in recent years to the improvement of the industry by extending the practice of fallowing and the rotation of crops; it is still true to say, however, that on the whole the Australian wheat-farmer grows the one crop year after year in the same field, occasionally turning up the soil at the end of the harvest and allowing it to lie fallow until the next sowing period; though where dry farming (see WHEAT) is practised a fallow between crops is, of course, essential. Much land previously considered useless or inferior for cultivation has of late years been made available by the use of fertilizers, especially phosphate (see MANURES and MANDATED TERRITORIES). The development

of irrigation (q.v.) has also extended the area of intensive farming.

State governments assist farmers both financially and educationally. Advances may be obtained on the security of a first mortgage from special branches of the State savings banks (in some cases from separate agricultural banks) to pay off existing liabilities, to make agricultural improvements, to erect permanent buildings, etc. The various State departments of agriculture control schools and training farms (for which see AGRICULTURAL EDUCATION); they also carry out investigations in entomology and vegetable pathology (e.g. in New South Wales extensive experiments have been made to ascertain the most effective method of protecting stored maize from insect pests), examine specimens sent to them to determine the presence and nature of disease, and breed new varieties of seed—some States distribute such seed freely for experimental purposes to farmers. Occasionally also departments assist in developing markets by exhibiting samples of produce and collecting information for publicity overseas.

Share-farming.—During the greater part of the 19th century Australian farming was carried on either by owners or by ordinary tenants. But about 1893 there grew up in south-western New South Wales an adaptation of the metayage system so common in Italy and France. The details of 'share-farming' contracts varied with the district: thus in some cases the landowner provided everything but the labour and took two-thirds of the crop in return, in others the farmer provided plant, labour, and half the bags required and took half the crop—in one such case, as a stimulus to good farming, the whole yield between 20 and 25 bushels per acre went to the farmer as a bonus, so that a 30-bushel crop would go 12½ bushels to the owner and 17½ to the farmer. Where the landowner takes an active interest in the farm these contracts have been found very beneficial and educative: indeed, good landlords have always regarded them as educational, have looked forward to losing their tenants after a few years, and have often refused to renew the contract after that time. An official enquiry made in 1910 elicited from a number of former share farmers the opinion that five years of it was long enough to set any man on his feet and let him buy land of his own, while if the man had a little capital to begin with he should be independent in three years. The system has also been applied to dairy-farming. In a typical case the owner provided stock, milking-plant, residence, and seed for the first food-crops, and the tenant labour, agricultural plant, and horses; the tenant took 7s. 6d. for every calf reared and half the net proceeds from butter. Of late years the system has gained much popularity, and except in Tasmania the man without capital prefers share-farming to ordinary tenant-farming.

See AGRICULTURAL EDUCATION, DAIRYING, and articles on the various crops. For the early settlements near Sydney see J. F. Campbell's 'Dawn of Rural Settlement in Australia' in vol. xi of the *Journal* of the Royal Australian Historical Society. W.S.C.

Agrimony. See ROSACEAE.

Albacore (*Thunnus germo*). Though this fish has been recognized from Australian waters upon one occasion only, it is probably plentiful in the open seas along our coasts, together with many other oceanic members of its family, the Scombridae. It is closely allied to the well-known tunny, but is distinguished from that species by its much longer pectoral fins. The albacore attains a length of four feet, and is distributed over all warm seas. It is almost worthless as food. A.R.McC.

Albatross, a large sea-bird of the family Diomedeidae, peculiar to the Pacific and Southern Oceans. Most of the species found in the Southern Ocean appear in Australian seas during the winter, and are familiar to voyagers along the coast-line from Brisbane south and west to Geraldton in Western Australia. The largest and most widespread is the Wandering Albatross (*Diomedea exulans*), which in its first plumage is dark-brown with a white face, but gradually becomes whiter as it grows older, till it assumes a plumage entirely white except for the black tips to wings and tail. In this species the span from the tip of one wing to that of the other is usually between 10 and 11 feet. Smaller forms of albatross, known to sailors as mollymawks (originally the Dutch name for the fulmar petrel), may be distinguished by the fact that the dark coloration of the wings extends right across the back. Four kinds are common in Australian waters; one of them, the White-capped Albatross (*Diomedea cauta*), nests in numbers on Albatross Island in Bass Strait—the only locality in Australia where albatrosses are known to breed. The two species of Sooty Albatross (*Phoebetria*) also visit Australian waters. They are more slender than the other kinds, dusky in colour with a white ring round the eye, and regarded as the most expert fliers of the family. W.B.A.

Albizzia, a genus, chiefly tropical, of the family Leguminosae, consisting of trees or shrubs with mimosa-like foliage, usually known as 'tongue pods,' and sometimes mistaken for wattles. The flowers occur usually in globular heads, their elongated stamens (white or pink) forming a conspicuous feature. The Western Australian *A. lophantha* is a useful fodder-plant; its dried roots contain about 10 per cent of saponin. *A. procera* (Tree-coma of the aborigines of the Northern Territory) exudes a dull, horny-looking gum, the soluble portion of which is clear and almost colourless. The tree has a close-grained, easily-worked timber resembling walnut; it seasons well, and is used for agricultural implements, bridges, and houses. In India tea-planters use the wood for stakes, and occasionally for tea-boxes. *A. Thozetiana* and *A. toona* both supply useful timbers.

Alder-flies. See MEGALOPTERA.

Aleurites, a genus of plants of the family Euphorbiaceae, contains only a few species, mostly natives of tropical Asia and Malaysia. One species, *A. triloba* (Candle-nut Tree), is found in Queensland—where it reaches a considerable size—as well as throughout the northern tropics from India to the Hawaiian Islands. It has 3-lobed leaves, and produces a number of large, spherical, fleshy fruits with a hard, almond-shaped, bony stone. The kernel is edible, in flavour somewhat like the common walnut, but rather rich; oil constitutes 50 per cent of its matter. The South Sea islanders string these stones upon a reed, or strip of palm-leaf, and use them as torches; they will burn for hours with a steady light. The oil is very fluid, of an amber colour, without smell and readily saponifiable; it has been used for candle-making, and is considered equal to rape oil. The cake, after the oil has been expressed, is good cattle-food.

Alfalfa. See LUCERNE.

Algae. Australia, owing to its extent and situation, provides a remarkable epitome of this interesting group of plants. Of simple structure, reproducing themselves rapidly by simple means, they appear in great numbers where the environment is suitable. The majority luxuriate on the margins of the sea, but vast numbers live in fresh or stagnant water, while others grow on moist soil, in damp crevices of rocks, or on the bark of trees—everywhere, indeed, where they can find enough water to live in. As an ocean-lapped island Australia is admirably adapted for the growth of marine algae; as an island of continental dimensions, with its northern shores in the tropics and its southern shores in the colder temperate zones, it possesses a wonderful variety of seaweeds proper. In the rivers and creeks of the fertile coastal districts and scrub jungles, freshwater and forest forms appear, dwindling sadly towards the dry interior.

By a rare chance the colour of algae is associated with special reproductive characters, so that members of the four great sub-divisions are in general easily recognized. The algae are classified as Blue-green (Cyanophyceae or Myzophyceae), Green (Chlorophyceae), Brown (Phaeophyceae or Fucoideae) and Red (Rhodophyceae or Florideae). The habitats of the four groups are in general diverse. The Cyanophyceae abound on the slime of mud-flats; the Chlorophyceae live in fresh water or in a narrow fringe round the seashores, usually confined to the strip between tidemarks; the Brown weeds are almost exclusively marine, growing at somewhat greater depths than the Green; while the Red weeds, also almost exclusively marine, prefer fairly deep water. Thus Green weeds may be observed coating the upper parts of piles and wharves, while masses of Brown weeds are attached below. The brighter Red weeds are more rarely observed while growing, and appear chiefly when thrown up on the shores by storms. They are best obtained by dredging.

The Cyanophyceae consist of single cells, or of colonies of such cells, or of strings of cells forming filaments. The filaments may be straight or sinuous, and in the latter case are often crowded together in a tangle. Some have pseudo-branches, the branches not growing directly from cells of the main axis but lying in position alongside it. A few are truly branched and form cushion-like masses or tiny bushes. Almost all are furnished with sheaths that develop a gelatine-like substance which encloses the filaments, binding them together in lumps of various shapes. Many possess a peculiar and unpleasant odour. In a Nostoc which sometimes appears in millions in ponds the filaments are like tiny corkscrews with many turns, the cells are of a bright yellow colour, and the odour is unbearable. Other olive-coloured Nostocs occur as little lumps of jelly on paths or meadows after rain. The Oscillatoriae form blackish-green skins covering mud or dark-coloured floating masses. Some species grow in hot water. These plants possess the property of spontaneous motion, the whole filament moving like a worm or snake. Their odour, too, is often offensive. Some of the pseudo-branched genera, as *Scytonema, Tolypothrix, Stigeonema* and some of the branched genera, as *Calothrix,* are very beautiful objects under the microscope, and are the most highly developed members of the group. These are mostly found on rocks in running streams, though some *Calothrix* are marine. The Cyanophyceae show no sexual form of reproduction. The cells divide, the daughter cells separating or remaining attached to form the filament. Certain cells or groups of cells grow larger than the others and persist to form the origin of the next season's growth. The colour of the plants is due to the admixture of green chlorophyll with a bluish pigment (phycocyanin) and occasionally other pigments.

The Chlorophyceae or Green Algae are more conspicuous. They live in fresh or in salt water. The freshwater forms are very varied. The species of Coleochaete appear as small disks closely attached by the whole lower surface to the leaves or stems of aquatic plants like *Vallisneria, Triglochin* or *Nitella.* Each plant branches out in one plane from a centre, forming a rosette; each of the vegetative cells is furnished with a long bristle. It reproduces asexually by moving ciliated spores (zoögonidia) and sexually by oöspheres (germ-cells) and antherozoids (sperm-cells). *Oedogonium* consists of unbranched filaments attached at the base, usually to the submerged parts of water-plants. The filament consists of a chain of cylindrical cells, which grow lengthwise in a curious way. The cellulose wall at the apical end splits in a circle, thus allowing fresh growth to prolong the cell. This may occur five or six times, so that the cell appears to be crowned by the cellulose caps cut off from it. Sexual reproduction is effected in certain of the cells, sometimes singly, sometimes a string of them in order, which become oöspheres. These are fertilized by active antherozoids, produced in male cells of the same or of other filaments. When ripe, the swollen yellow or brown oöspores are very conspicuous. As the vegetative cells die away, the oöspores are set free, sink to the mud at the bottom, and rest until the next season summons them to germination. A large number of species occur in Australia. *Bulbochaete* is very nearly allied to *Oedogonium,* but is constantly branched.

The Protococcoideae comprise the two families, Volvocaceae and Palmellaceae. The Volvocaceae include the colonies of *Volvox, Eudorina* and *Pandorina,* so well known to microscopists. Those of *Volvox* may contain as many as 12,000 cells. The colony swims freely as a globe, rotating by means of the cilia of the surface cells. Often eight or more smaller spheres, young colonies, are seen in the interior of the mother sphere. The colonies are reproduced by antheridia and oögonia. In *Eudorina* the cells are 16 or 32. In *Pandorina* the cells, 8 to 64 in number, have each a red spot and two vibratile cilia. The Palmellaceae are mostly unicellular plants either isolated or combined in families, the cell imbedded in a firm mucilage. They rapidly reproduce by fission and hence are often found in great numbers in water or in damp places. Such are the various species of *Palmella, Pleurococcus* and *Protococcus.* In *Scenedesmus* the cells are cylindrical, 2 to 16 ranked side by side in a single series, the end-cells often prolonged at the extremities into a narrow awn. *Pediastrum* forms small flat disks, the forked cells radiating from the centre, often with interspaces left between the cells. The most beautiful of these coenobia or family groups of cells are those of *Hydrodictyon,* which form delicate green nets which float freely in clear water and may attain to a length of two feet or more. Most of the Protococcoideae are cosmopolitan.

Among the most attractive freshwater Green

Algae are the Conjugatae, with the families Zygnemaceae and Desmidiaceae. In both, the plants increase either by bipartition of the cells, or quasi-sexually by the conjugation of two apparently similar cells. The result of the conjugation is a zygote, a single cell which surrounds itself with a thick firm wall and then rests till another season. The walls of the ordinary vegetative cells form mucilaginous outer layers which render the plants glairy to the touch. The chlorophyll-bearing portions of the protoplasm (the chlorophores) are strap-shaped, more or less spirally disposed, or are star-shaped. In Zygnemaceae the cells are cylindrical, attached end to end to form simple unbranched filaments. In *Mougeotia* the chlorophores are axile and straight. In *Spirogyra* they are parietal and usually wound round in several spiral turns, one, two or several such spiral bands occurring in each cell. The filaments float freely and often in such numbers as to form conspicuous green clouds in the water. *Spirogyra* hunters are often, however, liable to disappointment in their quest, for there are several other filamentous algae, such as *Conferva, Rhizoclonium* and *Zygnema*, which form similar clouds, and in one season certain species of *Spirogyra* may abound in a particular pond or stream and in the next may be entirely absent. *Spirogyra* fruits in the late spring or summer, the plants turning yellow when the operation is near completion. The chlorophores in *Zygnema* are much branched, the rays spreading outwards in starwise fashion.

The Desmidiaceae comprise a few genera, such as *Desmidium* and *Hyalotheca*, in which the cells form filaments included in a gelatinous sheath, and a large number of genera in which the cells are quite distinct and float separately in the water. Each cell is symmetrical about a median longitudinal plane and also with regard to another median plane at right angles to the axis of growth. There is generally a circular constriction of the cell in the latter plane, which divides it into two more or less well-marked semi-cells. Hence most of the Desmids appear to be double. In the filamentous forms the cells are cylindrical, but in the free forms the shapes taken are extremely diversified. Some appear as long rods. In others the semi-cells are urn-shaped, spindle-shaped, ellipsoidal, spherical, hemispherical, and crescent-shaped. The surfaces are smooth or crenate, tuberculated, or with projecting stellate outgrowths, which are sometimes very complicated. Two cells conjugate by laying themselves with their axes at right angles to one another; a process grows out from the middle of each, these unite with one another and form a spherical space in which the zygote is formed. It then appears as a cell with thickened walls, quaintly surrounded by the empty semi-cells of the parent plants, all the protoplasm of which has been used up in the formation of the zygote. In the filamentous forms the cells usually separate before the process of conjugation. The commoner and most noteworthy genera of free Desmids are *Closterium* (falcate or lunate), *Penium* (straight, cylindrical or fusiform), *Docidium* (cylindrical, truncate), *Cosmarium* (orbicular), *Euastrum* (oblong with sinuous borders), *Micrasterias* (orbicular, the margins radiating in much divided processes) and *Staurastrum* (orbicular in profile, with tri- or pluri-angulate apices and radiating horn-like processes). *Closterium, Penium* and *Docidium* are but slightly constricted, whereas the semi-cells in the other named genera are attached only by a narrow isthmus. A peculiarity in some of the Desmids is the presence of definite small spaces in the apices, occupied by tiny dancing corpuscles.

The Ulvaceae supply the commonest green weeds of our seashores. Attached to rocks and stones they luxuriate in the quieter waters of our harbours. They furnish the vegetation prized by molluscs and fish, and doubtless, at a pinch, would serve as useful human food. They are entirely membranous without stalks or veins, and are composed of cells rich in chlorophyll. The common sea-lettuce, called *Ulva lactuca* by Linnaeus, is actually used as a vegetable. *Ulva* grows in broad leaf-like expansions; the cells of the frond are arranged in two layers giving to it a fair amount of consistency. In *Monostroma*, some species of which grow in fresh water, the frond is composed of a single stratum of cells. In *Enteromorpha* the membrane forms a tube, rounded or flat. *E. linza* is a handsome species, growing to two feet in length, with fronds two to four inches wide, much resembling the narrow forms of *Ulva*, but distinguishable by its tubular structure. *E. intestinalis* and *E. compressa* are much used for bait by fishermen. *Enteromorpha* is often carried on the bottom of ships from one quarter of the world to another. Many of the Ulvaceae are cosmopolitan. In all the cells divide and group themselves in pairs or fours. In *Ulva* reproduction is effected by biciliate unwalled zoögonidia; one of these may be formed out of the protoplasm of almost any cell of the frond and escapes by a pore in the surface; two zoögonidia unite to form a 4-ciliated zygote, which swims to a resting-place and later grows into a new plant. Among allied forms are *Conferva*, simple unbranched filaments, forming tangles in fresh or stagnant pools, *Draparnaldia* and *Stigeoclonium*, branched freshwater forms, *Chaetophora*, forming small jelly-like masses attached to aquatic plants, and the family Cladophoraceae. In this family we have *Chaetomorpha*, simple filaments attached to rocks or to other algae, often growing close together like grass blades—but in *C. Darwini* forming strings of large glistening round cells like necklaces of pearls; *Rhizoclonium*, also unbranched filaments, often floating in tangles in both fresh and sea water, a few colourless hooked rhizomes distinguishing it from *Conferva;* and *Cladophora*, much-branched filamentous plants, each branch a row of cylindrical cells. Some of the Cladophorae live in fresh water and more in the sea. The former are slender moss-like plants, the latter present a great variety of form and colour. Some form stiff cushions growing closely to the rocks, or may be found floating in spongy balls. Some Victorian and Tasmanian species, a foot in length, form graceful plants as they spread and wave in the water. *Microdictyon* grows in sheltered bays in warmer waters; the dark-green fronds, consisting of an elegant network of branching cells, may spread to a foot or more in diameter. It is common, summer and winter, in Botany Bay. *Struvea*, found in Western Australia, forms erect fans with pinnate branches.

In the interesting order Siphoneae we have the remarkable phenomenon of a single vegetative cell taking on the form of an entire plant often of elaborate contour. The protoplasm is continuous from end to end of the plant, from the rhizoids, which attach it, to the tips of the branches. Instead of possessing a single obvious nucleus, the nuclear matter is distributed in tiny granules which are difficult to identify, requiring high powers of the microscope and special re-agents. Sexual generation is met with in some

genera; but in the most highly-developed genus of all, *Caulerpa*, long under observation in all parts of the world, no organs of reproduction have ever been detected. *Vaucheria* consists of simple or sparingly-branched filaments, which usually form thin green carpets on moist soil; it produces antheridia and archegonia. *Acetabularia* is marine; it has a vertical axis which bears whorls of speedily deciduous sterile branches below, and at the apex a whorl of club-shaped branches which make a little cup. In the branches of the cup numbers of asexual spores are formed. *Polyphysa* is a somewhat similar marine form, but the fertile apical whorls are rounded vesicles which do not form a cup. *Bryopsis*, also marine, is much-branched, the upper branches beautifully pinnate, giving a graceful feathery appearance to the plant. *B. plumosa*, is the commonest species, and is abundant in calmer waters around our coasts. Reproduction is effected by means of zoögonidia. The contours of *Caulerpa* forecast those characteristic of many higher groups of plants. *C. parvifolia* has slender branches having apparently ordinary petiolate leaves; *C. sedoides* resembles a stonewort, *C. taxifolia* a yew branch, *C. Sonderi* (shown on Plate v. fig. 1) water milfoil, *C. Browni*, *C. Muelleri* and *C. hypnoides* simple or branched club-mosses, and *C. cactoides* a fleshy cactus. *C. complanata* is shown as fig. 3. There are many kinds of *Caulerpa* in the seas around Australia, and doubtless more will be discovered by the trawl. *Codium* has flourished excessively in our seas. All the species have a spongy structure, the filamentous branches and branchlets finally terminating on the surface in club-shaped end cells which constitute a soft pile. The frond may be laminar (*C. laminarioides*), dichotomous (*C. Muelleri*, *C. galeatum*, *C. mucronatum*, *C. tomentosum*), globular (*C. mammillosum*, *C. Bursa*) or an irregular spongy mass (*C. adhaerens* and *C. spongiosum*). *C. mucronatum* and *C. tomentosum* form the dark green, almost black clumps of finger-like fronds often seen in exposed rock-pools and passages between reefs. *C. galeatum* is a handsomer species, growing to a length of two to three feet in deeper water. *C. adhaerens* forms a dark green dense mass clinging close to the rocks and following all the irregularities of the rock surface. Reproduction is effected by zoögonidia produced in certain of the club-shaped superficial tips of the branches. *Halimeda* has fronds apparently composed of joints, usually incrusted with carbonate of lime and in consequence very brittle when dried. The branches spread out in fans or fingers, the whole plant, like *Codium*, having a somewhat convex appearance. It is a tropical genus, and has played a very considerable part in the building of the so-called coral reefs and islands.

The Brown Algae are, with trifling exceptions, entirely marine. They are in general of much firmer texture than the Green, and include all the largest kinds of seaweeds. The floating weeds of the Sargasso Seas consist of the fronds of *Sargassum*. Most, however, of the Brown weeds are found on coasts of the temperate and subarctic zones, where they abound. On the coasts of Britain and France the numerous *Fuci* and *Laminariae* yield the harvests of kelp, used for manure. The largest kelps of Australia likely to be of commercial importance are found on the coasts of Victoria and Tasmania. The Brown Algae, apart from the considerable nitrogenous content of the plants, contain in their substance potassium, chiefly as chloride, but also as iodide. Kelp was formerly the chief source of iodine, and will always be a reserve source, when the mineral deposits have been exhausted. Potassium is more generally required than iodine, because of its importance as a food constituent of land crops. The power of selecting potassium and rejecting sodium compounds is seen in the composition of the efflorescence of crystals which appears on the dried weed. If the weed be washed in fresh water to remove any adhering salts of the sea water, and then slowly dried, it becomes coated with white crystals as of hoar frost. On analysis these crystals are found to consist of a compound of about 60 per cent of potassium chloride and 40 per cent of mannitol (mannite), without a trace of sodium chloride. The author found precisely the same composition in efflorescences on New Zealand and New South Wales kelps of quite different genera. Hence the value of abundant and accessible growths of kelp weeds. There should be a future for an important kelp industry in both Tasmania and New Zealand.

Quite a number of the larger Fucoideae produce floats which, often mistaken for berries, really serve to buoy up the heavy plants, maintain a more or less erect growth, and bring the fronds to the light. *Cystophora*, *Cystophyllum*, *Phyllospora*, *Hormosira*, *Macrocystis* and most of the *Sargassa* produce these floats, those of *Macrocystis* being very large. The floats are formed out of tissues at first solid; a hollow gradually appears, extends, and is filled with gas. This gas consists mainly of nitrogen and oxygen, but not in the same proportions as in ordinary air, or in the air dissolved in the sea water. If analysed in the daytime, after the plants have been exposed for some hours to the action of light, no carbon dioxide can be detected, but only nitrogen and oxygen—the latter in less proportion than in ordinary air, and far less than in the gas which can be collected by boiling sea water. If analysed in the early morning, after the plants have been for some hours in the dark, a percentage of carbon dioxide is found, and the percentage of oxygen is reduced. It seems clear that the gas is prepared by the plants themselves, and is not merely absorbed air. Considering the composition, and especially the free nitrogen, it seems probable that the chief source of the gas is a mixture of gases dissolved in the sea water. The weeds obtain all their food supplies from the surrounding sea water. They reject certain salts—as sodium chloride—and it is probable that the weeds which do not form floats reject the nitrogen dissolved from the air. Plants which do form floats make use of the nitrogen as the chief component of the gas of the vesicles. The origin of the oxygen is more difficult to settle. It may be derived from the oxygen dissolved in sea water, or from the splitting up of the carbon dioxide by the chlorophyll of the plant-cells. The variation in the amount of carbon dioxide shows that the latter source, the metabolism of the plant, is not excluded; but most likely the bulk of the oxygen is what is left over when the plant has taken all that it needs from the gas-laden water which it has absorbed.

There are over 160 species of *Sargassum* recognized, of which about one-half are met with in Australian seas. They are much-branched plants with slender stems which bear leaf-like organs. The fruit appears in high summer near the extremities of the branches as small fusiform or cylindrical receptacles arranged in cymes or racemes. The reproductive organs occur in tiny

recesses (scaphidia) hollowed out in the surface of the receptacle and communicating with the exterior by a pore. Each scaphidium contains a single oösphere or racemes of antheridia. Several genera of the family Sargassaceae are endemic, or at most extend to New Zealand. *Sargassum, Cystophyllum,* and *Turbinaria* are widely distributed in the tropical seas, but most of the Australian genera are confined to the south. The most important are *Seiroccus, Scytothalia, Cystophora* (fig. 11) with 21 species, *Scaberia* and *Phyllospora.*

The Fucaceae, which predominate in the cold waters of the northern hemisphere, have but few representatives in Australia. The only genera with us are *Hormosira, Myriodesma* and *Xiphophora. Hormosira Banksi* grows in clumps of simple or dichotomous fronds in rock-pools or in the surf. Each branch looks like a necklace of rugged brown bead-like segments which may be globular, cylindrical, or obconical, apparently strung on a very slender cord. Each segment, when mature, is hollowed out in the interior and serves as a float. The scaphidia are developed in the surface of the segments, male and female on different plants. While in the northern *Fucus* the number of oöspores in an oögonium is eight, in *Hormosira* the number is four. *Myriodesma* has flat fronds with no vesicles; the scaphidia are scattered over both faces of the frond and are hermaphrodite. *Xiphophora* is a stiff-looking dichotomous plant with narrow linear segments; it has no floats, and the oögonia, as in *Hormosira,* contain four oöspores.

The Durvillaceae form a small family, of which *Durvillaea* is sub-antarctic and the other three genera, each possessing but one species, are outliers. The three are strikingly unlike in external appearance. *Sarcophycus* is the giant of our seaweeds, with stems stout enough for the Tasmanian fishermen to moor their boats to, and irregularly divided broad leathery fronds which may reach a length of 30 feet. Such a plant is attached to the rocks by a disk six inches in diameter, and grows in the wildest turmoil of the breaking waves. *Splanchnidium* consists of clumps of short brown tubular slimy fingers, not more than six inches long and usually shorter, growing on the rocks along exposed sea-fronts. *Notheia* is a much slenderer branched form, which lives as a true parasite and usually selects *Hormosira* as its host. It is the only known parasitic alga in Australia. The scaphidia in the Durvillaeaceae are scattered over the surface of the frond and each contains several oöspores.

The Dictyotaceae are plants of no great size which grow in fan-shaped or lobed flat fronds, often zoned, striated or fenestrated from the rectilinear arrangement of the cells, and reproducing chiefly by means of asexual tetraspores which appear in patches (*sori*) on the fronds. *Padina* forms curled and concentrically zoned fronds, glistening in the water in peacock hues, and spreading in fans or cowls from a dense hairy base. *Zonaria, Gymnosorus* and *Homoeostrichus* have flat zoned fronds, spreading in fan-shaped or crenate lobes. *Dilophus* and *Dictyota* have dichotomous fronds without any midrib, while *Haliseris* has larger similar fronds with distinct midribs.

The remaining order of Brown Weeds, the Phaeozoosporinae, reproduces by means of zygotes formed by the conjugation of zoögonidia. The families and genera are very diversified in form. *Adenocystis, Ecklonia* and *Macrocystis* are our representatives of the family Laminariaceae, so widely distributed in the northern hemisphere. *Adenocystis* is a small Tasmanian plant which grows as an inflated ellipsoidal sac on a short stipes. *Ecklonia* (fig. 13) spreads out in a multitude of broad pinnatifid fronds often prickly with marginal spines. It is smoother in the harbours, but very rough and prickly when growing on the ocean front. It is our commonest Laminarian, growing on the eastern, southern and western coasts in profusion, forming thickets in water a few feet deep. In *Macrocystis* long strap-like leaves are borne on one side of a slender stem, each leaf petiolate with a float at the apex of the petiole. The terminal segment is broad and splits off new leaves in succession. Near Cape Horn *Macrocystis* grows to a length of many fathoms, and is comparable in mass to a forest tree; but with us the length of the stem rarely reaches 30 feet.

The Sporochnaceae comprise a number of elegant plants, adorned with plumes composed of tufts of filaments. *Bellotia* and *Encyothalia* are peculiar endemic forms, each consisting of a single species. *Bellotia* (fig. 9) grows as a solid slim cord, repeatedly branched in an umbellate fashion and bearing heads of plumes which surround the sporangia; it is from one to two feet in height and of a dark olive-brown colour, the tufts of filaments being greener. It is found in Bass Strait. *Encyothalia* has a cord-like stem with lateral branches of about the same length and colour as *Bellotia.* Stem and branches are beset with thin setaceous ramelli crowned with a dense pencil or plume of very slender filaments. It is confined to Western Australia. *Sporochnus* is a beautiful genus, the plants more delicate than in the other two genera; much-branched, of a greenish olive colour (it may easily be mistaken for green seaweed) and with each fertile twig crowned by a plume of very fine filaments. Australia is the headquarters of the genus.

There are many genera of Chordariaceae in our seas—*Eudesme, Bactrophora, Myriocladia, Mesogloia, Liebmannia*—which grow out in long glairy vermiform fronds, with a longer or shorter pile all over the surface.

Encoeliaceae include a number of vesicular genera. *Asperococcus bulbosus* looks like a string of sausages. *Colpomenia* is irregularly globular and may grow to the size of a man's head. It is complained of as an oyster-thief, growing on young oysters, and, as it inflates, rising in the water and floating off with the mollusc.

Other common genera of the Phaeozoosporinae are the small feathery species of *Ectocarpus* and *Sphacelaria.*

The Red algae are much richer in species than the Brown. They are almost exclusively marine; a few species of *Batrachospermum* and *Chantransia,* however, live in fresh water. There is a sexual reproduction of greater complexity than in the other groups, and an asexual reproduction by means of tetraspores. The details of the reproduction serve to divide the Florideae into more or less natural groups. The tetraspores arise from single cells, which divide into four spores which are arranged characteristically in the different genera, in a tetrahedron (triangular), or side by side in a column (zonate) or in a plane separated by two partitions at right angles (cruciate). The Red algae present a great variety of contours and are often objects of great beauty; they provide food supplies for marine animals but are of little use to man.

Porphyra lives on the rocks at the border of low tide. Its fronds are shaped much like those of *Ulva.* They are of an olive-green colour when growing, but turn purple when dried. *Gala-*

raura is tropical and subtropical. The fronds are dichotomous and consist of chains of oval or oblong cells, compressed at the joints and usually incrusted with carbonate of lime. Hence the weeds look like coarse corallines. In *Wrangelia*, on the other hand, the fronds are graceful branching filaments of a beautiful feathery form and of various shades of red or purple. The fruits (cystocarps) appear at the tips of the branches as clusters of free spores surrounded by a whorl of terminal filaments. Australia is the principal seat of the genus. The stiff, bushy species of *Gelidium* would probably yield a useful vegetable gelatin.

Some of the kinds of *Iridaea, Gigartina* and *Kalymenia* form wide red or purple laminae of considerable size, very conspicuous objects in the heaps of storm-tossed weed, but growing in deep water beyond the reach of ordinary collectors. *Callophyllis* and *Rhodophyllis* form also beautiful fronds, often flattened, much-branched or dissected in our plants. *Rhabdonia* is an extensive genus with many filiform (stringy) branches, mainly Australian, with two or three outlying species. *Catenella, Bostrychia* and *Caloglossa* are small wiry plants, which often grow above high-water mark in bays, where they are only occasionally moistened by the spray. There are several species of the widely distributed genera *Gracilaria, Hypnea* and *Rhodymenia*. *Erythrocolon* is dichotomous with strings of shining ovate, red bead-like segments of considerable size. *Plocamium* (fig. 2) has its centre in southern seas and has several Australian species. The fronds are slender and much-branched, finally pinnate (the pinnae alternate in pairs, threes or fives) and are among the favourites of collectors. *P. hamatum*, with recurved hooks among the branches, occurs on Norfolk Island and on the opposite shores of Queensland, but all the other *Plocamia* live south of this latitude.

Among the Delesseriaceae are glorious species of *Martensia* (fig. 5), *Nitophyllum* and *Hypoglossum* (fig. 4), but *Claudea elegans* (fig. 8) is probably the most gorgeous of our seaweeds. Harvey called it the most beautiful alga of the world. The frond consists of a stout axis growing in the shape of a sickle and having on its convex side a lamina made up of an open network, 10 to 12 inches long and an inch across. From the concave side of the axis branches arise which grow into plumes similar to the original, while from the concave edges of these branches other smaller plumelets spring in their turn, the whole plant presenting a striking design of a compound feather with a bold sweep to one side. Cystocarps and tetraspores are produced in the crossbars of the network. *Claudea* is found in the Tamar estuary, in Western Port in Victoria, and more rarely in Western Australia.

Among the many other attractive Florideae we may specify the family Rhodomelaceae, with many endemic forms, such as *Dictymenia* and *Lenormandia*, besides a great many kinds of *Polysiphonia* and *Dasya* and their allies. In *Polysiphonia* the joints of the filamentous axis are made up of cylindrical cells placed side by side, and giving a striped appearance to the stem. *Dasya* (fig. 7) presents rich deep red plumes, most graceful in the water. The genus has its headquarters in Australia. The Rhodomelaceae are of a darker red than most other families; the cystocarps are urn-shaped and the tetraspores are borne in flat strap-shaped stichidia.

The Ceramiaceae include many of our most delicate seaweeds. They are much-branched, with fine rami and ramuli of a bright red colour, and often grow as epiphytes on larger algae. The ultimate ramuli at least consist of single cells growing in line, and when fertile bear cystocarps and tetraspores, and present a fairy-like structure under the microscope. The oospores are surrounded by a transparent envelope, not naked as in *Wrangelia*. The tetraspores have also a transparent envelope in which they are included. The most common genera are *Griffithsia, Callithamnion, Spongoclonium, Antithamnion, Spyridia* and *Ceramium*.

Lastly we may mention the Corallines which are so abundant on the rocks near low-water mark, *Amphiroa, Cheilosporum, Jania* and *Corallina*. They secrete carbonate of lime, and when dry become bleached and brittle, but are of a beautiful rosy colour when growing vigorously in their boisterous habitat.

Most of the Australian seaweeds are endemic. A very few, such as *Ulva lactuca, Enteromorpha intestinalis, Codium tomentosum, Plocamium coccinceum, Dictyota dichotoma, Champia parvifolia* and *Corallina officinalis* are found abundantly in the seas of the northern hemisphere. The isolation of Australia has been so prolonged as to have given time for differentiation of species and genera on a large scale, and the development of such marked forms as *Claudea, Cliftonaea, Notheia, Bellotia* and *Encyothalia*. Climate (i.e. the mean temperature of the water) seems to be the main factor determining the present distribution. The bulk of the species seem to have originated in the south, occupying Tasmania, finding a paradise in Bass Strait, and spreading east and west along the Australian coasts. Some, as *Delisea pulchra*, have travelled both ways, dying out as they approach the warmer subtropical waters; but mostly the eastern and western species are not identical. The northern shores have, on the other hand, been populated from the sea to the north of them. Quite a number of species are common to Malaysia, northern Australia and Polynesia. Some of them, as the forms of *Eu-Sargassum*, dwindle and disappear as they approach colder waters. At about the latitude of Caloundra, in Queensland (27° S. lat.), we find adventurers from both south and north meeting, and neither seem able to pass much beyond this point. Curiously, in Botany Bay, we find *Hypoglossum serrulatum* and *Gracilaria textorii*. The former is only known from this locality and Japan. The latter had been supposed to be confined to Japan. These are remarkable as giving direct evidence that there has been a migration from some northern region into Australian waters.

A.H.S.L.

Allen, George (1800-1877), son of Dr. Richard Allen, physician to George III., was born in London in November 1800. He arrived in Sydney in January 1816, served his articles with Frederick Garling, crown solicitor and clerk of the peace, and was enrolled as a solicitor on 22 July 1822—the first to be admitted by the supreme court of the colony. An attempt was made to exclude him from practising, but the judges held that he had equal rights with attorneys admitted by the English and Irish courts. In 1842 he was elected an alderman of the first Sydney municipal council, and in 1845 was its mayor. In July of that year he was nominated to a seat in the legislative council of the colony, which he held until its abolition in 1856; he was then nominated to the new legislative council for a period of five years, and at its expiration became a life-member of the council, resigning in 1873. From 1856 to 1873 he was its chairman of

committees. He was all his life much interested in education. He helped to found the Sydney College, and sat on its governing body from 1828 to 1877; he was one of the first members of the denominational school board, and on its abolition by the public schools act of 1866 was appointed to the council of education, on which he sat until 1873; in 1859 he was elected to the senate of the university of Sydney, and held the position till his death. He was also a prominent member of the Wesleyan-Methodist body, for which he built a church at the Glebe. He died at his home, Toxteth Park, Sydney, on 3 November 1877.

Allen, Sir George Wigram (1824-1885), son of George Allen (q.v.) was born at Surry Hills in Sydney on 16 May 1824, educated at William Cape's school and at the Sydney College, articled in 1841 to his father, and in 1846 admitted a solicitor of the supreme court of New South Wales. Like his father, he took much interest in education. From 1853 to 1866 he was a commissioner of national education, and in 1873 succeeded his father on the council of education, as he did in 1878 on the university senate. He was also for many years a trustee of the Sydney grammar school. On 25 May 1860 he was nominated to the legislative council of the colony. He was a member for the Glebe in the legislative assembly from December 1869 until August 1883. When at the end of 1873 a department of justice and public instruction was created by Sir Henry Parkes, he was put in charge of it, and held the portfolio until the Parkes ministry resigned in February 1875. He then became speaker of the assembly, holding that office from March 1875 to November 1882. In 1870 he was elected president of the incorporated law institute of New South Wales. He was a vice-president of the royal commission for the Sydney international exhibition of 1879, and of the New South Wales commission for the Melbourne international exhibition of 1880. He died at Toxteth Park, Sydney, on 23 July 1885.

Allen, Sir Harry Brookes, born at Geelong in 1854, was educated at the university of Melbourne (M.B., 1876; M.D., 1878; B.S., 1879), where in 1881 he was elected lecturer, and in 1882 professor, of anatomy and pathology. In 1906 he took the separated chair of pathology, and held it until 1924; the museum of pathology at the university is of his creation. From 1898 to 1923 he was a member of the university council. In 1888-9 he presided over two royal commissions, one enquiring into the sanitation of Melbourne, the other (an intercolonial one) into the plague of rabbits in Australia. In 1890, during a visit to Europe, he persuaded the general medical council in England to recognize medical degrees conferred by the university of Melbourne. In 1908 he was president of the Australasian medical congress. When in 1912 Edinburgh gave him the LL.D. degree, the honour was explicitly stated to be due to his 'outstanding position in medical science and devotion to those public purposes for which Universities exist.' Serious illness compelled him to retire from active work in 1924. (Kt. Bach., 1914.)

W.A.O.

Alligators. See Crocodiles.

Allport, Morton (1830-1878), born at West Bromwich in Staffordshire, was brought by his parents to Tasmania in 1831, trained for the law, and admitted a solicitor in Hobart. His interest, however, was concentrated on natural history, and he made it his business to send to the best authorities in England or elsewhere specimens of every new fish he could procure. His preparation of a descriptive list of Tasmanian fishes was interrupted by a comparatively early death. He took a leading part in the introduction of salmon and trout (q.v.) into Tasmania; he also introduced the white waterlily, and that very doubtful blessing, the English perch, which luckily has not thriven so well in Tasmania as in some mainland waters. He died in 1878.

T.D.

Alpacas. In 1844 the British consul at Arica in Peru was requested to send 16 alpacas to England for Queen Victoria. The day after their exportation General Ygain (prefect of Tacna) stopped a consignment intended for Germany, appealed to the Lima government, and procured a decree of congress (April 1845) prohibiting the export of alpacas from all ports of Peru. Charles Ledger, who had lived in Peru since 1836, determined to get some alpacas out of the country for Australia; he therefore in 1848 rented an estate on the frontiers of Bolivia and Peru, and by 1851 had succeeded in forming a flock of more than 600. Leaving Valparaiso on 24 December 1852, he visited Victoria and New South Wales, where the importation of alpacas had already been publicly advocated—especially by Thomas Mort in 1850—and satisfied himself that the country from Twofold Bay northwards was admirably adapted for the alpaca. Returning to South America, he spent five years in accumulating in northern Argentina, mainly by smuggling them over the Bolivian border, more than 1000 llamas, alpacas, vicunas and crossbreds. The account of his operations reads like a romance; 200 of the flock were lost in one snowstorm; mules and donkeys were frozen to death; two shepherds fell over precipices, and more than 200 animals were lost by drinking the waters of a leech-infested lake in the Calchaquies valley. In July 1858 322 animals were shipped at Caldera in Chile on board the *Salvadora;* and on 28 November 276 animals were put ashore in Port Jackson and placed in the Domain. In April 1859 the flock numbered 292—46 male alpacas, pure-bred; 38 female alpacas, pure-bred; 9 alpaca lambs, born in the colony; 110 female llamas; 43 females cross-bred between alpaca and llama; 40 cross-bred lambs; 1 female and 4 male vicunas; 1 male llama, carrier. At the instance of Charles Cowper, then premier, the New South Wales government purchased this flock (which had very much improved since its arrival) for £15,000, and transferred it first to Liverpool and then (though Ledger reported that the Monaro country was most suitable) to Arthursleigh near Goulburn. Before leaving Liverpool about 200 were shorn; about 6 cwt. of wool was obtained (alpaca, llama and cross-bred) valued at from 15d. to 2s. 2d. per lb.; but the price obtained in the market only reached 9d. to 1s. 6d. per lb., as the staple was too short, due to too early clipping.

This, however, was not the first introduction of alpacas to Australia. The Victorian parliament in 1856 boldly asked the Queen for some from her flock, but was told that there were none left in England. Titus Salt of Bradford (the pioneer of the alpaca industry in England) sent two small consignments to South Australia—one flock of four to Adelaide in March 1857, consigned to his nephew Haigh of Port Lincoln, and two male and three female alpacas in July 1858 to Matthew Moorhouse of Riverton. Ten

animals (llamas and crossbreds) were also shipped to Sydney in June 1858 by G. A. Lloyd of London, and sent on to Moreton Bay, while 23 others from the same herd were shipped by Wilson, Westgarth, and others to Melbourne in February 1859, in which year also Ledger sent 19 from the flock in his charge to be tested at the Melbourne zoological garden. In 1861 the New South Wales flock had increased to 417, and the small Melbourne flock to 45, and in the Sydney exhibition of that year the most interesting exhibit, according to the press of the time, was 'a group of stuffed alpacas facing the entrance.' A similar exhibit (if not the same) was despatched to the London exhibition of 1862, and created great interest among English manufacturers. About this time, too, a Peruvian merchant obtained from his government a concession allowing him to ship 1500 alpacas to New South Wales. The first consignment, shipped by the *Julia Farmer* from Cobija (then the port of Bolivia—it is now in Chile), reached Sydney on 4 September 1863, but it seems also to have been the last. For alpacas were falling out of favour. The drought of 1862-3 killed off 200 of the government flock: Ledger quarrelled with his superior officers, and went back to South America: and the remainder of the flock was distributed among various landowners, who found that the animals, being larger than sheep, required more food than they did, whereas the hair, though valuable, was less so than merino wool. Further, scab had broken out in the flock, and even when in good health it required more looking after and humouring than sheep did: after all, the alpaca's natural habitat is from 14,000 to 16,000 feet above the sea, and acclimatization in the lower and warmer lands of Australia must have been a difficult task under the most favourable conditions. The industry therefore died out.

Alstonia, a small genus of the family Apocynaceae, consisting of trees or tall shrubs with a milky juice, dispersed over tropical Asia and Malaysia. The leaves occur in whorls of 3 or more; fruit a pair of narrow, cylindrical follicles, with numerous flat seeds attached by their sides, bearded with long hairs. The seven indigenous species all occur in eastern Australia. *A. constricta* (Bitter-bark or Fever-bark), ranging from New South Wales to Queensland, is a coastal plant in northern New South Wales, but extends to the arid interior. The wood is pale yellow. The thick yellowish-brown bark is intensely bitter, is valuable as a febrifuge and tonic, and is quoted in London drug-lists; a decoction is sometimes sold in Australia as 'bitters.' It is said to have been used by English brewers of pale ale, as it does not produce certain ill effects ascribed to hops. It tastes very like cinchona bark, and somewhat resembles in its properties both quinine and strychnine. It has been used in the earlier stages of typhoid fever with considerable success. A yellow dye of various shades is also obtained from the bark. *A. scholaris,* from northern Queensland (the Dita-bark of India), has proved a valuable remedy in chronic diarrhoea and the advanced stages of dysentery. Its light wood is used in Ceylon for making coffins. Planks of the timber, covered with sand, were formerly used as tracing-boards in Indian schools; hence the specific name.

Bitter-bark.

Alt, Baron Augustus Theodore Henry (1731-1815), born in 1731 of Hanoverian parents, after a distinguished career in the British army (ensign, 1755) served in France (1758) and Germany (1760), and at Gibraltar (1781) during the siege; helped to raise the Manchester Volunteers in 1777 and three Swiss chasseur regiments for the East India Company's service in 1781; was appointed surveyor of lands for New South Wales under Governor Phillip—possibly because he had been an engineer of roads in the Scottish Highlands in 1763—and accompanied Phillip in the First Fleet. He laid out the settlements at Sydney and Parramatta, and surveyed most of the earlier land-grants; but age and constant ill-health soon incapacitated him from active work. As early as 1791 he was applying to be relieved of his post; in 1797 he retired from active duty, and in 1802 was officially retired on half-pay. The rest of his life was spent at Parramatta, where he died on 9 January 1815. His monument, with an inscription full of biographical details, is in the Anglican cemetery of that town. Its statement that Alt was at the battle of Minden (1759) seems to be incorrect, as he himself states (*H.R.N.S.W.* iv. 347) that he went to Germany in 1760. His title of baron derives from Hesse-Cassel.

Alunite, a hydrous sulphate of aluminium and potassium, valuable both for its alum contents and

as a source of potassium sulphate to be employed in fertilizers. Australian alunites always contain a proportion of sodium, and rather more water than the European and American types. Probably the most remarkable deposit of this mineral known to exist is at Bullahdelah in New South Wales, where it composes a large part of a low ridge, and has been sometimes described as a 'mountain' of alunite. The bulk of the ridge is, however, of such poor quality as to be commercially worthless, and the high-grade ore has to be hand-picked. The mineral is quarried, and the best quality exported to Runcorn in Cheshire to be converted into alum and aluminium sulphate; but the manurial value of its potash contents makes it probable that a local industry will eventually be established to exploit them. In South Australia the mineral occurs at two places, Carrickalinga Head (40 miles south of Adelaide) and Warnertown near Port Pirie. At the former place the deposit is exceptionally pure and easily worked, and its product has been both used locally for the contained potash and exported for its alum. The Warnertown deposit has not yet been commercially developed. Deposits have been discovered in the North-east Coolgardie and Kalgoorlie areas but have not yet been exploited. From Bullahdelah between 1890 and 1922 55,000 tons were exported; the export from Australia for 1922 was only 280 tons, valued at £950.

Amaryllidaceae, a family of bulbous or fleshy-rooted plants, widely distributed and most abundant in dry, sunny countries. Seven genera, containing 26 species, are indigenous.

Doryanthes is an endemic genus of 2 species.

Darling Lily.

Giant Lily.

D. excelsa (Giant Lily, the Gymea of the Illawarra aborigines) bears a dense globular head of flowers, surrounded by a series of green floral bracts, on the top of a tall flower-stem rising from the centre of a tuft of leaves 3-4 feet long. It ranges coastally from Jervis Bay to Queensland. In *D. Palmeri* the flowers are not strictly terminal, but arranged in clusters on one side of the (usually) curved spike. The inner side of the flowers of *D. Palmeri* is almost pure white. It ranges from the northern rivers of New South Wales into Queensland. The leaves of these plants are a mass of fibre of great strength. Sir Thomas Mitchell (q.v.) obtained a medal at the Great Exhibition of 1851 for ropes manufactured from Gymea fibre.

The genus *Crinum* ranges over tropical and southern Africa and Asia; it consists of bulbous herbs with basal leaves (flat or channelled), the flower-stems rising from them and bearing a cluster of large showy white flowers. Eleven species are indigenous to Australia. *C. flaccidum* (Darling Lily) is a handsome plant that grows plentifully near the Darling River, but has a far wider range, extending from Western Australia through northern Australia to Queensland. The bulbs yield a fair proportion of arrowroot. *C. pedunculatum*, a larger and stronger-growing plant, is commonly cultivated in gardens. It ranges along the coasts of New South Wales and Queensland.

Amphibia. In a broad sense this word is sometimes applied to any air-breathing animal, such as the hippopotamus or the crocodile, which habitually enters water, but technically the Amphibia of to-day include only frogs, toads, newts, salamanders and their allies—cold-blooded animals in which there is a marked difference between the young and the adult. With a few exceptions, the young live in the water and breathe by gills, but are subsequently transformed to lung-breathing land animals; thus they are in several respects intermediate between fishes and reptiles. In Australia we have no representatives of the worm-like, limbless amphibians (Apoda), or of the tailed amphibians (Urodela) of which salamanders and newts are well-known members. There are, however, about 60 species of Anura (frogs and toads).

The typical frog is smooth-skinned, slender-bodied and long-legged; the toad is characteristically clumsy, with short legs, and a warty and usually dark-coloured skin. The variations in different families are so great, however, that distinctions cannot always be made. Certain relatives of the typical frogs are very toad-like, and some species of so-called toad families outwardly resemble frogs. Both frogs and toads are often spoken of as batrachians.

In Europe and America it has been noted that frogs have definite spawning times and regular breeding habits, but in Australia interesting adaptations to local climatic conditions have been recorded by J. J. Fletcher and others. Except in certain coastal species, the spawning season is not confined to a definite period of the year, but is largely dependent on the rainfall. It is possible to meet with frog-spawn during any month of the year, should climatic conditions be favourable. This adaptation to the irregular rainfall is particularly noticeable in inland districts. In time of drought several species of frogs are able to hibernate in burrows below the surface. Some species before retiring literally fill themselves with water, and are thus able to keep themselves alive for a lengthy period. When the drought breaks they reappear. Ova deposited by the females are fertilized by the males, and very soon tiny tadpoles are seen swimming in clay-pans which, several days before, were completely dry and seemed absolutely devoid of life.

Most female frogs deposit their ova in water, after being embraced (sometimes for several hours) by the male. At breeding times the male frog often has on its fingers rugosities which enable it to hold its partner tightly; their pressure apparently assists the female in voiding the ova, which come into contact with the seminal fluid of the male after expulsion. In many species the eggs are laid in masses, surrounded by a soft jelly. The embryo, when it emerges, mainly consists of a large head and body, without limbs. External gills are usually present in the early stages. A long tail is next developed; subsequently limbs bud out, the gills degenerate, and the tadpole rises occasionally to the surface to breathe by means of its lungs. The tail does not drop off, but is gradually absorbed from within. This process of development is subject to some variation in different species. The toadlets known as *Pseudophryne* deposit their ova, not in water, but in cavities under stones and debris in damp places. Should the weather be unfavourable, their development may be retarded—even for three months, according to Fletcher; this explains the sudden appearance of small tadpoles after heavy rain. Considering their small size, many frogs are capable of making a remarkably loud noise. The males of some species have a dilatable vocal sac, and when this is in use the region of the throat has a curiously distended appearance. Apparently the skin of many batrachians is sensitive to changes in the atmosphere, and their croaking is often regarded as a portent of rain.

Frogs have many enemies. They are devoured by rapacious birds, or fall victims to the common black and other snakes. When seized by a snake, a frog may puff itself out to an abnormal size to prevent being swallowed, but usually in vain. Further, some species are infested by the larvae of certain dipterous insects. Because of their insect-eating habits frogs and toads are decidedly useful. Certain species will make sudden hops in order to catch prey. Insects, should they come within reach, are generally caught by a quick forward movement of the tongue. Examination of stomach-contents shows that various insects are eaten; some toads also devour earthworms and snails; but it has been observed that tadpoles of common species of frog will not feed on the larvae of mosquitoes.

Remarkable stories have been told of frogs or toads said to have been found in holes, far below the surface, that have been exposed by quarrymen and others. Some of these stories may have a basis of fact, as certain species have a habit of creeping along crevices or down holes and burrowing for a short distance. It has been proved by actual experiment that toads will live for over a year when sealed up in a block of limestone; when left for two years they were found to be dead.

Australian frogs and toads may be divided into five distinct families:—Ranidae, typical frogs; Engystomatidae, the so-called narrow-mouthed toads or frogs; Cystignathidae (or Leptodactylidae), including several burrowing

Fig. 1.

frogs; Bufonidae, typical toads; and Hylidae, including the tree-frogs. The distinctions between these families are based on structural details, which cannot be comprehensively dealt with here. It may be noted, however, that in

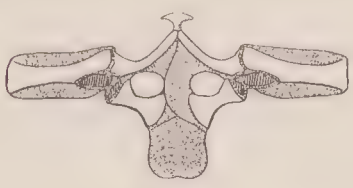

Fig. 2.

the first two families the cartilages which terminate the coracoids in the pectoral girdle are relatively small, and firmly unite in a median bar (Fig. 1). This is called the 'firmisternal'

type. In the remaining three families the terminal cartilages are more developed, and overlap each other (usually right over left); this type is called 'arciferous' (Fig. 2). When the skulls of Ranidae, Cystignathidae and Hylidae are examined, a row of tiny teeth may be seen on the upper jaws; and most frogs have short series of teeth on the borders of the vomers, which are small bones in the roof of the mouth. In 1922 G. K. Noble gave important reasons for merging the Cystignathidae into the Bufonidae.

Only two species of Ranidae have been recorded in Australia—*Rana papua*, a large frog from the Cape York Peninsula, which is also found in Papua and the islands of Torres Straits, and is probably an immigrant from the north; and *Rana daemeli*, which has the same distribution. In 1912 the late D. B. Fry described three species of Engystomatidae from northern Queensland under the generic name of *Austrochaperina*. This was the first record of members of this family in Australia, although they were known to be abundant in Papua. These frogs are said to feed on termites. In the Cystignathidae we have a number of common frogs, some of more than passing interest. The Great Barred River Frog (*Mixophyes fasciolatus*), found on the eastern coastal regions of New South Wales and southern Queensland, is our largest frog, the head and body together measuring up to four inches, and the hind-legs to nearly twice as long. The legs are marked with black bars. There is a dark band above on the snout; this seems to provide protective coloration when the frog is hiding, with only the top of its head exposed among debris in shallow pools by the edges of mountain creeks. There are nine species of *Limnodynastes*, some of which are very handsome, with dark markings on the back and the legs; one bears the specific name of *ornatus*. *L. tasmaniensis* and *peroni* are well-known forms.

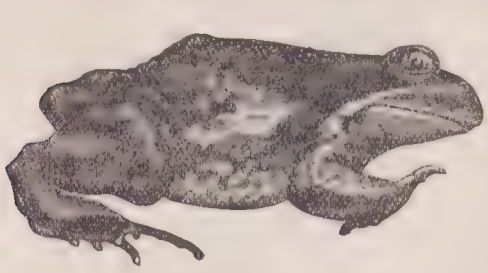

Fig. 3.
Limnodynastes dorsalis.

L. dorsalis is a very common frog, found from Cape York to Tasmania, as well as from east to west (Fig. 3); several varieties have been described. A light vertebral line is often present on the back of this frog. McCoy states that it feeds at night on spiders; and it has been known to devour a small frog of a distinct kind. In common with several other members of this family, it is a burrower, and is often dug up from the ground. The most remarkable burrowing species is the Water-holding Frog (*Chiroleptes platycephalus*), the habits of which have been described by Sir Baldwin Spencer. When found below the surface of clay-pans in the central districts in times of drought, the frog is sometimes swollen almost to a spherical shape with water swallowed before hibernating. The aborigines eagerly search for these frogs in order to secure the water. During a drought they are dull-coloured, but in the rainy season are alert and marked above with yellow and light green mottlings. In burrowing frogs a strong shovel-like tubercle is usually developed on the inner side of the metatarsals of the hind foot. *Helioporus pictus* is a smaller frog with similar habits, found near Melbourne, as well as in the central districts. On the eastern coastal regions *Adelotis* (*Cryptotis*) *brevis* is often common. The writer has frequently found it in open suburban drains, as well as on the hillsides. Looked at from above, this frog (or toad) would be considered very ugly; but its lower surface is highly-coloured, with deep orange and black-and-white markings. The genus *Crinia* contains a number of small species, some found under logs and stones. The active little Brown Froglet (*C. signifera*) is often common about Melbourne and Sydney.

The typical toads (Bufonidae) are almost cosmopolitan, but the genus *Bufo* is not represented in Australia. A curious member of this family is the so-called Catholic Frog or Holy Cross Toad (*Notaden bennetti*), on whose back a somewhat irregular cross is formed by a series of black raised warts on a greenish background, with orange and whitish spots; the coloration is probably of the warning type. This frog is known to feed on white ants. It grows to about one inch and a half in length, and when handled gives off an unpleasant yellow secretion, which renders it objectionable. *Pseudophryne* includes several species of toadlets; the commonest is *P. bibroni*, found under logs and stones in New South Wales, Victoria, Tasmania and Queensland. The upper surface is warty, the body marbled below with black and light markings. This toadlet has the habit of pretending to be dead when placed on its back. Reference has already been made to its special breeding habits.

There are over 20 species of Hylidae. Although this family is known as tree-frogs, by no means all our species are arboreal. In typical species the fingers and toes end in prominent circular disks, which are useful as adhesive pads. The giant of the family, a frog found at Hayti, has disks about the size of a threepenny piece. Many of our frogs are protectively coloured, wearing a shade of green which corresponds with their usual environment. Some show remarkable variations in colour. We have seen specimens of *Hyla peroni* which were quite stone-grey above when settled on a light material; when moved, they assume a brownish-olive tint. This species, which is not so large as the common green tree-frog, has a very harsh croak; it has the habit of hiding in the recesses of hollow posts.

Two large *Hyla* species frequently met with are *H. caerulea*, the common Green Frog, and *H. aurea*, the Green-and-gold Bell-frog. The former is a large species, with extensive webs between both fingers and toes; it was named *caerulea* because specimens preserved in spirit showed a bluish tint, but in life it is light green above, often with white spots on the sides. In Queensland this frog is common in gardens, and at night often enters houses and becomes quite tame if not molested. It is fond of cockroaches. Sometimes it travels up drainpipes, and reveals its presence by loud and persistent croaking. *H. aurea* is typically found near swamps, and is a powerful swimmer. Some specimens are beautifully marked with green, gold, blue and white. When about to hibernate, it may be almost black. Its fingers, unlike those of *H. caerulea*, are free from webbing. Apparently it does not extend

to the northern parts of Australia. The males have two vocal sacs, which distend at each side. They are said to devour small frogs in preference to insects.

H. ewingi is a widely distributed and very variable frog, and specimens have been obtained even near the summit of Mount Kosciusko. Sometimes it is quite white, and varies from this to dark brown. Many *Hyla* species are very slender in form, with pointed heads, and the disks terminating the fingers are small. One of these, *H. nasuta*, is a light olive-brown frog with raised longitudinal markings on the back, a blackish band on each side of the head, and the thighs marked with a black band edged with yellow. *Hylella bicolor* (sometimes called *Hyla fallax*) is a tiny frog sometimes seen in the reeds surrounding pools of water, but so protectively coloured, and so compactly settled on the reeds, that a casual glance may not discover it. It has also the power of assuming distinct tints. The Hylidae and Cystignathidae are numerously represented in South America as well as in Australia, and their presence in both countries is often adduced as part of the evidence in support of a former Antarctic land connection.

A large number of frogs have been recorded from Papua, and the wet climate of that country evidently favours their development. Several are closely allied to, or identical with, certain Australian species, but the majority are related to oriental forms. *Hyla* is well represented; a common species bears the name *H. macgregori*, after the well-known administrator. The Engystomatidae are the most numerous, and there are several species of *Rana*. It is of interest to note that a giant form of the Ranidae is found in the Solomon Islands.

See G. A. Boulenger's *Catalogue of Batrachia Salientia* (1882) in British Museum Catalogues; H. A. Gadow's *Amphibia and Reptiles* (1901), vol. viii of the *Cambridge Natural Histories;* Lucas and Le Souef's *Animals of Australia* (1909); G. K. Noble's *Phylogeny of the Salientia* (1922); and papers by J. J. Fletcher in the *Proceedings* of the Linnean Society of N.S.W., and by D. B. Fry in the *Records of the Australian Museum.*

H.A.L.

Anacardiaceae, a family of trees or shrubs abundant in tropical (rare in temperate) regions, with six indigenous genera and 10 species; flowers small. *Rhodosphaera* (*Rhus* of von Mueller) *rhodanthema* (Yellow-wood) is a tree of 70-80 feet, with dense pyramidal sprays of small pink to crimson flowers, growing in the brush forests of northern New South Wales and Queensland. The wood is soft but durable, and takes a fine polish; an acid ingredient of the sap prevents it from burning easily. A yellow dye has been obtained from it. *Euroschinus* is an endemic genus limited to one species, *E. falcatus* (Maiden's Blush Wood), a large tree (140-150 feet) of the coastal brushes of New South Wales and Queensland, whose timber somewhat resembles cedar. The genus *Spondias* is chiefly tropical. *S. Solandri*, found in north-eastern Australia, is a tree of moderate size, with a hard rough timber. See SEMECARPUS.

Anchovy. An Australian anchovy (*Engraulis australis*) is so similar to the European species as to be distinguishable only with difficulty. It occasionally occurs in enormous shoals off the coasts of New South Wales, Victoria, and Tasmania, and its range extends to south-western Australia, southern Queensland and New Zealand. Though abundant at certain seasons each year, it is not utilized commercially. A number of tropical fishes of the genus *Stolephorus*, allied to the anchovy, have been found in Australian waters, but little is recorded of their occurrence. They differ from the typical anchovy in having a firm skeleton, and are therefore less valuable than the southern species. A.R.McC.

Anderson, JOSEPH (1790-1877), born in Sutherlandshire, Scotland, on 1 June 1790, at the age of 15 entered the army (ensign, 1805; lieutenant, 1808; captain, 1821; major, 1826; lieutenant-colonel, 1841) and served in Italy during the campaign of Maida (1806), in Egypt (1807), in the Peninsula (1808-12) and at the capture of Guadaloupe (1815). In 1826 he became a major in the 50th foot, and sailed with his regiment for New South Wales in 1833, reaching Sydney on 2 March 1834. At the moment news had just been received from Norfolk Island that another of the many convict risings was in progress, and Anderson was hurried away within ten days of his arrival to act as commandant on the island. He took severe measures to restore order, and for the five years of his rule the island was orderly. Towards the end of his term the British parliament was giving much attention to the conditions under which transportation was being carried out, and Anderson's severity came in for condemnation—though Bourke specifically commended his 'humane but firm and vigilant superintendence.' Also, the type of convict sent to the island was altered—since 1826 it had been used for 'twice-convicted' prisoners (i.e. those who, coming as convicts to New South Wales, were again convicted in the colony of serious crime), but in 1839 it was decided that convicts under an English sentence should be sent straight to the island. It was therefore decided to replace Anderson with Alexander Maconochie (q.v.), an advocate of very mild discipline; but, as Anderson's regiment was being recalled in 1839 for service in India, he was at once relieved by the temporary appointment of Major Bunbury, Maconochie taking up his duties some time later. Returning to active service in India, Anderson gained distinction at the siege of Gwalior in 1843. In 1848 he retired on half-pay and migrated to Victoria; there he was in 1852-6 a member of the nominee legislative council, and for many years after maintained an active interest in questions of defence and of Chinese immigration. He lived for nearly 30 years on Punt Hill, South Yarra, and gave his name to a street there. He died on 18 July 1877. (K.H., 1838; C.B., 1843.)

See his *Recollections of a Peninsular Veteran*, posthumously published in 1913.

Angas, GEORGE FIFE (1789-1879), youngest son of Caleb Angas, coach manufacturer and shipowner, was born at Newcastle-on-Tyne on 1 May 1789, apprenticed to his father's business in 1804, and made a partner in it about five years later. In 1824 he started a branch of the shipping business in London, which in 1826 became an independent firm; but in 1831 the whole of his father's business again fell into his hands, except the coach factory, which had been taken over by an elder brother. In 1832 Angas was approached by the founders of the South Australian Land Company, and—influenced by his study of the life of William Penn—became a member of its provisional committee. This company failed to win government approval; when, however, two years afterwards the

South Australian Association (see SOUTH AUSTRALIA) was formed, Angas joined the board of commissioners, and it was almost entirely by his personal exertions that the subsidiary company's capital was raised. Becoming a director of the company, he resigned his commissionership, and again by his personal and active persistence succeeded in despatching to Australia on 22 February 1836 the first shipment of settlers. In the same year he helped to found the South Australian School Society to provide education for the settlers' families. The subsequent financial troubles in which the new colony became involved made it necessary to send his son, John Howard Angas, to South Australia in 1841; and in 1850, although two years earlier he had found himself compelled to resign his seat on the board of directors, he decided to migrate to and settle in South Australia. It is noteworthy that the date of his departure was approximately fixed by the passing, on 5 July 1850, of the act that gave a constitution to the colonies of Australia; 'now that the Bill has passed' he wrote in his diary, 'I feel that my work is done here, at least as regards South Australia.' Travelling by the *Ascendant*, which also took to the colony the official copy of the constitution act, he reached Adelaide in January 1851.

Once in the colony, he settled at Angaston in the Barossa district, which had already been greatly developed by J. H. Angas. In August 1851 the district returned him unopposed as its first representative in the legislative council; and he retained his seat there, and in the council of the bi-cameral legislature that succeeded it, until 1866, when he retired from practically all active public life, though maintaining control of his private business and interest in public affairs until his death. He died at Angaston on 15 May 1879.

So far nothing has been said of his numerous philanthropic activities—beginning with the Benevolent Society of Coachmakers which he originated in 1807, before he was of age, and ending with the Angaston Recreation Park which he opened at the end of 1878—or of his many public (and especially financial) achievements. The following is a mere catalogue of the more important work coming under each head. Always a firm supporter of Christian missions, his interest in the mahogany trade of Honduras led him in the early twenties to join Wilberforce and Zachary Macaulay in attacks on West Indian slavery; a few years later he became interested in missions to the Hindus also, and in the thirties sent out Lutheran missionaries to the aborigines of South Australia. Early in 1836 he met Augustus Kavel (q.v.), a representative of certain Lutheran congregations in Prussia who were at odds with the Prussian government about the use of a new liturgy, and were being treated intolerantly. Migration seemed the only remedy; and in 1838 300 of them sailed for South Australia in the *Prince George* and *Bengalee*, another 200 following in the *Zebra* and 120 more in the *Catherine*—all vessels provided by Angas and largely equipped at his expense. (The further history of these German migrations to South Australia is narrated under KAVEL, AUGUSTUS.) He also, after many years of planning, helped in 1832 to found the British and Foreign Sailors' Society.

His public life was concerned mainly, though not altogether, with finance. He was a co-founder of the National Provincial Bank of England (1833), the Union Bank of Australia (1837), and the Bank of South Australia (1841). In December 1838 he obtained for the colonial office the information about French designs on New Zealand that hurried on British annexation (see NEW ZEALAND)—for this service he was offered first a knighthood and then a baronetcy, but declined both. He played an important, though inconspicuous, part in the shaping of the South Australian constitution of 1850, being largely responsible both for the omission of clauses which would have established a form of federation and for the recognition of the principle that no state aid should be given to religious bodies. When established in South Australia he became a very active influence in local politics, successfully advocating high-priced land, the increased immigration of skilled labourers, and an elected upper house, while he opposed (without success) the introduction of railways, voting by ballot, and the annexation of the Northern Territory.

See Hodder's *Life of George Fife Angas* and Harcus's *South Australia.*

Angas, GEORGE FRENCH (1822-1886), eldest son of George Fife Angas (q.v.), born at Newcastle-upon-Tyne on 25 April 1822, was educated at Tavistock and intended for business pursuits. Disliking these, he studied lithography and anatomical drawing, and in 1843 went to South Australia and accompanied Sir George Grey (then governor) in many up-country expeditions, sketching the scenery, aborigines, and flora and fauna of the country traversed. Proceeding to New Zealand—which was then very little known beyond the coast-line—he similarly sketched the inland districts of those islands, and on his return to England in 1846 set about the publication of *The New Zealanders Illustrated* and *South Australia Illustrated*, both books appearing in 1847—as did a third, *Savage Life and Scenes in Australia and New Zealand.* Meanwhile he visited South Africa and obtained material for a fourth book (*The Kaffirs Illustrated*, 1849). In that year he revisited South Australia, and in 1850 made sketches of life at the gold-diggings of Ophir in New South Wales, which were published in London in 1851. In 1853 he was appointed secretary of the Australian Museum, Sydney, and held the position for six years. In 1861 he returned to England, where he spent the remainder of his life; during this time he illustrated McDouall Stuart's and John Forrest's accounts of their explorations in Australia, and wrote much both for popular and for scientific journals. He died in London on 8 October 1886.

A younger brother, JOHN HOWARD ANGAS (born on 5 October 1823), has been already mentioned as assisting his father, G. Fife Angas, in managing his South Australian businesses. Starting independently in 1853, he soon became known as a stockbreeder. He represented Barossa in the legislative assembly from 1871 to 1875, and later was elected to the council. He was a generous benefactor to the university of Adelaide, to many South Australian charities, and to Dr. Barnardo's Homes, and was a founder of the Bushmen's Club in Adelaide, president of the British and Foreign Sailors' Society (which his father had founded), and originator of the Angas Industrial Mission to New Guinea. He died on 17 May 1904.

Angel-sharks or MONK-FISH, members of the family Squatinidae, a group which is transitional between sharks and rays. The body is depressed and flat like that of a ray, and the greatly enlarged pectoral fins form an im-

perfect disk; but they are separated from the head, instead of being united with it, as in rays. Further, the gill-openings are on the side of the neck, as in sharks, instead of on the lower surface. Several species are known from temperate seas; the commonest Australian form is *Squatina australis*, which occurs in shallow waters south of the tropics, and attains a length of five feet. Another Australian species, *S. tergocellata*, is known from a single small specimen trawled in deep water in the Great Australian Bight.

Angling. Under this head are discussed (*a*) sea-fishing with rod and line, (*b*) sea-fishing with hand-line, (*c*) river-fishing with rod and line.

The lack of knowledge about game-fish angling in Australia may be accounted for by the fact that few anglers have tested the possibilities of the sport in any but a superficial way. Rod-fishing in salt water has become popular only in recent years, and even now hand-lining has a great many followers. The most important 'game fish' in Australian waters are swordfish (caught off the coast of Queensland) Spanish mackerel, kingfish, bonito, tunny, and albacore, distributed along the coast from Broome south-about to Townsville. Moreton Bay and Port Stephens have been exploited more than other places; Spanish mackerel and kingfish are frequently caught there up to about 30 lb. in weight, and much bigger fish have been hooked and lost. The best bait for these 'game fish' is a fresh garfish, placed whole on the hook and wire trace, so as to swim naturally, without spinning, when trolled. For jewfish (running up to 80 lb.), black rock cod (400 lb.), sharks 12 feet and over in length, rays, and groper, dead fish-bait is the best. The smaller kingfish, tailor, barracouta, Australian salmon, and at times flathead and snapper, take a metal spoon or spinner readily, and afford good sport on light rod and tackle. For bigger 'game fish' anglers should be equipped with the kind of tackle used on the coast of North America or New Zealand.

The beaches of the Australian coast seem made for the angler, with clean, hard, tawny sand, tides rising about five feet, and pockets of blue water where the waves create an eddy. The fishing is usually best in the neighbourhood of inlets or estuaries. A cast of 30 yards should reach fish. The tackle recommended is a greenheart or built-cane rod about 10 feet long, 15 oz. in weight; a Nottingham Malloch, or multiplying reel; Japanese gut, or silk, line with thread backing; hooks to suit bait and fish; sinkers, ½ oz. to 2 oz. This tackle is suitable for whiting, trevally, sea bream running from half a pound to 4 lb. or over, jewfish, and salmon; these give the most popular sport on beaches and at river entrances. The baits used are pippies, beach-worms, prawns, crabs, and mullet or other fish-bait.

When fishing near rocks or reefs whether from shore or boat, the angler may catch snapper and groper up to 25 lb. in weight, silver drummer, blackfish, morwong, pike, and other species. Ledgering from a boat in estuaries and tidal rivers is fascinating sport among the smaller fish already mentioned. The boat must be moored stem and stern, and kept steady. Two men can use two rods each; the finer the tackle, the better the results. Float-fishing off rocks or in harbours and rivers is very popular. Skill, berley (ground bait), and cunning are needed to catch the larger bream (known as black bream and silver bream); baits already mentioned may be used. Blackfish and drummer may be enticed with 'green weed,' a kind of sea-grass that grows on piles or rocks; 'cabbage,' a seaweed which grows in little tufts on the rocks, is also used, and cunjevoi. In quiet water a quill float is best; but along an ocean coast or on rough sea-walls a long cork float is used, weighted for casting. Small hooks are needed. The tackle must be fine and strong, as both fish are determined fighters and give splendid sport on a light rod. Ebb-tide is the best period for this kind of fishing, which is the most popular form of float fishing, and would have delighted contemplative old Isaac Walton.

To those who like the 'pull devil pull baker' style of fishing, the natural bamboo pole and strong line, with or without reel, may appeal. The many sea-walls at river inlets along the north coast provide suitable hunting grounds, where with well-weighted line, and bait allowed to be still, fine bream and occasional groper and drummer are caught on small rock crabs, mullet, or other baits. A fine wire leader is almost indispensable, and the fish should be given short shift.

Sport in Tasmanian coastal waters is like that on the Australian coast, with a little variation in the fishes.

Hand-lining hardly comes within the category of angling, but must be mentioned, as it is used considerably on almost all salt-water fish. 'Black-breaming' with a fine gut line in the quiet waters of inlets is an art which requires much skill, patience, and quietness. It is best learnt by practice under experts. A dark night and a rising (or full) tide is best for this work; the swim should be well berleyed with pollard and herring or the like. Several dozen fish averaging 1½ lb. may be taken in this way. Drifting in a boat is another method of fishing for whiting, flathead, flounder, and other fish.

The most favourable months for salt-water fishing are, generally speaking, November to May (summer); the worst are August, September and October (late winter); but throughout the winter blackfish descend from the estuaries to ocean rocks, and are angled for there. Bream and tailor may be caught on ocean beaches, in the colder months, especially at night. Snapper, squire, and red bream (the same fish at different ages) are caught at that time of the year in the outer waters.

In all the States sea-fishing is controlled by government departments. Net fishermen are subject to restrictions as regards size and mesh of nets, close seasons, and sizes of fish that may be caught, but only the last-mentioned applies to line-fishing in salt waters. Besides beaches, rocks, estuaries, and sea-walls, the salt-water lagoons are attractive ground for the angler.

Atlantic salmon ova were successfully hatched out in Australia in the forties; the fry, however, never thrived. Brown trout hatched out about the same time were the original stock of our present brown trout. In Tasmania they have occasionally attained, in the Great Lake, the weight of 25 lb. Rainbow trout have been caught up to 15 lb. Lake Leake records trout of 10 lb., but the average weight is 3¾ lb. On the mainland brown and Loch Leven trout were first angled for in the Snowy River about 1900. Brown trout have held their own in many rivers of New South Wales, Victoria, and Tasmania,

though the advent of the rainbow trout (introduced from America via New Zealand about 1886) for a time eclipsed the popularity of the brown trout. The recent reaction in favour of brown trout is very marked in Victoria, where the idea had become prevalent that the two fish do not thrive in the same waters—on account of their different time of spawning, the one fish is said to prey on the ova of the other. As a matter of fact, in the Snowy, Murrumbidgee, Eucumbene, and Mowamba (all rivers of New South Wales) the two have thriven together for over 20 years; each seeks out, and remains in, the water most suited to its habits. Where the two fish are together the more vigorous rainbow frequents the rougher and cooler waters, while the brown trout occupies quiet swims and warmer backwaters—so much so that experienced anglers may to some extent select the species they wish to take. But this does not obtain in all waters, for rainbows only are found in many New South Wales streams, and only brown trout in some waters of Victoria and Tasmania. Loch Leven trout have also been introduced into some rivers and lakes, but frequently appear to have lost their characteristics and to have reverted to, or crossed with brown trout, here, as in New Zealand. American black-spotted trout and salmon-trout fry have been liberated in some streams, but have quite failed to establish themselves. In Tasmania a trout (probably the brown) descends to the estuaries. Rainbow trout have been caught in Australia up to 12 lb. in weight, but there is no authentic record of brown trout of that weight. In individual fish the rainbows top the scales, especially in slow streams such as the Bigbadja (New South Wales) or in some streams when they are first introduced, such as the tributaries of the Murray River. In the Snowy River though there is on record a rainbow of 9 lb. 2 oz., one of 5 lb. is now a rare fish, and a brown trout of 4 lb. unusual; yet the average brown trout is heavier than the average rainbow, and is a less capricious fly-taker though a less vigorous fighter. The average fish caught weighs about one pound. Trout also thrive in lakes in Tasmania, Victoria, and New South Wales—e.g. the Great Lake and Lake Leake in Tasmania; Wendourie and Katani in Victoria; the Burrinjuck dam and dams near Kiandra in New South Wales. The principal trout rivers are the Mersey, Ouse, Derwent, Esk, Dee, and Shannon in Tasmania; Gippsland streams, Delatite, and Ovens in Victoria; the tributaries of the Murray on the borders of Victoria and New South Wales, and the Snowy, Murrumbidgee, Tumut, upper reaches of the Macleay, Macquarie, Barrington, Hastings, and Manning in New South Wales with their tributaries; also streams in the Federal Territory (Canberra), and wherever the altitude is over 2000 feet in the Monaro and New England districts.

Sebago and quinnat salmon have been introduced into the Tasmanian lakes recently, but it is too early to pronounce on the result. Tasmania imposes on anglers a licence-fee of 10s. per annum for trout-fishing; in Australia no licence is required. The close season in New South Wales lasts from 14 April to 30 October, varying slightly in Victoria and Tasmania. There are a few trout in small streams near Adelaide (South Australia), but in no other States. Attempts at acclimatization in Queensland were a failure.

Flies or minnows used for trout in England and elsewhere will answer just as well in Australia—'silver doctor,' 'Jock Scott,' 'Wilkinson's,' and the like for the larger fish; 'March brown,' 'coch-y-bouddu,' 'governor's,' 'Hoffland's fancy,' 'Invicta,' the palmers, duns and spinners, Irish lake-flies, etc., for trout of average size. One may fish with wet or floating fly according to fancy. Large trout are often caught with a sunk wet fly, worked as in the New Zealand lakes. English perch and tench have been introduced into some of the States.

Occasionally a snake is seen on the rivers, but there is no record of an angler having been bitten; still it is well to wear thick woollen or rubber wading stockings. The government tourist departments of the three States have under their control several good accommodation houses, notably on the Great Lake (Tasmania), at Mount Buffalo (Victoria), Kosciusko, The Creel, and Yarrangobilly (New South Wales). Elsewhere accommodation is obtained at hotels, farms, or camps—and for camping the climate of Australia is well suited.

Among freshwater fish indigenous to inland streams west of the dividing range which are worthy of the angler's attention are the Murray cod (occasionally caught over 80 lb.), Murray (golden) perch, Macquarie black perch, and silver perch; of the last three weights up to 4 lb. have been recorded, but the average is 2 lb. The first three are good table fish, but would hardly be deemed game fish. Cod readily take a large spoon bait, especially if it has a red tassel. Perch sometimes take artificial spinners; the Macquarie perch has been known to take a small trout-fly or halcyon spinner. Usually, however, these fish are taken with baits of various kinds—worms, frogs, meat, grubs, etc. Their river haunts are subject to prolonged droughts, but the fish survive in the pools, and on the advent of a flood or fresh very quickly spread themselves; it is then that the best sport may be looked for. They have great powers of recuperation, and breed prolifically. Professional fishermen make a living by trapping and hand-lining Murray cod and perch for market. In the rivers of northern Queensland there is a giant perch, often known as barramundi (q.v.). It is also caught in the brackish water of estuaries. It is a strong fighter, takes a spinner and gives excellent sport. The ceratodus (Burnett salmon) is caught only in the Burnett River in Queensland. In these rivers anglers must be wary of crocodiles. In the shorter rivers of New South Wales and Victoria, east of the dividing range, are fine perch (or bass), distinct from the perch of the inland rivers, and known to naturalists as *Percalates fluviatilis*. They occur also in the Gippsland lakes. These fish will take an artificial minnow or a spoon; but the best sport is to be had with a fly of the size used for salmon, such as a 'hornet,' 'Jock Scott,' or anything resembling an insect and kept moving. A rather stiff trout-fly rod and strong tackle should be used, as when hooked the perch bolts for the nearest log or rock. An average weight is about one pound, but fish of 6 lb. and over have been caught. In the rivers they prefer quiet eddies and backwaters.

Mullet are found in rivers inhabited by the perch just mentioned, and are caught with worms and dough. A mullet of two pounds and over puts up a great fight. A catfish is found in many coastal streams, but is prized more by the cook than the angler.

In addition to the foregoing freshwater fish, some saltwater fish (e.g. bream, tailor, and flat-

head) often penetrate a mile or two into the fresh water at the head of tidal waters; here perch may be caught with a fly and saltwater fish with baits. The much debated estuary perch, thought by some to be identical with *P. fluviatilis*, will not take a fly in salt water, and should be angled for with live shrimps or prawns. Eels are plentiful in the coastal streams, and run to a large size.

A freshwater herring abounds in some rivers, chiefly near tidal waters, and will rush at a small trout-fly; they sometimes reach a quarter of a pound in weight, but average about an ounce. Formerly cucumber mullet (*Chlorophthalmus nigripinnis*) were plentiful in Tasmanian and some Australian streams, but they have almost disappeared.

Acclimatization is controlled chiefly by the government fisheries departments in Australia and by fisheries associations in Tasmania. The tourist departments of the several States will supply information; for more detailed advice anglers should apply to the New South Wales Rod-Fishers' Society in Sydney, the Piscatorial Council in Melbourne, the Ballarat Anglers' Club, the Northern Tasmanian Fisheries Association, or other local angling clubs.

See T. C. Roughley's *Fishes of Australia*, A. R. McCulloch's *Fishes of New South Wales*, and H. Joseland's *Angling in Australia*. H.J.

Angophora, a genus of trees of the family Myrtaceae, endemic in the sandstone regions of eastern Australia, is closely allied to *Eucalyptus*, from which it is distinguished chiefly by the absence of the operculum. The calyx-tube is bell-shaped and 5-angled, the white margins of the lobes having the appearance of petals; stamens very numerous; fruit a 5-ribbed capsule. *A. lanceolata* (Smooth-barked Apple) and *A. intermedia* (Narrow-leaved Apple) yield a reddish-brown kino of a brittle nature. The timber of both species is liable to gum veins, but when free from these defects is useful, as it is hard, tough and impervious to damp, and therefore adaptable for naves and spokes of wheels, slabs and rough building material. *A. subvelutina* (Broad-leaved Apple) is lopped for stock in times of drought. Its timber is heavy and tough, takes a good polish, burns well, and contains a large proportion of potash. *A. cordifolia* (Dwarf Apple), a shrubby species with opposite leaves, heart-shaped at the base, and bristly fruits, is very ornamental. Its enormous umbels of creamy-white flowers, full of honey, attract a great variety of insects, and so yield a harvest to entomologists. *A. melanoxylon* is one of several trees known as 'coolabah,' q.v.

Dwarf Apple.

Anonaceae, a large family of trees, shrubs or woody climbers, chiefly tropical. The genus *Melodorum* has three indigenous species; *M. Leichhardtii* (Merangara of the aborigines) is a shrub with flexuous, almost climbing branches, dull-greenish flowers and oblong fruits. The berries are eaten raw by the aborigines. It ranges from northern New South Wales into Queensland. *Eupomatia* has two endemic species: *E. laurina* (Rosebush or Bolwarra), a soft-wooded shrub with glossy laurel-like leaves, has flowers with an exceptionally strong odour; this attracts certain very small weevils, whose visits bring about cross-pollination.

See the *Handbook for New South Wales* (published for the 1914 meeting of the British Association for the Advancement of Science), p. 389.

Antarctica. (This article deals mainly with the Australian share in Antarctic exploration.) Captain Cook associated Australia and Antarctica in history when during his second voyage, on 17 January 1773, he was the first to cross the Antarctic circle north of Enderby Land. Twelve months later he reached 71° 10' S. in a region where (as he himself foresaw) no explorer has yet gone farther. With his small sailing vessels Cook could not penetrate far into the icepack; but he conjectured that a large continent lay within it.

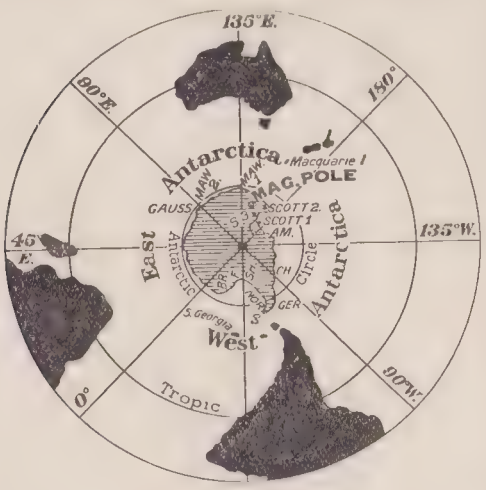
D'Urville, Wilkes, and Ross carried out explorations in 1840-2 on behalf of France, the United States and Britain respectively. They explored the coasts immediately south of Australia, the two former delineating a coast-line which was later extended by Mawson, while Ross sailed into the sea since named after him, and discovered the regions with which the names of Scott and Shackleton will always be associated. D'Urville and Ross also mapped the extension of Antarctica towards South America, where it stretches northwards to 63° S.—about as far from the equator as are the Faroe Isles in the Arctic.

For over 50 years little was done to increase our knowledge of Antarctic geography, though Neumayer urged the adventure from the time of his association (1856) with the Melbourne observatory, and his efforts led directly to the voyage of the *Gauss* in 1901. In 1894 the Norwegian whaler *Antartic* sailed south from Melbourne to prospect for whales, carrying as one of her crew C. E. Borchgrevink, who had spent some time in Australia and may therefore be described as having 'broken the ice' for Australian explorers. On 23 January 1895 a party

from this vessel (including the master and Borchgrevink) landed near Cape Adare, and were thus the first people to set foot on the Antarctic continent. In December 1898 Borchgrevink led an expedition in the *Southern Cross;* Louis Bernacchi, a young Tasmanian who had been trained in Melbourne, was his meteorologist. The ship landed a party of 10 at Cape Adare, where they built a hut and spent the winter of 1899. These men may be termed the first inhabitants of Antarctica; but, hemmed in by ice cliffs and open sea, they were unable to advance our knowledge greatly. In 1900 Borchgrevink landed on the Ross Barrier, and marched inland a short distance to 78° 50′ S.

In 1901 Commander R. F. Scott, R.N., was sent in the *Discovery* to carry on explorations in Victoria Land. The *Discovery* was especially fitted for a magnetic survey, and of this Bernacchi had charge. The German expedition under Drygalski simultaneously carried out observations at the Gaussberg far to the north-west. Scott traced the great Ross Barrier until its eastern boundary was approached at King Edward VII Land; then he returned to Ross Island, and for two years stationed his ship off the south-western slope of Mount Erebus. In November 1902 the first long sledge-journey in Antarctica was made by Scott, Shackleton and Wilson. They marched south over the Barrier for 300 miles along the base of a great range of mountains that rise at times to over 10,000 feet. In the spring Scott marched up the Ferrar and Taylor glaciers to the great inland plateau which is the characteristic feature of Antarctica. A thick carapace of ice covers the whole plateau, which rises in this latitude (78° S.) to about 8000 feet above sea-level. He reached a spot 300 miles west of his winter-quarters, having crossed the line joining the magnetic and south poles. Scott's expedition, therefore, explored the three major features of this sector of Antarctica—the great plateau, the huge outlet-glaciers, and the low-level expense of the Barrier ice.

It was now possible to estimate the general character of the new continent. In shape it closely resembles South America, and the two continents remind one of two pears placed in line with the stalks nearly touching. But



Antarctic Continent.

Antarctica is much smaller—probably about 3½ million square miles in area, or 20 per cent larger than Australia. A series of fold-mountains seems to carry the Andes into western Antarctica by way of the South Georgia loop. In the same way on its eastern side the block-fault mountains of eastern Australia are perhaps prolonged in the gigantic ranges that extend from Cape Adare almost to the Pole. The resemblance is yet more striking in that both these regions have their highlands on the coast, and the eastern scarp is much steeper than the gentle western slopes. In the Antarctic, however, instead of the low Australian western plains, there is the largest high plateau in the world. It seems to culminate near the South Pole at 11,000 feet, but falls to 8000 feet near Scott's headquarters, and to 4000 feet not far south of Mawson's headquarters.

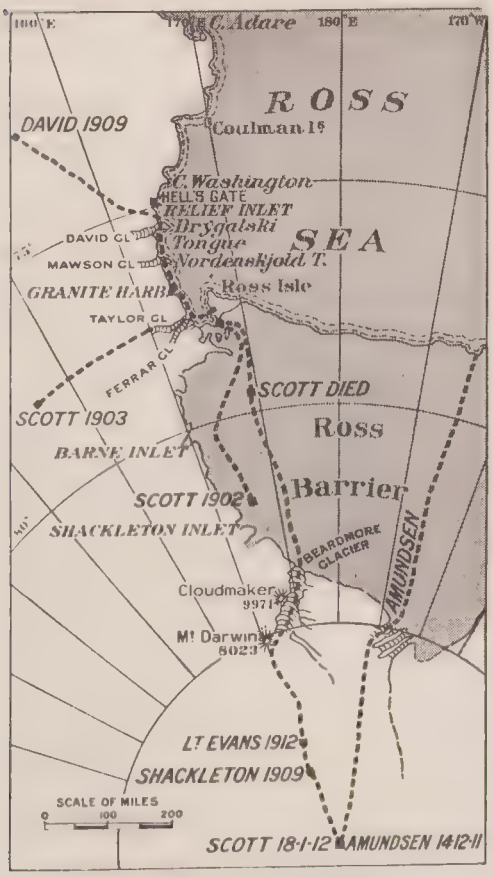
The geological formations of the Australian sector of Antarctica are akin to those of southern Australia. The basal gneisses resemble those of Eyre's Peninsula; the red and grey granites are also found in the southern States. The most southern fossils from the Beardmore glacier are Cambrian 'corals' like those of the Flinders Range, and Permian ferns allied to those of our Newcastle coal-measures. The Beacon sandstone—the chief sedimentary formation—may ultimately be shown to resemble in its later developments the late Palaeozoic and Mesozoic sandstones of Australia. Finally, the extensive dolerite 'sills,' which have penetrated thousands of square miles of sandstone, recall in many of their features the similar sills of Tasmania.

Biology seems to indicate that the old cartographers, in their delineation of a huge Antarctic continent, were only reproducing actual ancient conditions. Thus the flora and fauna of Tasmania have in some respects close affinities with South America. Geoffrey Smith writes of the temperate jungles of western Tasmania:—

> The xerophytic gums are almost everywhere replaced by evergreen myrtles or beeches, and the undergrowth attains a rankness and a density which have to be seen to be believed. There is an entire change of vegetation and scenery, so that one seems to pass right into, shall we say, Tierra del Fuego, or a lost Antarctic continent.

A genus of small coniferous shrubs (*Fitzroya*) has only two species, one confined to Tasmania and the other to South America; so also the Tasmanian wolf (*Thylacinus*) is almost identical with an extinct marsupial from Patagonia, whereas the whole of Asia (now much more readily accessible from Australia) has no recorded marsupials, living or fossil. The Antarctic land-connection, if it existed, has long vanished, but relics of it may persist in Macquarie Island and in the submarine ridge discovered by Captain Davis in 1912. When we know that the Himalayas have been elevated in comparatively recent geological times, it is easy to understand that Jeffreys Deep and the Southern Ocean generally may have developed in the same period. On the other hand most of these widespread genera go far back in geologic time; so that dispersion from a Mesozoic Asiatic centre possibly accounts for their present widespread distribution.

One of the most successful Antarctic expeditions was that led by Shackleton during 1907-8; and it is not too much to say that the Australians —Professor (now Sir) Edgeworth David and Dr. (now Sir) Douglas Mawson—shared with the leader the main honours of the struggle. Shackleton had hoped to land at King Edward VII Land, some 400 miles E. of Ross Island, but was compelled to build his hut on Cape Royds, some 20 miles N. of the *Discovery* station. In March 1908 Professor David and a party con-



Ross Sea and Barrier.

quered Mount Erebus, 13,370 feet above the sea and surrounded by the incomplete rings of three older craters, which in places project as black fangs from the white mantle of ice. At 11,000 feet they found a field of 'fumaroles,' whose steam built up huge cowls of snow and ice. On 10 March they reached the summit, and found an active crater 900 feet deep and half a mile wide. Steam explosions were proceeding from three openings at the bottom of the cauldron. The steam column has been seen to rise to 20,000 feet; but luckily the volcano was quiescent, and the lava does not seem to have overflowed recently.

Early in November Shackleton and three companions started their journey towards the pole. On the 26th they had passed Scott's 'farthest south' (82° 17′), and found that the great mountain scarp now trended E. across their path. Shackleton, therefore, ascended the Beardmore glacier—a colossal river of ice 120 miles long and often 40 miles wide—which led him up from the low Barrier ice to the plateau at 7000 feet. For nearly 200 miles they journeyed on the ice-plateau, rising gradually to 10,050 feet. On 9 January 1909, when they had reached 88° 23′ (less than 100 geographical miles from the pole), they were compelled to turn back. On their return Wild discovered coal and fossil corals on the upper Beardmore. They reached safety after experiencing extraordinary difficulties throughout a journey unsurpassed in polar annals.

Meanwhile a small party under another Australian, Armytage, had added to the geological knowledge of the western mountains. But an event ranking with Shackleton's 'farthest south' was the location of the magnetic pole by David and Mawson. Early in October 1908 this party started their hazardous journey up the coast. Only one who had experienced the peculiar dangers of sledging along an Antarctic coast with impassable glacier-walls on one side, open water on the other, and cracking sea-ice beneath him, can realize what they accomplished on this magnificent journey. For two months the small party man-hauled their sledges northwards over sea-ice until they reached the Drygalski Tongue. The peculiar feature of this coast is that the outlet glaciers, draining from the ice-plateau through the marginal ranges, send out huge floating tongues of ice into the sea. Thus the Drygalski is like a huge wharf, projecting nearly 40 miles from land. Here the party turned inland and climbed the Larsen glacier to the plateau, which near this part of the coast is about 3000 feet high. They marched on NW. towards the south magnetic pole, gradually rising until the plateau was 7350 feet above sea-level. Each day the magnetic needle dipped more and more, until on 15 January it dipped 89° 45′. Exact readings were very difficult, but Mawson calculated that 13 miles more would place them practically at the magnetic pole; accordingly next day they marched on, and Professor David took possession of the area for the British Empire. On their return, by one of the curious coincidences of exploration, they reached the coast at Relief Inlet on the same day as the *Nimrod;* for the ship had no knowledge where they would turn inland, and was cruising along looking for depots. One has only to recall what happened at the same place to Scott's northern party in 1912, to realize how near to death was this worn-out magnetic pole party in February 1909.

On 30 July 1923 a large area of the Antarctic regions, including much of the territory explored by Shackleton in 1908-9, was constituted a British dependency under the jurisdiction of the governor-general of New Zealand. The new dependency stretches from the ocean to the south pole between the meridians of 160° E. and 150° W., but does not take in the lands round the magnetic pole annexed by Professor David; this lies within an area named Adelie Land in 1840 by Dumont D'Urville (who sighted its coast, but did not land on it), and the area is nowadays claimed as French territory. On 13 December 1924 Adelie Land—defined as extending from St. Anne's Point to Rabbit Bay—was, along with the Kerguelen and Crozet archipelagoes and other French islands in the Southern Ocean, created a national park of refuge for marine mammals and penguins.

In 1910 and 1911 four expeditions entered the Circle. Of these Filchner's penetrated the Weddell Sea, in the American quadrant, and found an ice-barrier at its head resembling the Ross Barrier. A Japanese expedition landed at King Edward VII Land. Amundsen took up his quarters on the Ross Barrier at the Bay of Whales, and made a successful dash with dog-sledges to the pole. He found the plateau scarp continuing south of the Beardmore Glacier, marked by high mountains here as it is farther north. He reached the pole on 14 December 1911, just a month before Scott and his British party.

Scott's expedition, which because of his tragic

death is still the most memorable of Antarctic expeditions, was also probably the most completely organized of any; for the scientific results to be obtained were considered quite as important as the conquest of the pole, and the attainment of them was mainly left to specialists. Three members of the geology school of the university of Sydney accompanied the expedition. Priestley was Professor David's colleague on the previous expedition, and had been doing research work at Sydney. Debenham had just graduated there. Griffith Taylor, a Commonwealth official, was instructed to study especially the aspects of Antarctic geology and meteorology which bore on Australian problems. The expedition left Lyttelton in New Zealand in November 1910, and by the end of January had built their hut at Cape Evans, between the 1902 and 1907 huts. The northern party (under Lieutenant Campbell) was landed at Cape Adare, and during the first summer explored the glaciers to the north. A very complete study of the penguins and of the ice conditions was made by Levick and Priestley; Scott, meanwhile, was busy laying his depots to

MacMurdo Sound.

the south. On their return from this work three men and four ponies went adrift on the sea-ice. Luckily the wind drove the floes ashore, but three ponies were lost, in addition to others killed on the barrier.

In January 1911 the western party—consisting of Taylor and Debenham (geologists), Wright (physicist) and seaman Evans—sledged up the Ferrar glacier to its junction with the Taylor glacier. They surveyed the latter, found that it terminated 25 miles from the sea, left their sledge in an alcove in the glacier, and portaged to the sea, traversing a lake five miles long, full of algae. The ice-free valley was found to resemble closely those of the Swiss Alps, and the great rock-barrier across it (2400 feet high) is

unique in Antarctica. Returning to MacMurdo Sound, they traversed the Piedmont, sledged up the centre of the greatly dissected Koettlitz glacier, and surveyed the bare valleys below Mount Lister. These resemble in structure the clusters of cirque valleys of the Rockies, but are much larger. A subglacial stream, frequented by seals, ran for 25 miles from Heald Island to the sea. The party sledged back round the breaking barrier, and reached Hut Point on 15 March.

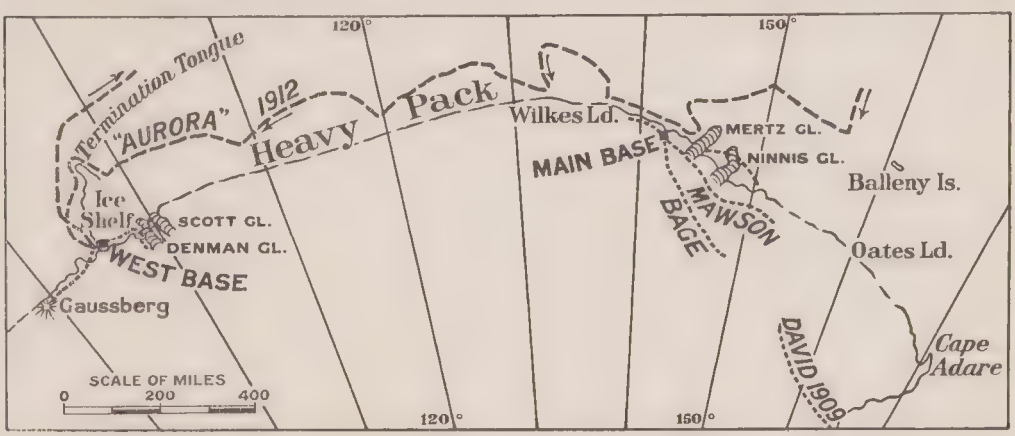
A gallant journey by Dr. Wilson, made during the depths of winter to study the emperor penguins at Cape Crozier, stands unrivalled as a test of endurance. His party was away for five weeks, sledging by the light of a candle when the moon was not visible. A temperature of −77° F., or about 110° below freezing point, was experienced. A blizzard at Cape Crozier blew away most of their gear, but they brought back embryos that gave valuable details concerning the evolution of this most primitive of birds.

On 31 October 1911, in the second summer, Scott left Cape Evans on his last journey. Motor-sledges, dogs and ponies helped him on his earlier stages to the Beardmore glacier, but south of latitude 83° man-hauling carried out all the work. The last supporting party under Lieutenant Evans left them at 87½° with their plateau journey half completed. On 16 January 1912 the British flag flew at the south pole. They found Amundsen's record, and turned back for their return journey a distance of 800 miles. Seaman Evans's accident and illness delayed them fatally. Yet Wilson collected most important fossil ferns at the head of the Beardmore, and carried them on to their last camp. After Evans died, Oates fell ill, and it was a feeble party that raced famine in the awful March cold of the Barrier. A severe blizzard destroyed their last hopes, and the party perished 11 miles from One-ton Depot—about 100 miles from Ross Island.

The second western party (Taylor, Debenham, Gran and Forde) left headquarters on 7 November 1911 for Granite Harbour, travelled up the coast for three weeks, and on arrival at Discovery Bluff—where the ship was to pick them up—built a rough granite hut. For over two months seal-meat was their staple food. The large inlet was mapped by Debenham, who found interesting minerals, including topaz. Two genera of wingless insects, the first found in eastern Antarctica, were discovered in the moss at 'Botany Bay.' The expedition next portaged its sledge up 1000 feet of granite cliff, marched up the Mackay glacier, and climbed a prominent nunatak (Mount Suess, 4500 feet). Here well-preserved fossil fish of Devonian age were discovered, and also specimens of bituminous coal. On their return to the rendezvous the ship was unable to relieve them, the pack-ice being 20 miles wide; so, after waiting a month until the food-supply ran short, they made their way back over the untraversed Wilson Piedmont glacier, and were picked up on 15 February 1912 at the head of MacMurdo Sound.

The northern party (under Campbell) had been landed early in 1912 at Evans Cove. They explored the glaciers round Mount Melbourne for some weeks, and then found that the same belt of pack-ice prevented their relief. Burrowing into a snowdrift at 'Hell's Gate,' they managed to survive the long winter night under conditions of starvation never experienced before in the Antarctic. In the spring, with two men out of the six sick, they managed to sledge over the frozen sea back to headquarters. In the last summer Priestley led a party up Erebus, and Debenham prepared a detailed survey of this most interesting volcano, while by means of sounding balloons Dr. Simpson investigated the upper air of Antarctica for the first time. Simpson and Wright carried out accurate magnetic and pendulum research on a scale not attempted on any other expedition. On one of his voyages Captain Pennell, in the *Terra Nova*, discovered Oates Land, W. of Cape Adare.

In December 1911 the Australasian Antarctic expedition left Hobart for the Antarctic, under the leadership of Dr. Mawson. This expedition was almost entirely financed by public and private subscriptions in Australia. Twenty-six men, mostly young Australian graduates, were landed at Commonwealth Bay on the Antarctic continent, while five others maintained a wireless sta-



Aurora's Bases.

tion and carried on valuable research in Macquarie Island, which lies almost half-way (900 miles) between Tasmania and Antarctica. Macquarie Island was left on Christmas Day, and the *Aurora* sailed due S., reaching heavy pack-ice off the Balleny Isles. A course was made to the west, where the ship entered the open D'Urville Sea, and a rock-girt coast was reached on ?

January 1912. Here the party landed, being the first to set foot on the Antarctic continent between Cape Adare and Gaussberg, a distance of 1800 miles. The rocky area was found to be one mile in length and half a mile in extreme width. Behind it rose the unbroken inland ice; and no similar 'oasis,' as Mawson appropriately terms it, was encountered on the whole north coast. On the 19th the *Aurora* sailed with Wild and his party to make a landing farther W. On the 24th Captain Davis sighted high land, to which Wilkes's name was given in memory of the bold American explorer of 1840. Heavy pack-ice prevented them from reaching land where it had been reported by earlier exploring ships, but Totten Land was approached within seven miles, and seems to have been wrongly described. On 8 February Davis reached 'Termination Land,' to find it a huge ice-tongue projecting from shelf-ice, 200 miles north of the continent. On the 15th the party was landed on floating ice at the western base, near what was later called Queen Mary Land, 1200 miles from Mawson's headquarters at Commonwealth Bay. The *Aurora* then returned to Hobart.

It was soon evident that the main (Commonwealth Bay) base was swept by the strongest winds ever recorded. The average wind-force for the first year proved to be 50 miles per hour (compare this with the European average of 10·3 miles, and the United States average of 9.5 miles). On 16 August the average for one hour was 105 miles. It was necessary to wear spikes or crampons on the boots in order to traverse the region at all. During the winter the infrequent lulls were employed in erecting a wireless mast, which was done by 30 September. Messages were sent out, and received at Macquarie Island, but nothing was heard in Antarctica. In October a terrific gust tore down the apparatus. On 9 November Mawson, with Ninnis and Mertz, started to explore the continent to the east. Two days were spent among the crevasses of the Mertz glacier, 50 miles E. of headquarters. Another 50 miles brought them to the Ninnis glacier, which, like the Mertz, drained to the sea down a shallow valley about 20 miles wide. Here some thrilling escapes from crevasses were recorded. On 13 December they were sledging 280 miles E. of headquarters along the Piedmont slopes and some 20 miles from the sea, where the ice is usually free from crevasses; when they do occur, crevasses in the Piedmont are especially dangerous, since one's track generally lies along their course and not across them. Mertz and Mawson crossed several safely, but on looking back found that Ninnis had disappeared. With his sledge and team he had fallen into a fathomless crevasse. Only ten days' food for the men, and nothing for the dogs, remained for the survivors. They decided to make their way back parallel to their outward track, but farther south, where the ice might be less disturbed. One by one the dogs were killed and eaten. Early in the New Year it became evident that Mertz was weakening much more than Mawson. Using a sail on the sledge, they managed to make some mileage, but on 7 January 1913 Mertz became delirious and died in the night. Mawson was still 100 miles from safety, with the crevasses of Mertz glacier ahead of him. On the 17th he fell the full length of his harness into a crevasse, and was only saved because the sledge was caught on the snow-bridge. Two desperate efforts ended in his reaching the surface. Thereafter he carried a rough rope ladder, which enabled him to climb out without such exhausting labours. On the 29th, with only two pounds of food, he came on a small depot left that morning; then he reached a cave cut out of the ice, only five miles from the hut, and there was held up by a blizzard for a week. His terrible journey ended on 8 February.

On 10 November 1912 the magnetic pole party (Bage, Webb and Hurley) started their journey to the south. After rising to 3650 feet, they descended 1500 feet into the broad valley that feeds the Mertz glacier; crossing it, they marched over the unvarying ice of the plateau, Webb recording the magnetic dip each day, and on 21 December reached their farthest south, 175 miles NW. of David's 1908 terminus. Here the dip was 89° 43.5', only 16½ minutes from vertical. The plateau was 5900 feet above sea-level, or about 1300 feet lower than David's station. They estimated that the maximum dip would occur about 60 miles south—which would fix that elusive locality, the south magnetic pole. They reached the hut on 11 January 1913, after a fine journey of 600 miles, which filled a large gap in our knowledge of the ice-plateau on this side of the pole.

On 8 November 1912 the east coast party (Madigan, McLean and Corell) followed a route parallel to Mawson's, but largely over sea-ice. Several rock islands (nunatakker) were investigated, and showed that the continent was here built chiefly of gneiss. They crossed the Mertz glacier where it was afloat and over 20 miles wide, then descended to the sea-ice and sledged across some 40 miles to the Ninnis ice-tongue; this crossed, open sea appeared to the east. Nevertheless they sledged another 80 miles eastwards—a fine performance, in view of the precarious nature of the sea-ice. In 18 December they turned to the coast, and discovered very interesting formations at Horn Bluff. Here a vast dolerite sill seems to have penetrated Beacon sandstones, just as first recorded far to the south by Ferrar in 1903. On their return journey they found great granite cliffs forming the coast-line between the Ninnis and Mertz glaciers. Shorter journeys were undertaken by other parties. Bickerton marched 130 miles W. along D'Urville's coast, one interesting discovery being that of a meteorite on the snow. Stillwell carried out detailed geological surveys within 50 miles of the hut, discovering incidentally a wealth of bird-life on the small islets of the coast. Other members of the main party were Close, Hannam, Hodgeman, Hunter, Murphy and Whetter.

The western base party (under Wild) had built their hut on the Shackleton ice-shelf, 12 miles north of the continental ice—and, curiously enough, just as far north of the Antarctic Circle. This party comprised Wild, Jones, Dovers, Harrison, Hoadley, Kennedy, Moyes, and Watson. In August 1912 they sledged E. over the ice-shelf, and laid a depot some 20 miles away among nunatakker of gneissic granite. Here also the winds were of phenomenal force, men being lifted off the ground and flung 20 feet by the gusts. Another depot party under Jones was held up by a blizzard for 17 days, without being able to strike tents. In November Wild led a party to the east, but was blocked by tremendous crevasses where the Denman glaciers entered the ice-shelf—the boundary chasm was 1000 feet wide and 400 feet deep. Jones led a party to the west for 200 miles, and at Haswell Island discovered one of the two known rookeries of emperor penguins. On 22 December the Gaussberg was reached, and cairns made by the German expedition were found. The whole party was re-

lieved by the *Aurora* on 22 February 1913. The large stretch of explored coast was given the name of Queen Mary Land. It had not been possible to pick up Mawson on his return to his base, and so a party of six remained to search for him; they carried out further scientific work, and were finally relieved by the *Aurora* on 12 December 1913.

The Macquarie Island party was in charge of Ainsworth of the Commonwealth weather service; he carried out valuable meteorological work, which was sent regularly by wireless to Australia and incorporated in the daily weather-maps. Much light was thrown on the Antarctic low-pressure systems, which largely control the rainfall of southern Australia. Macquarie Island is especially rich in seals, penguins and other forms of southern life, which were studied by Hamilton, while Blake made a detailed survey of the island and investigated the geological features. In September 1912 they received faint signals from Mawson's base, but not until 3 February 1913 were they able to send a message to Antarctica. The island party agreed to stay and maintain communication until Mawson could be relieved in the following year. Captain Davis in the *Aurora* carried out numerous soundings south of Tasmania—a very interesting discovery being 'Mill Rise' (in lat. 47° S.) where the ocean floor rises sharply from 2500 fathoms to 543 fathoms. Macquarie Island itself is really a submerged peak rising 16,000 feet from ocean depths, though its highest point is only 1420 feet above sea-level.

Yet another Antarctic expedition has special interest to Australians, for it contained three Australians (Gaze, Jack, and Richards) as well as J. F. Hurley, who had accompanied Mawson in 1911, and was to be the official photographer of the A.I.F. during the war. Sir Ernest Shackleton in the *Endeavour* late in 1914 proposed to make simultaneous attacks on the Antarctic from the Weddell Sea and from the opposite (Ross Sea) region. He hoped to land a party S. of South America and march over the plateau to the Ross Sea base; but 30 miles from land he was beaten back without landing, and his ship was sunk, though after a perilous drift on pack-ice his party was ultimately rescued. The photographic material obtained by Hurley was especially noteworthy. The other party under Macintosh was safely landed at Scott's old headquarters in January 1915; the ship was carried north, enclosed in a field of ice, but ultimately broke clear and safely reached New Zealand. The shore party (including the three Australians) was fully employed in laying depots to the Beardmore glacier. In January 1916 they laid their last depot at 84° S., but their return journey was as perilous as any in Antarctica. Spencer Smith succumbed to scurvy, and Macintosh and Hayward were temporarily left behind while the stronger members pushed on for food and help. Ultimately the invalids were brought to Hut Point, and soon recovered. On 8 May Macintosh and Hayward tried to reach Cape Evans across the sea-ice, but were lost (probably through the breaking of the sea-ice) in a blizzard which sprang up soon after. A Commonwealth relief expedition under Captain Davis rescued the survivors in January 1917.

See for the earlier voyages Mill's *Siege of the South Pole;* for those after 1900, Scott's *Voyage of Discovery,* Shackleton's *Heart of the Antarctic,* Scott's *Last Expedition,* Mawson's *Home of the Blizzard,* Taylor's *With Scott, The Silver Lining,* and Davis's *With the Aurora in the Antarctic.* Gr.T.

Anteater, Banded. See BANDED ANTEATER.

Anthocerotales. See LIVERWORTS.

Antidesma, a genus of the family Euphorbiaceae, widespread over tropical and subtropical regions. The four species indigenous to Australia range from Queensland into the Northern Territory. *A. Dallachyanum* (Herbert River Cherry) is a shrub or small tree, whose fruit (the size of a large cherry) has a sharp acid flavour resembling that of the red currant, and makes an excellent jelly.

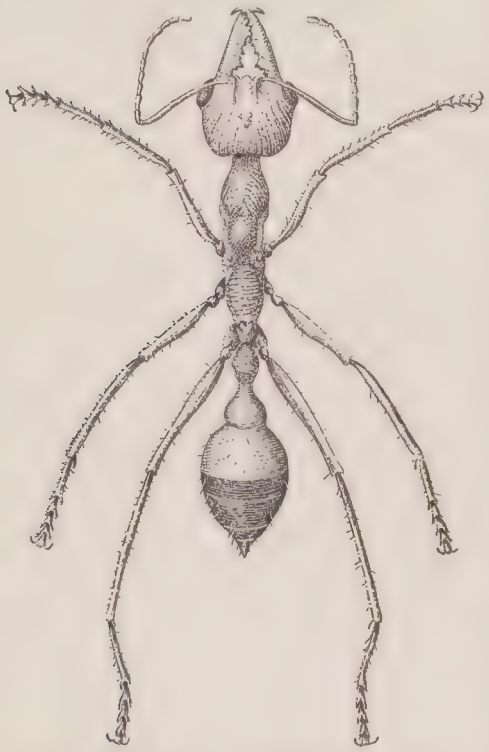
Antimony. Most Australian antimony ores contain a payable quantity of gold. Costerfield in Victoria is the largest producer in Australia, and supplies 4 per cent of the world's antimony. The other chief producers—in the past—were Hillgrove, Kempsey, and the Nambucca district, all in New South Wales, each of which had their own smelters. At the present time the only works treating antimony ore are situated in a suburb of Sydney. Here the ore, which should not contain less than 50 per cent of sulphide of antimony, is smelted direct in a reverberatory furnace with soda-ash and oxide of iron to slag off the silica, while scrap iron is added to combine with the sulphur to form an iron matte. The crude-antimony produced, which contains about 95 per cent of metal, is refined in another reverberatory furnace where the percentage is brought up to 99.5 per cent. The chief impurities in the 'star' antimony are a little tin from the scrap iron, and lead from the original ore. Antimony not infrequently occurs associated with galena (lead sulphide) in small quantities. At the Port Pirie smelters, where Broken Hill ores are treated, the antimony is concentrated as hard lead, and used in the manufacture of various lead-antimony alloys. F.D.P.

Anti-transportation League. See TRANSPORTATION.

Ant-lions, vernacular name of the insect family Myrmeleontidae, belonging to the order Planipennia (q.v.). Strictly speaking, the name 'ant-lion' applies only to the larvae of this family, which are in general short, oval, insectivorous grubs with prominent mandibles, commonly found in sandy soil or on sea-beaches, where they form conical pits. At the apex of each pit lies a single larva on the watch. Should an ant fall into the pit—or be placed in it—the larva's mandibles quickly seize it; if it struggles to climb the shifting pit-sides, the larva often flicks up sand to pelt it and bring it down within reach. The adults somewhat resemble dragonflies, with which they were formerly classified in the obsolete order Neuroptera. Their powers of flight are comparatively feeble. Australia has a large number of species, especially in the dry central districts. The genus *Glenoleon* has many species marked with black spots or bands; those of *Periclystus* (plate xix, fig. 27) are strikingly beautiful. Other common genera are *Protoplectron, Myrmeleon* and *Acanthaclisis.* See PLANIPENNIA. R.J.T.

Ants, insects of the family Formicidae, belonging to the order Hymenoptera. This family may be almost said to have its headquarters in Australia, and is undoubtedly the dominant group of insects here; its members are found everywhere from the coast to the driest parts of the central desert, and are often little short of a curse. Many species astonish visitors from other coun-

tries by their abnormal size. The most striking forms belong to the genus *Myrmecia* (Bulldog Ants, also known as 'soldier ants' and 'inchers'), the oldest known type within the family and certainly the fiercest, capable of inflicting a very painful bite and therefore dreaded.



Red Bulldog Ant (*Myrmecia gulosa*).

They are abundant and aggressive in most parts of Australia; their average length is an inch, but specimens an inch and a half long are known. Their jaws are not very stout; but they are long, and on one side irregularly serrated, so that they have a powerful grip. Bushmen occasionally make an ant fasten its jaws through the sides of a wound, and then cut off the head, which holds the gash together with its clenched jaws for as long a time as is desired. It is, however, the sting that is most painful, being often worse than the sting of a bee. They usually build a slightly elevated cone or crater in loose soil, where possible beneath a log or stone; the galleries sometimes extend several yards, and the nest may go to a depth of two feet, although usually it is less. The actual entrance to a nest is about an inch in width. Their prey consists largely of other insects, although frogs, lizards and other small creatures are killed and eaten. The larvae average almost an inch in length. They are rather narrow, and the head-end curls round; when fully-fed, they spin a pale silken cocoon.

The commonest and most aggressive species about Sydney is *M. forficata*, a reddish ant, with the tail-end blackish; it attacks on the slightest provocation, or no provocation at all, and in certain parts of the National Park almost every passer-by is certain to be stung by it. In Tasmania *M. pyriformis* is the commonest species. It has a general resemblance to *M. forficata*, but usually works only at night, when it makes several openings to the nest, and closes them again on the appearance of daylight. The Blue-black Bulldog Ant (Blue-incher), *M. tarsata*, is also common in coastal districts of eastern Australia. It is less aggressive than most species of the genus, and on being disturbed often retreats into its nest; but its sting is quite as severe as that of the others.

Jumper-ants—of which there are several kinds, all of the genus *Myrmecia*—are generally somewhat smaller and less shining than the others, and are usually black and yellow. They are rather more active and vindictive. When moving about on their ordinary business they have a very quick walk, but when attacking they proceed by a series of quick jumps, from three inches almost to a foot in length, and as their nests may have several entrances caution is needed in their vicinity. Other large but harmless ants (none of which can sting, though many can bite) belong to the genus *Camponotus; C. intrepidus* is a huge black species as big as a bulldog ant, whose nests are conspicuous in the bush. *C. nigriceps*, the large Sugar-ant, is a pest in houses. Another stingless genus is *Polyrhachis*, containing some beautifully coloured ants, of which *P. ammon* may be taken as representative. Amongst the objectionable species the Mound Ant (*Iridomyrmex detectus*) is prominent; its huge nests are particularly destructive to garden paths. This ant gives off a strong odour, and bites viciously. The somewhat smaller Green-head (*Ectatomma metallicum*) also has a reputation for biting and can also sting. One of our most interesting genera is *Leptomyrmex*, of which *L. erythrocephalus* (from the Blue Mountains) is a well-known species. These ants carry the abdomen curled up over the thorax; no queen has ever yet been discovered in any of their nests.

In the coastal regions of tropical Australia the most aggressive of all ants is the Green Tree-ant (*Oecophylla virescens*), which swarms over and savagely bites anyone who ventures to disturb its home in the foliage. Occasionally it makes its nests in orange trees, and pickers suffer severely from it; fortunately it does not sting. Dodd in 1902 thus described the nest-building of *O. virescens* in Queensland. 'It is decidedly interesting to observe the insects engaged upon the construction of their domiciles. If the foliage is large or stiff, scores or even hundreds of the ants may be required to haul a leaf down and detain it in place until secured, both operations taking considerable time. It is quite a tug-of-war matter to bring the leaf into position and keep it there. The insects holding it have a chain of two or three of their comrades fastened on to them, one behind the other, each holding its neighbour by its slender waist, and all at full stretch and pulling most earnestly . . . . When the leaf is far apart the ants form themselves into chains to bridge the distance and bring it down; many of these chains are frequently required for a single leaf . . . . several of these chains were from three to four inches long . . . . Up or along these living bridges other ants were passing. Now for the web material used to build the nests. It is furnished in fine and delicate threads by the larvae: moreover, I have only seen what appears to be half-grown examples used for the work—I have never seen a large larva being made use of. The soft and tiny grubs are held by the larger ants, who slowly move up against those pulling. Each grub is held by the middle, with head pointing forward, its snout is gently made to touch the

edges of the leaves where they are joined, it is slowly moved backwards and forwards and is undoubtedly issuing a thread during the operation, which adheres to the leaf edges, and eventually grows into the web. When this web is completed it must be composed of several layers to be strong enough for the purpose of securing the leaves.' (*Victorian Naturalist* 18, 136-140).

Besides her natural plethora of ant-life Australia has acquired certain introduced species as pests. The most troublesome is the minute reddish Pharaoh's Ant (*Monomorium pharaonis*), common in many parts of New South Wales and Queensland, and often seen on ships. No food is safe from its attacks, unless isolated by the housewife's remedy, the saucer of water with a film of oil. Another introduced species is *Pheidole megacephala*, also a minute red species, the soldiers of which have larger heads. These swarm especially in the warmer coastal districts; although always ready to carry off household food, their favourite diet consists of other insects, so that they cannot be wholly regarded as enemies. See HYMENOPTERA. For White Ants, see TERMITES.

R.J.T.

Aphaniptera. See FLEAS.

Aphides, insects of the family Aphidae, belonging to the sub-order Homoptera of the order Hemiptera. The native Australian species are few, and none are troublesome; one curious species affects the cypress pines of the mainland and the Oyster Bay pine of Tasmania. The pest-forms are all introduced species. The worst is *Phylloxera vastatrix*, the dreaded grape-vine scourge; so far this has appeared only in Victoria and New South Wales, where every vine attacked has, as soon as the presence of the pest was discovered, been destroyed. Stringent regulations are in force to prevent its introduction to the other States. In Australia, curiously enough, only the root-form is known; the leaf-galls have never been seen.

The Orange-aphis (*Siphonophora citrifoli*) is common on the orange, and the curious fumagene fungus that lives on its 'honey-dew' causes the leaves to appear coated with soot.

In some years the Wheat-aphis (*S. granaria*) damages crops by sucking the stems of wheat, so that they break down. *S. rosae* is almost universal on garden roses, and may be seen flying in great numbers in spring. This species, besides laying eggs in autumn, is also viviparous; a young rose-aphis may often be seen with beak thrust into a leaf before it has completely left the parent's body.

The Woolly Aphis (*Schizoneura lanigera*) infests apple trees—except those grown on 'blight-proof' stocks—and causes numerous galls on the roots, trunk and branches; it is occasionally seen amongst the pips of the apples themselves. An enemy of this pest has been discovered in the tiny chalcid *Aphelinus mali*. Supplies of this valuable parasite were sent in 1921 by Dr. Howard, chief of the bureau of entomology at Washington, U.S.A., to R. J. Tillyard (q.v.) at the Cawthron Institute in New Zealand; Tillyard successfully established, propagated and distributed the wasp (100,000 living individuals were sent out to orchardists during the summer of 1924-5), and woolly aphis is now well under control in all parts of New Zealand. From 1923 onwards consignments have been supplied to all the Australian States, and in Queensland and Western Australia, where distribution has been most general, good results have followed. The wasp-females lay their eggs separately in the bodies of living aphids, and the grub attains full growth by devouring its host, and pupates within the skin of the dead aphis. Four or more broods of the parasite appear in the course of a single summer. All cruciferous plants in Australia are liable to the attacks of the Cabbage-aphis (*Aphis brassicae*), which in dry seasons will destroy whole crops of cabbages or swedes. The Green Peach-aphis (*A. persicae*) and its black congener (*A. persicae niger*) greatly infest peach-trees and may considerably diminish the crop. The latter also occurs on chrysanthemums and other garden plants. Some writers classify these two species as belonging to the genus *Myzus*. See HEMIPTERA.

R.J.T.

Apium, a genus of the family Umbelliferae, containing a few widely distributed species. The calyx-teeth are inconspicuous; petals broad, with a shortly inflexed apex; fruits almost turgid, with 5 prominent ribs. The plants are herbs with dissected leaves. *A. australe* (Australian Celery) is a perennial herb which has been used as a culinary vegetable. There are two forms of this species, one found on the sea-coast with thick, obtuse, succulent leaves, and an inland form with narrow, prickly-pointed foliage. *A. leptophyllum* (Wild Parsley) a slender annual with thread-like leaves and branches, is occasionally eaten by stock. Like other members of the genus it tends to become acrid when grown in a damp place. It should be capable of improvement by cultivation. The exotic species *A. graveolens* is the common Celery and *A. petroselinum* the Parsley of the kitchen garden.

Apocynaceae, a large tropical or subtropical family of trees, shrubs or twining plants —rarely perennial herbs—with opposite (or whorled) entire leaves, usually inconspicuous flowers, and drupes or berried fruits. *Alyxia* is a small genus ranging over Malaysia and southern Asia. With one exception the seven endemic species are confined to eastern Australia. *A. buxifolia* is a low, rigid, seaside shrub ranging from Western Australia to New South Wales. Its vernacular name, Tonga bean wood, is a misnomer; it should be tonka bean wood, as it is due to the strong smell, resembling that of coumarin (a tonka bean product), emitted by the timber. *Wrightia saligna*, a small tree found in Queensland and northern Australia, has a timber resembling that of the English cedar. See ALSTONIA, CARISSA, CERBERA.

Apostle-birds. See GREY JUMPER and CHOUGH, WHITE-WINGED.

Apple, a name popularly applied to several indigenous trees outside the Rosaceae. The broad-leaved, dwarf, narrow-leaved and smooth-barked apples are species of *Angophora* (q.v.). The black apple is a *Sideroxylon*, the crab apple a *Schizomeria*, the emu apple an *Owenia* or a *Petalostigma*, the kangaroo apple a *Solanum*, and the white apple an *Endiandra*.

Apples and Pears. These and other old-world fruits are grown most satisfactorily in the cooler southern districts of Australia or the elevated uplands of more northern areas; but Tasmania and Victoria together grow considerably more than half the whole Australian crop. In Tasmania especially apple-growing has become a most important industry since the improvement in refrigerating machinery in sea-

going vessels has allowed this fruit to be transported overseas without injury. In 1884 100 cases were exported from Hobart, in 1887 4000, in 1914 nearly a million. In 1922-23 about three million cases left Tasmania, half for the mainland, half for oversea countries. Though the acreage under apples in Tasmania is about 30 per cent below that of Victoria, the Tasmanian crop is almost 50 per cent bigger and 45 per cent more valuable.

Although many varieties are cultivated in the Commonwealth, exportable kinds are limited to the few that can stand a long voyage. At present the varieties most in favour for this purpose are:—Cleopatra, Jonathan, London Pippin, Rokewood, Rome Beauty, Stone Pippin, Yates, Granny Smith (New South Wales only), Dunn's Favourite, Rymer, Statesman (Victoria only), Nickajack (Western Australia only), Strawberry Pippin (South Australia only), Crofton, Scarlet Nonpareil, and French Crab (Tasmania only). Apple cultivation is expanding in Victoria, South Australia, and Western Australia; the product is in the main exported to England, though Western Australia still has a market for its fruit on the goldfields. In New South Wales and Queensland the increase does not yet satisfy local requirements. Several good local varieties have been raised, notably Granny Smith, Carrington and Trivett's Seedling. In New South Wales the most suitable districts for apple-growing are found on the tableland and its eastern and western slopes—near Goulburn, Bathurst, Glen Innes, Yass, Tumut and Batlow. In Victoria the suitable area is extensive, the chief districts lying round Portland, Western Port, and Mount Macedon, and in Gippsland. In Tasmania of late years the Huon River district and the north coast show a great increase of cultivated area; in South Australia orchards have spread along the Mount Lofty Range; and recently Western Australia has proved that apples of great excellence can be produced there. As that State is nearer Europe than the others, it will probably develop an extensive export trade. The Katanning and Mount Barker districts are specially notable for their orchards. In 1922-3 (the latest season for which figures are available) the Commonwealth produced 7,199,349 bushels of apples, valued at £1,995,269.

Pears of numerous varieties are grown extensively, but so far only for local consumption; although the fruit has been carried overseas with success, it cannot be depended on to stand a long voyage. Should means be perfected whereby soft fruits can be conveyed to distant countries, a large trade may develop. In 1922-3 the Commonwealth produced 1,315,274 bushels of pears, valued at £356,527. Victoria provided more than half the yield. W.S.C.

Arachnida, a class of animals having four pairs of walking legs, as distinguished from insects, which have three pairs only; this distinction was first made in 1815 by Lamarck. They have also two pairs of anterior limbs—the chelicerae and the pedipalpi—and the head and thorax combine to make a single segment, the cephalo-thorax. The class is divided into eight orders, of which five are represented in Australia—the scorpions (Scorpionida), spiders (Araneida), pseudoscorpions (Pseudo-scorpionida), harvest-men (Opiliones or Phalangida), and mites and ticks (Acarina). All these are discussed in separate articles. W.J.R.

Black Pencil Cedar.

Araliaceae, a family of trees, shrubs or woody climbers (rarely herbs), mostly tropical. The flowers are small, white, greenish or purple in umbels or panicles; fruit usually succulent; leaves simple or compound, often very large and handsome. Members of the endemic genus *Astrotricha* are heavily clothed with a woolly vestiture of star-like hairs. *Panax elegans* (Black Pencil Cedar) is an ornamental tree with large divided leaves, and a soft, light wood that is suitable for lining boards. *P. sambucifolius* (Elderberry Ash) has a sound, tough, prettily-streaked timber.

Araneida. See SPIDERS.

Arbitration. See INDUSTRIAL LAW.

Archer, THOMAS (1823-1905), born at Glasgow in Scotland on 27 February 1823, came to Sydney in December 1837 to engage in pastoral pursuits. In August 1841 he with his brothers John and David took about 5000 sheep from the Castlereagh River across the Darling Downs to the Moreton Bay district, and settled on Stanley Creek, near the Glasshouse Mountains. Hearing of the discovery of Fitzroy Downs by Sir T. Mitchell, Thomas Archer in 1848 found a track to the district from Jimbour on the Darling Downs, along or near which the railway now runs from Dalby to Roma; finding, however, that the distances were too great to attract owners of small flocks, he opened up a track north from the

Brisbane to the Burnett River, took up two runs there, and made a road through to Maryborough for the despatch of his wool to Sydney. In 1849 Archer went to California, and his younger brothers Charles and William took up the task of opening new country. In 1853 they discovered and named the Fitzroy River, and another brother (Colin) sailed a locally-built vessel from Maryborough into the mouth of the Fitzroy, and landed supplies just below a point where a rocky bar obstructs navigation; next year Charles Archer procured the reservation of this site for a township, to be called Rockhampton. Thomas Archer between 1853 and 1878 devoted himself mainly to the development of his properties in Queensland; in the latter year he settled in England, and in 1881 was appointed agent-general for his colony. This post he held in 1881-4 and 1888-90. He died in England on 9 December 1905. (C.M.G., 1884).—The dramatic critic and well-known writer, William Archer, was his son.

Archibald, Jules Francois (1856-1919), born at Warrnambool in Victoria, and trained on the local newspaper, after varied experiences in Melbourne and Queensland (including a brief but sensational career as correspondence clerk in the Victorian education department) became in 1879 a reporter on the staff of the Sydney *Evening News*. Here he met John Haynes, and co-operated with him in founding the Sydney *Bulletin*. For the next twenty years Archibald's life was bound up with that journal; while not specially responsible for its politics, he took complete charge of its literary side, and gathered round him the most brilliant coterie of young writers Australia had as yet seen. Several of them, indeed (e.g. Louis Becke), he may be said to have made; there was not one whom he did not train, and improve in the training. Henry Lawson, Victor Daley, A. B. Paterson, Barcroft Boake, Louis Becke, Steele Rudd, Price Warung, John Farrell—the list could be doubled with ease; and two more names must be added to his list of discoveries, though literature was not exactly their *métier*—those of James Edmond, who succeeded him as editor, and of Norman Lindsay.

After many vicissitudes—including the temporary editorship of W. H. Traill, who brought in Livingston Hopkins and Phil May—the *Bulletin* settled down with Archibald as editor, Edmond as his assistant, and W. Macleod as managing director, to a career unique in Australia (and possibly in the world) which has been thus characterized:—

> At the back of its owners' minds lay the keen desire to stimulate among Australians a love of their own country for its own sake; and from the first they printed, and paid for, every contribution in prose or verse which seemed to be inspirited by such a love, except where the style was too impossibly crude. The result has been the accumulation of a mass of written matter, not often 'literary' in any strict sense of the word, but instinct with the Australian spirit in most of its guises, and including here and there literature more genuine and of higher quality than any previous epoch of Australian letters can show.

This policy—to him it was more than a policy, it was a creed—was Archibald's special gift to Australia as an editor. As a sub-editor (and he was probably the greatest sub-editor Australia has known) he made the policy not only possible but successful by pruning away with delicate and almost unerring judgment the crudities and excrescences that abound in the writings of ardent but untrained youth, and so often stifle a budding genius by making it ridiculous.

In 1902 Archibald's health began to fail, and he withdrew gradually from active work. In 1914 he sold his interests in the *Bulletin* to the still working partners. In 1918, however, tempted by a good offer and the longing to give his critical powers free play again, he joined the staff of *Smith's Weekly*: but his physical strength was unequal to his mental powers, and he died (after a serious operation) on 10 September 1919. His will provided legacies for distressed journalists, hospitals and cancer research, an annual prize for a portrait by an Australian artist, and a sum of money for an open-air memorial 'commemorative of Australia and France having fought side by side for the liberties of the world.'

Archibald's father was an Irishman of Scottish extraction, and his mother a Frenchwoman of partly Jewish descent, so that the qualities of many races blended in him.

Architecture. The earliest buildings of this continent were hastily erected structures of wood roofed with sheets of bark, for timber was plentiful wherever men found it desirable to settle, and wooden buildings were easily and quickly built. Even to this day, in the remoter parts of the continent, the slab hut is the first attempt of the settler to provide shelter. The heat of the climate made shade a necessity, and the verandah soon became customary. Roofs of bark did not prove watertight; they gave place to shingles, which, with gutters around the eaves to catch the rainfall, and barrels or tanks to store it, provided a cleaner and more convenient water-supply than the creek or well. As population increased, saw-pits were provided and sawn timber made available, so that weatherboards superseded slabs, and floorboards took the place of tamped clay. Wooden dwellings show many attempts at design, mostly by way of unnecessary ornament, instead of good form and proportion. The wooden cottage will, for a long time to come, predominate in country districts, and its proper treatment is well worth while. When galvanized corrugated iron was introduced, its cheapness and ease of handling caused it to replace shingles for roofing, and in the hottest regions made it available for walls as well; in nearly all buildings for industrial purposes its use became universal. Much unnecessary ugliness is consequently prevalent.

The great danger of fire soon made more durable materials necessary in the growing towns. Where freestone was available, as in Sydney, it was quickly adopted for the more important dwellings, and Hobart followed suit. They were necessarily plain, and were designed, as was natural, on British examples, so much so that verandahs were not always provided; but, when they were, a simple and dignified pillared treatment was adopted, which, if it had been adhered to generally, would have given a distinctive note to Australian architecture. The constant arrival of new settlers from Britain, and more rapid intercommunication, kept Australia in such close touch with developments 'at home,' that every passing phase of architectural thought was repeated more or less closely—and it must be remembered that the 19th century was essentially one of revivals rather than of logical development. Hence during the first half of the century Italian designs were universal, mostly carried out in cement over brick; as our bricks

were poor in quality, this was an advantage. Government house at Adelaide is a typical example of domestic architecture without verandahs, and Sir Thomas Mitchell's house at Darlinghurst, Sydney, of the pillared shelter type. On one side of the latter there is a perfectly proportioned Greek Doric verandah built entirely of wood, and still in good preservation. Towards the middle of the 19th century, when taste was at a low ebb and cheap ornament popular, commercial firms made a specialty of building accessories such as verandah pillars, railings, and roof crestings, in cast iron of the poorest design, and the simple Italian style of domestic architecture degenerated into an over-ornamented type, of which many examples still exist.

Structures for commercial purposes were at first severely plain, but, as soon as the initial difficulties of settlement were overcome, some attempt at design became apparent. The Italian Renaissance style in its many forms was almost universally adopted, and is still favoured. Fortunately commercial architecture largely escaped the craze for cast-iron ornament which was so prejudicial to our domestic architecture. In some cases a tendency to over-richness in ornament is noticeable; but on the whole reticence, dignity, and good proportions distinguish the more permanent examples, which are mostly occupied by banking, insurance and commercial companies. Several excellent examples are to be seen in Collins-street, Melbourne.

Similar praise cannot be given to most of the buildings used for retail trade. In the early days, before the introduction of plate glass and the great display of goods it encouraged, shop-fronts were divided up into many small panes, and the supports to the superstructure were left visible, the whole effect being fairly harmonious and satisfying. At the present time the insistent demand for the greatest possible area of undivided glass at the street level, and for shelter of the displayed goods by street verandahs, renders a satisfactory solution almost impossible. Add to these the desire of every trader to call attention to his own business, and the universal use of advertising signs, and it will be seen why shop architecture is on the whole vulgar and self-assertive. There are of course exceptions, but not enough to affect the general impression.

The early public buildings of Australia were naturally very simple. Most have disappeared, but there still remain at Port Arthur, in Tasmania, prison, church, and administrative buildings constructed of roughly worked stone. The purpose of the buildings is well expressed and the effect satisfactory, but special architectural character is lacking. Buildings in Hobart, of a later date but worth studying, are the Tasmanian club (built for a bank in 1828), a simple Italian design with a pillared porch; and the custom house (now the parliament house) erected in 1832, and recalling English Renaissance architecture of the 18th century.

In Fowles's *Sydney in 1848* many of the buildings of early date are illustrated; they generally favour Italian or Classic design. The old post office in George-street, with its Doric portico, and the Wesleyan Centenary church in Greek Doric, are both demolished; but the Congregational church in Pitt-street, the supreme court, the houses of parliament, Fort-street school, and the Royal hotel in George-street, all still in existence are typical examples. The four last-named are noteworthy because verandahs and balconies are marked features in their design, thus showing appreciation of climatic conditions. In a different style are the old Scots church in York-street, with its pointed windows, and the government house (the work of Blore, an English architect) in Perpendicular Gothic.

Melbourne was founded in 1837, and its inhabitants were perforce satisfied with the simplest buildings until goldmining, after the first mad rush to the gold diggings, had settled down into a steady industry. Then they commenced building in earnest, and generally favoured simple but dignified designs of Italian character. The national model and training schools, and the old police station and town hall (shown in *Victoria Illustrated*, published in 1857) are good examples. The post office of 1857 was a shed-like building of one storey with verandahs of the common type. Prince's Bridge, when built in 1850, consisted of a single arch of masonry, satisfactory in design, but approached by sloping embankments of earth, very different in appearance from the fine bridge of to-day. Slightly later in date are the Melbourne club, a simple but dignified astylar Italian design of three storeys, and St. Vincent de Paul's orphanage at South Melbourne, an effective composition of central tower, two-storey wings, and connecting open arcades. Perth was settled before Melbourne, but like Adelaide and Brisbane, retains but few examples of public buildings of early date, and these follow the same lines as in the other States.

The years from 1860 onwards saw the development of the towns of Australia into modern cities. Most of the buildings now existing are of this period, which is characterized by great diversity in design and construction; varying from the dignified parliament house, which so finely terminates the vista of Bourke-street, Melbourne, to the essentially modern sky-scrapers which are becoming dominating features in all large cities. As good examples of the public buildings of the period may be mentioned the art gallery, the education department, and part of the treasury in Sydney; the parliament house, the town hall, and the new post office in Spencer-street, Melbourne; the supreme court in Adelaide; and the lands office in Brisbane.

Fortunately public buildings have not so far become too lofty, this defect being confined to commercial structures and residential flats. In Sydney the limit has been fixed at 150 feet in height, and even this is too great for the width of the streets prevailing in that city. Their architectural effect is not altogether satisfactory; however well designed the street fronts may be, the flanks and rear stand out in unrelieved bareness, too often disfigured by huge advertisements. In domestic architecture, on the other hand, the tendency in the suburbs is to reduce the number of stories, dwellings on one floor being preferred mainly because domestic servants cannot be found, and the mistress of the house finds a one-storey house easier to work. In design, also, an improvement commenced in the eighties of last century, and picturesque tile-roofed dwellings, now common throughout the principal cities and towns, began to make their appearance. They are adapted from the type current in Britain and the United States, but have more verandah and balcony space, which in the best examples forms an integral part of the design.

Ecclesiastical architecture in the early days of settlement was necessarily simple, and sometimes adopted Gothic features in a crude form, as in the church at Port Arthur. But St. George's, Hobart, with its fine tower, and St. James's, Sydney, are more characteristic of the early period, when some form of Classic or Renaissance

design was adopted. It was not long, however, before the Gothic revival in England was felt in Australia, and from that time (in the forties or fifties of last century) became almost universal, even spreading to educational buildings, like the universities, and the colleges connected with religious bodies, and to a few commercial structures and large residences. Australia possesses many fine examples of the style, the Anglican cathedrals in Sydney, Melbourne, Brisbane, Adelaide, and Hobart, being especially noteworthy. The Roman Catholic cathedral in Sydney is also excellent, and when completed will probably take pride of place on account of size and site; though the site is rivalled by that of the Anglican cathedral at Brisbane, a prominent rocky ridge above the river. On the other hand the Anglican cathedral at Adelaide is beautifully situated in the park-like valley of the Torrens. Numbers of churches dot the country, some good, others poor in design, but nearly all in the Gothic style. As far as educational buildings are concerned the university of Sydney, especially the great hall, is easily the most distinguished example of Gothic design, though many others show much merit. In such structures the unsuitability of the style to modern requirements, under Australian conditions of climate, are more apparent than in churches, where sentiment plays so large a part in the architectural style adopted.

This raises the question how far the modern architecture of Australia truly corresponds to the conditions of life amongst the people, as modified by climate and the materials available for building. So far no definite departure from British or American examples has been made, except in the greater use of verandahs. In a sunny climate these are a necessary feature, and should form the keynote of any design in which they are introduced, instead of being treated as mere addenda. For instance, if all the business streets of a city were arcaded on a plan resembling that of Bologna in Italy, a striking improvement would be effected, and one step taken towards a distinct and characteristic Australian style.

The adoption of new materials also gives scope for specialization in design; for instance flat instead of sloping roofs are quite permissible where snow is almost unknown; and are most advantageous both in city business buildings as open-air resorts for the employees, and in the suburbs for sleeping out. But so far no distinct treatment has been evolved in which this feature controls the general design, as it must necessarily do if the architecture is to be expressive of the conditions. Another factor which should have a material influence on design is the use of reinforced concrete, instead of building up a structure out of thousands of separate bricks or stones. The standardization of production, so characteristic of modern industry, will also tend to make the repetition of similar parts a feature of the architecture of the future.

Armstrong, HELEN PORTER. See MELBA, DAME NELLIE.

Arsenic. Arsenic ore is widely distributed in Australia, but has been worked to a limited extent only. In Victoria the deposits are usually of arsenopyrite; a small quantity of arsenic has also been obtained from the flues of roasting furnaces at Ballarat. In New South Wales about 200 tons were obtained in 1910 at Howell in the New England district, and deposits have been also located near Tumut in the south, and Burrowa west of Goulburn. During 1917 the price of arsenic was very high, and supplies were urgently needed in connection with the destruction of prickly pear; consequently the known deposits were more systematically exploited, and search was made for new deposits. The government of Queensland at once reserved from sale a large area of arsenic-bearing country at Jibbinbar near Stanthorpe on the New South Wales border, and private enterprise opened mines about 20 miles away at Beecroft in the border range. The ore of the Stanthorpe district is reckoned 99 per cent pure, and the supply is unlimited. In South Australia arsenic-bearing minerals are worked near Adelaide, at Manna Hill on the way to Broken Hill, and on Kangaroo Island. The Western Australian output is very variable; in three successive years the exports were 1765 tons, 7 tons, and 1075 tons.

Art. The history of art in Australia falls naturally into three periods, of which the first is a mere prologue. Although it includes the work of Watling and Lewin, it was in the main a period of visiting artists, usually attached to one or other of the ships sent to Australia on voyages of exploration. The second period may be said to begin in the early thirties, when the influx of free and moneyed settlers made it possible for an artist to earn his living by making pictures of the rich men's homes and teaching their daughters to paint, elegantly if vaguely, in water-colour. The third period—that of the rise of one or more schools of Australian-born artists—began as recently as the eighties of last century.

On the staff of Joseph Banks in the *Endeavour* were two young artists, Alexander Buchan, landscape and figure painter, and Sydney Parkinson, natural history draughtsman. Buchan unfortunately died at Tahiti on 17 April 1769, and Parkinson confined himself almost entirely to the technical work for which he was engaged, making 280 finished drawings, 675 sketches of plants and animals, and only one drawing of a place or event—the well-known 'Two Natives of New Holland Advancing to Combat.' Phillip's, White's and Hunter's journals contain illustrations of little value, though there is in Hunter's journal an interesting engraving of Sydney Cove reproduced from a water-colour drawing by Lieutenant Bradley. The illustrations to Collins's *Account of the English Colony in New South Wales* were redrawn in England from sketches made, probably, by an artistic convict; there were several in the colony at the time, the two best known being Thomas Watling (q.v.) and John Eyre. Among visiting artists may be mentioned C. A. Lesueur and Nicolas Petit of the Baudin expedition, and William Westall, who accompanied Flinders in the *Investigator* and whose drawings were used to illustrate Flinders's *Voyage to Terra Australis.* The most famous was Augustus Earle, who in the course of much travel spent the years 1825-8 in Australia and New Zealand. and attempted to return in 1831 as artist aboard the *Beagle*, but had to be put ashore in Uruguay on account of ill-health. Harden Melville in 1843 painted landscapes in northern Australia as artist aboard H.M.S. *Fly*: and in 1847-50 a man afterwards more celebrated in other pursuits, Thomas Henry Huxley, was artist as well as surgeon aboard H.M.S. *Rattlesnake.* Another visitor of note was Charles Meryon, the etcher, who in 1842-6,

as an officer in the corvette *Le Rhin*, made a few sketches of scenery and animals on the Australian and New Zealand coasts which he afterwards worked up into etchings.

Precursors of the second period, in that they settled in Sydney and attempted to earn a living by painting and teaching, were J. W. Lewin (q.v.), who resided in Sydney from 1800 to 1819; Robert Read senior, who opened an art school in Pitt-street in November 1814, painted Michael Robinson the 'poet laureate' of the colony in 1821 and Macquarie in 1822, and seems to have abandoned art for agriculture about 1829; and Robert Read junior—apparently unrelated to the other Read—who reached Sydney in 1819 and was still at work in 1849. This Read occasionally spelt his name 'Reid.' But the epoch of resident artists really begins with the arrival in 1831 of John Glover (q.v.), who settled at the age of 64 on a station near Ben Lomond in Tasmania, and went on painting until his death in 1849. One of his pictures is in the National Gallery, London, another in the Melbourne Art Gallery; others are in a municipal gallery at Launceston, Tasmania, and in private collections in that island. The Tasmanian group of early artists includes also Thomas Bock, who worked in Hobart as a portrait painter and engraver from 1825 to 1854 (some of his work is reproduced in Fenton's *History of Tasmania*); Benjamin Duterreau (1767-1851), who migrated to Western Australia in 1832, went on to Hobart, and became the friend both of Governor Arthur and of G. A. Robinson the protector of aborigines; and the notorious poisoner and forger, but excellent artist, Thomas Griffiths Wainewright (q.v.).

Conrad Martens (q.v.) was the second notable artist to settle permanently in Australia. As he was only 34 years old when he reached Sydney, his influence on local art was much greater than that of the veteran Glover. A student under Copley Fielding, he was an accomplished painter with a fine sense of colour and composition, but was inclined to see Australia with English eyes, his treatment of the landscape being usually rather low in tone. Owing to the difficult conditions under which artists worked in the early days, he and others were often forced to become topographical, a painting of some familiar view having a better chance of being sold than a landscape that in itself might be more beautiful and better painted. Martens had a tendency to idealize his subjects; he had also a real sense of beauty, and his best work has an abiding interest. His is the most important contribution to landscape painting in Australia up to the advent of Buvelot in 1865. John Skinner Prout (q.v.) who lived in Australia from 1840 to 1850, was also forced to produce sets of views; but in his best work there is a freshness of treatment and a glow of colour that makes his landscapes (which are usually sunnier than those of Martens) very attractive. Interesting himself in the social life of Sydney, he endeavoured to foster a taste for art there by giving a series of lectures at the Mechanics' Institute. In 1844 he lectured in Hobart, and in 1845 promoted there the first exhibition of pictures held in Australia. He is worthy of his niche, known as 'Prout's Corner,' in the National Gallery at Sydney.

Frederick Garling, who came to Sydney as a child in 1815 and is said to have painted every vessel that arrived in Port Jackson between 1830 and 1870—as he was landing-master, he had enough opportunities—was probably the first Australian marine painter. But the first of any standing was Oswald Brierly (q.v.), a facile wielder of the brush, whose energy and enterprise enabled him to paint a wide variety of subjects during his two visits (1842-50 and 1867-8). As a depicter of the movements of vessels in storm or calm he excelled. His output was remarkable: over 200 of his sketches and paintings are in the Mitchell Library at Sydney. George French Angas (q.v.) is best known as the illustrator of several volumes concerned with the scenery, aborigines, etc., of Australia and New Zealand in the forties, and of the Australian goldfields in 1851: the art gallery at Adelaide has over 180 of his paintings and drawings.

Marshall Claxton reached Sydney in 1850 with a commission from Miss (afterwards Baroness) Burdett-Coutts for a large mural decoration, 'Suffer Little Children to Come Unto Me,' for the infants' class-room in the school attached to the Church of St. Stephen, Rochester Row, Westminster. It was the first large figure composition painted here, and Charles Dickens described it fully when it was subsequently shown in a gallery in Pall Mall (in an article on 'Fine Arts in Australia,' published on 13 March 1852). The first woman painter to attract attention at home and abroad was Adelaide Ironside, born in Sydney on 17 November 1831, whose work won for her the friendship of Daniel Denichy and inspired the eulogies of Francis Adams and Brunton Stephens. Going to Rome in 1856, she devoted herself to painting religious subjects, but died on 15 April 1867, just when her reputation was becoming assured.

In the fifties an interesting group of painters and sculptors settled in Victoria. At the 1857 exhibition of the Victorian Society of Fine Arts in Melbourne works were shown by Nicholas Chevalier (q.v.), the first cartoonist on *Melbourne Punch*, and by Eugene von Guerard, son of the court painter to the Emperor Francis I of Austria. J. A. Gilfillan exhibited 'Captain Cook Taking Possession of New South Wales,' the first of our historic pictures; and William Strutt, the painter of 'Black Thursday,' was represented. The work of two women artists also attracted attention—a set of miniatures being shown by A. M. McCrae, and a medallion by Margaret Thomas, our first woman sculptor. Mrs. McCrae, who arrived in Melbourne in 1841, had been a favourite pupil of John Varley; she was the mother of George Gordon McCrae (q.v.). The various phases of the gold-rush period are preserved for us in the lithographs and water-colours of S. T. Gill (q.v.), a clever craftsman whose intimate glimpses of life in the roaring fifties have an inestimable historic importance.

The sculpture of this period begins with the work of Charles Abrahams, who worked in Sydney in 1843-9; among his works was the first piece of sculpture—a bust—carved from Australian marble (see MITCHELL, SIR T. L.). Abrahams was the forerunner of a much greater sculptor, Thomas Woolner, R.A., who during his visit to Australia in 1852-4 modelled medallions of many prominent citizens of Sydney and Melbourne, and some years later made the statue of Captain Cook that now stands in Hyde Park, Sydney. In Melbourne the most prolific sculptor of the time was Charles Summers, resident there from 1853 to 1866: his most important work was the Burke and Wills group that for many years stood in Collins-street on the brow of its eastern hill, and is now in Nicholson-street. It was the first bronze statue cast in Australia.

During the seventies the sculptor A. Simonetti and the portrait-painter Giulio Anivitti figured prominently. Both were instructors at the New South Wales Academy of Art, and were employed by public bodies and the government on busts and portraits of the notable men of the day. Simonetti's statue of Governor Phillip stands in the Sydney botanic gardens, and Anivitti's portrait of Charles Badham (q.v.) hangs in the Great Hall at the university of Sydney.

The third period of artistic development, though it can hardly be said to begin until the eighties, is closely connected with the work of Abram Louis Buvelot, a Swiss painter who, after spending some years in South America, in 1865 settled in Victoria and began to paint landscapes. Three of his works now in the Melbourne gallery—'Waterpool at Coleraine,' 'Winter Morning at Heidelberg,' and 'Summer Evening near Templestow'—show him as an artist with rare vision, who had the technical skill to convey his spacious impressions on canvas. His influence on the younger Australian painters was considerable; Streeton, Roberts, Patterson, McCubbin, Mather and others, have all acknowledged him as the 'father' of landscape painting in Australia. A court in the Melbourne art gallery is named after him, and his bust by Mackennal is in the collection. The first Australian-born landscape painter was W. C. Piguenit, who was sketching in Tasmania in the fifties. One of his best-known works is 'Mount Kosciusko' in the Sydney gallery.

With the eighties emerges a genuinely Australian group of painters, most of them Victorians. There was still little demand for the work of local men, but in 1885 Tom Roberts, Fred McCubbin and Louis Abrahams established an artists' camp near Box Hill; moving in the summer of 1886 to Mentone on the shores of Port Phillip, they were joined by Arthur Streeton. In 1887 Roberts while on a visit to Sydney met Charles Conder, and in 1888 Roberts, Conder and Streeton established a camp at Eaglemont, which overlooked the valley of the Yarra near Heidelberg. There during 1888-90 they painted impressionist landscapes—Roberts had fallen in love with impressionistic methods during a visit to Europe in 1881-4, and the sketches he brought back set his comrades on the same path. The result was first made public at the historic 'Exhibition of 9 x 5 Impressions' held in Melbourne in August 1889 ('9 x 5' are the dimensions in inches of the lids of a brand of cigar-boxes, on which most of the 'impressions' had been painted). The exhibition greatly pained the art-critics of the day, but the proceeds enabled the artists to pursue their career. In April 1890, however, Conder went to England, and the Eaglemont camp was broken up. Conder diverged into fan-designing, and has affected no artist in Australia except (much later) Thea Proctor. Roberts turned his attention mainly to portrait-painting, though his 'Golden Fleece' (in the Sydney gallery) and his 'Break-away' (in the Adelaide gallery) are fine records of pastoral life. But the influence of Streeton did a great deal towards the founding of an Australian school of landscape painting. He was the first to translate into paint the blue of Australian skies and the clear transparency of Australian distances; when in 1892 he began to work in Sydney, the local artists learnt for the first time (so one of them, Lister Lister, declared) how bright were the colours and how clear the atmosphere of the landscapes they had been accustomed to depict in low tones. Among his immediate comrades and followers in landscape work were David Davies ('A Summer Evening' and 'The Moonrise'), Walter Withers ('Tranquil Winter'), J. Ford Paterson ('The Dawn of Night' and 'A Bush Symphony'), W. Lister Lister ('Banksias'), and Sidney Long ('The Spirit of the Plains').

Another notable artists' camp took the place of Eaglemont. Walter Withers, who had joined the Eaglemont trio after their exhibition, rented Charterisville, a neighbouring house in the Yarra valley, and many young artists at one time or another camped in the grounds, including E. Phillips Fox, Max Meldrum, Will Dyson, John Shirlow, and Lionel and Norman Lindsay.

In Sydney also the last two decades of the century saw an outburst of artistic endeavour, largely inspired by the compilation of the *Picturesque Atlas of Australasia* and the rise of the *Bulletin*. The most important work for these publications was done by imported artists—Phil May and Livingston Hopkins for the *Bulletin*, for the *Atlas* F. B. Schell, W. T. Smedley and W. C. Fitler; but among local artists were employed Julian Ashton, Frank Mahony, A. H. Fullwood, William Macleod and Ellis Rowan; and Charles Conder and B. E. Minns were busy with work for the *Illustrated Sydney News*. All the artists just named made, apart from their black-and-white work, definite and valuable contributions to Australian art, and most of them are dealt with under their names elsewhere in this encyclopaedia, but the work of Julian Ashton was of a special kind; a born leader and a teacher of unqualified sincerity, he both trained and inspired his pupils to follow high artistic ideals, and fought their battle against public and private indifference until the status of the artist in Australia has been placed beyond attack and secured against neglect.

Side by side with Streeton's school of landscape there was growing up, probably instigated, if not inspired, by the commercial demand for illustrative black-and-white work, a school of artists who employed themselves largely in depicting phases of Australian life. Frederick McCubbin—whose best work includes 'On the Wallaby' in the Sydney gallery, 'A Bush Burial' at Geelong, and the noble 'Pioneers' in the Melbourne gallery—was the first to visualize the struggles of the early settlers. The work of Tom Roberts in this category has already been mentioned, and with it must be placed George Lambert's 'Across the Blacksoil Plains,' one of the best-known pictures in the Sydney gallery. Frank Mahony devoted himself mainly to horsemanship and horses; his 'Rounding-up a Straggler,' bought by the Sydney gallery in 1889, and 'The Cry of the Mothers' (1896), are still unique of their kind, and his sketches for the *Atlas* included a number of little masterpieces.

All this activity naturally resulted in the formation and development of art societies. The oldest existing society of this kind is the South Australian Society of Arts, which was founded as far back as 1856. In Sydney an Academy of Art (for which see ART GALLERIES) was founded in 1871, and the Art Society of New South Wales was founded in 1880 by Arthur and George Collingridge; it became 'Royal' in 1907. A Victorian Academy of Art, founded in 1870, was in 1888 reconstituted as the Victorian Artists' Society. In 1895 a number of professional members of the Art Society in Sydney seceded from the main body to become the Society of

Artists: under official pressure this body rejoined the parent society in 1902, but again broke away in 1907. The Australian Art Association was initiated in Melbourne in 1912, and the Australian Painter-Etchers' Society in Sydney in 1920.

In recent years Hans Heysen of South Australia has further developed the rendering of Australian landscape, paying particular attention to the dignity and beauty of eucalypts either singly or in forests: he employs many media, and of late has produced flower paintings of exceptional quality. Among other landscapists J. J. Hilder—the most delicate colourist since Conder—and Blamire Young are in no way derivative; Elioth Gruner's impressions of early morning light, and Max Meldrum's low-toned renderings of bush scenery, call for special mention; and it should be noted that Penleigh Boyd, who was accidentally killed when only 33, was on his way to doing for the wattles what Heysen has done for the eucalypts. In portraiture Lambert and Longstaff, Quinn, Coates, Meldrum, and McInnes, with Hugh Ramsay and E. Phillips Fox, stand out above a large number of followers whose performances are creditable. The only analogue to the post-war 'modernists' of Europe is a small group of which Thea Proctor, John Moore, Margaret Preston and Roland Wakelin are the principal figures. Among marine painters may be classed David Davies, Will Ashton, Charles Bryant, and A. J. W. Burgess.

In 1885 Livingston Hopkins, Julian Ashton, and Henry Fullwood, with a few others, initiated the practice of etching; a few prints had previously been made in Australia, notably by John Mather, but the movement of 1885 was the first sustained attempt to introduce the art. For another twenty years, however, little progress was made. The first of the younger group to adopt this medium was John Shirlow, a Victorian, whose etching 'The Sawmill' prompted Lionel Lindsay to revive the art in Sydney. Lindsay's first prints were shown at the exhibition of the Society of Artists in 1907. Slowly the new movement grew, encouraged by the success of Sydney Ure Smith and Bruce Robertson and the sensational work of Lionel Lindsay's brother Norman—a real but unbalanced genius, who has produced not only a long series of striking etchings and some delicate water-colour drawings, but some of the most remarkable pen-drawings ever exhibited. In 1921 the first exhibition of the Australian Society of Painter-Etchers displayed the work of nineteen members, and the popularity of the art is shown by the fact that the society's sales now considerably exceed those of the Royal Society of Painter-Etchers in London.

Sculpture is an art of comparatively late development in Australia, and until recently lacked local encouragement, so that most sculptors of Australian birth preferred to work in a European milieu. Mention has already been made of several visiting sculptors of the gold-rush period; to them may be added Lucien Henry, a Provençal pupil of Viollet-le-Duc, who fled from Paris in 1871 after an unfortunate connection with the Commune of that year, and became a member of the teaching staff of the Sydney technical college. There he developed the use of the Australian flora and fauna as a base for decorative architectural design, employing the lyre-bird to adorn capitals, the seahorse for bowls, and various foliage-plants for panels. In this direction he has had few followers, if any, but his influence on Australian sculpture was definite and good. The most notable Australian sculptor of the present day is Sir Bertram Mackennal (q.v.). Harold Parker's best work is the beautiful 'Ariadne' which was bought by the Tate Gallery. Web Gilbert (q.v.), with a long array of portrait busts and imaginative works to his credit, is the official sculptor to the Australian War Museum. Nelson Illingworth has also specialized in portrait busts. George Lambert, the most versatile of Australian artists, has essayed sculpture at times with considerable success, especially in a war memorial for Geelong and a design for the war memorial at Port Said. Probably the most typical Australian work is that of Douglas Richardson, including 'Pioneer,' 'The Mirage,' and 'The Discovery of Gold.' A small group of women sculptors includes Dora Ohlfsen, Theo Cowan, Margaret Baskerville and Eva Benson.

In 1924 a school of sculpture was opened at the technical college in Sydney under the superintendence of G. Rayner Hoff, a former winner of the Prix de Rome.

The first Australian artist to receive a European award was Rupert Bunny, who in 1890 gained a *Mention Honorable* at the Paris Salon; Longstaff was similarly honoured in 1891, and Streeton in 1892. The first medallist at this Salon was E. Phillips Fox. Of the New Salon Phillips Fox, Rupert Bunny and Bessie Davidson were elected sociètaires and George Lambert and George Coates associates. Mackennal is a R.A., Lambert an A.R.A.: Mackennal, Parker and Gilbert are all represented in the Tate gallery, and Rupert Bunny and Charles Conder in the Luxembourg. In 1915, it may be noted, the exhibition at the Royal Academy included pictures from every State in Australia: 24 artists in all were represented, of whom six had pictures hung 'on the line.' A small exhibition of Australian pictures was held in London in 1898, and a more important one in 1923.

See ART GALLERIES, under which heading the most important pictures in each gallery are enumerated. The best aid to a study of Australian art is the series of monographs and articles embedded in *Art in Australia*, and the separate volumes (issued by various publishers) on Conrad Martens, J. J. Hilder, Arthur Streeton, Blamire Young, Hans Heysen, George Lambert, F. McCubbin, and Penleigh Boyd. W.M.

Artesian Water. Australia is notable for the great extent of its artesian-water-bearing areas, which occupy (roughly) 950,000 square miles out of a total of 3,000,000. As at present defined, there are six basins more or less developed, and a small undeveloped basin east of Wyndham on Cambridge Gulf. The six are:—

		AREA sq.miles
1.	The Great Artesian Basin	602,000
2.	The Murray River Artesian Basin	107,200
3.	The Eucla Artesian Basin	74,300
4.	The Coastal Basin of Western Australia	10,500
5.	The North-west Basin of Western Australia	40,500
6.	The Desert Basin of Western Australia	115,000

Of these the first-named is by far the most important and most interesting.

1. The Great Artesian Basin extends from the Gulf of Carpentaria in northern Queensland southwards into New South Wales and South Australia—as far south, in fact, as 32° S. lat. Recent investigations by Sir Edgeworth David go to show that the northern part of this basin

(from Cloncurry northwards) is a separate basin draining to the Gulf, whereas the main basin drains towards Lake Eyre.

The principal water-bearing strata are of Trias-Jura age, and consist of porous sandstones of freshwater origin, resting uncomformably upon a series of highly-folded lower Palaeozoic strata, which form the necessary underlying impervious layer. Overlying the water-bearing strata is a series of more or less horizontal layers of marine shales, sandstones and impure limestones of Cretaceous age; these, taken as a whole, form the upper impervious layer necessary to give artesian conditions. The intake-beds for this basin have, at altitudes of as much as 2000 feet, but over the greater part of the basin the surface of the country is only a few hundred feet above sea-level. The floor of the basin is very uneven; a partly buried ridge, which extends from near Charleville in Queensland to Bourke in New South Wales, divides the southern part of the basin into two very unequal parts—an eastern portion with a maximum depth of 3000 feet, and a western portion with a depth of 4500 feet at Bimerah in New South Wales, and perhaps as much as 5000 feet in South Australia. In northern Queensland there is a broad upward bulge extending from Cloncurry eastwards to Saxby

along its eastern and south-eastern margins, a thickness of about 2500 feet, and outcrop along the western side of the main tableland belt up to altitudes of 2000 feet. Followed westwards, they dip rapidly below the western plain to 3000 and 4000 feet (or even more) below sea-level. Along the southern and western margin of the basin these outcrops are hidden, for the most part, by more recent deposits. That the main water-bearing beds over this basin are Trias-Jura age is shown by the fossil plants (such as *Taeniopteris diantrcei* and *Thinnfeldia odontopteroides*) obtained from the bore-cores. The artesian water which occurs in porous layers in the overlying Cretaceous formations is relatively unimportant in quantity.

Water-bearing strata are known to outcrop Downs, over which the floor of the basin is in places less than 500 feet deep, the depth to the northern side increasing rapidly to 3500 feet, and on the southern side increasing less rapidly to 2500 feet below sea-level. As stated above, it is probable that this bulge actually separates two basins.

The temperature of the bore water varies very much in different localities, but in all cases is much higher than one would expect for water derived from undisturbed sedimentary strata. The water from Elderslie No. 2 bore in Queensland (depth 4523 feet) reaches the surface with a temperature of 210° F.; Goyder's Lagoon bore in South Australia (depth 4550 feet) has a temperature of 208° F. Over large areas the temperature-gradient ranges from 1° F. in 30 feet,

to 1° F. in 22 feet, and in some cases even steeper gradients have been found. There are, however, wells with a more normal gradient, e.g. a well near Walgett in New South Wales with a gradient of 1° F. in 70 feet; but such low gradients are uncommon. The increase of temperature with depth is also not by any means regular in individual wells. For example, in the Mirra Mitta bore in South Australia the temperature of the water increased from 122° F. at 3485 feet to 176° F. at 3506 feet, while at 3534 feet it rose to 190° F. In bores that have been re-examined after flowing for some time the temperature has sometimes decreased, sometimes increased—in one case by as much as 10 degrees in two years.

Water from all bores in the Great Artesian Basin is strongly alkaline. Analyses of the salts from four widely-separated bores in New South Wales are as follows:—

Sodium Carbonate	32.63	40.00	38.34	17.37
Potassium Carbonate	1.70	—	trace	6.61
Calcium Carbonate	0.50	1.12	1.21	1.55
Magnesium Carbonate	0.12	trace	0.26	1.93
Sodium Chloride	7.25	6.91	7.23	9.55
Sodium Sulphate	—	—	0.86	—
Silica	1.76	—	1.96	1.43
Total solids in grains per gallon	43.96	48.03	48.86	39.99
Total solids in 1000 parts	0.63	0.68	0.69	0.57

The water is, therefore, of the alkaline carbonate type, the most abundant constituent being sodium carbonate, which accounts for nearly 80 per cent of the total solids. Comparing these analyses with those of artesian waters from other basins, we may note the general absence of sulphates, the relatively small percentage of sodium chloride, and the small percentage of potassium and calcium carbonates. The mineral content, however, is well below that which would render it unfit for consumption by stock, for which purpose it is very largely used, thus making available for pastoral purposes large areas that would otherwise be practically useless in most seasons. In some places the water has been used for irrigation purposes; but this, if continued, charges the soil with alkali, so that its irrigational value is not great. The bore water brings to the surface not only solids in solution but also considerable quantities of gases, including nitrogen, carbon dioxide, methane, and (occasionally) a little oxygen; the methane is probably derived from the coal-seams known to occur in the artesian series. Nitrogen is the most abundant of the gases given off; as to the source of this gas there is considerable difference of opinion.

The total daily flow from the wells in this basin is probably not less than 700 million gallons. The largest flow obtained from any one well was 2,333,000 gallons per day (from the Yarmouth bore in Queensland); many wells when first sunk gave flows of over 1,000,000 gallons per day. Unfortunately after a time the flow, in all cases, begins to decrease; careful observation in New South Wales places this decrease in some cases at six to seven per cent per annum. Consequently in recent years attention has been directed especially to the probable origin of the water. Until a few years ago it was generally believed that the supply was derived directly from rainfall on the intake-beds, and that water removed from the bores would be rapidly replaced by rain-water—in other words, that the water has a 'meteoric' origin, being derived from the atmosphere. The evidence in support of this theory was as follows:—

(*a*) The area within which the wells occur is a true artesian basin, and nearly everywhere within it the water is under sufficient pressure to rise to the surface when a bore-hole is put down.

(*b*) The intake-beds outcrop over a sufficiently large area, and are sufficiently porous, to gather the necessary supply of water from rainfall.

(*c*) The intake-beds outcrop at a sufficient altitude (on the eastern side of the basin) to give the necessary hydraulic grade.

This theory was first challenged in 1906 by Professor J. W. Gregory, who maintained that many of the observed facts were opposed to this explanation, and argued that the greater part of the water in this artesian basin was of 'plutonic' origin—i.e. that it had been derived from the interior of the earth, and not from the rainfall. The importance of this view lay in the implication that, instead of the supply of water being constantly replenished by rain-water, there was probably a definite limit to the amount of water actually available.

Some of the factors difficult to explain under the meteoric hypothesis, but capable of explanation under the plutonic hypothesis, are:—

(*a*) The unusually high temperature-gradient found in most of the wells.

(*b*) The very irregular increase of temperature with depth in some of the wells.

(*c*) The peculiar salinity of the water, and the variation of salinity which occurs in different parts of the basin; also the occasional presence of boric acid.

(*d*) The nature and amount of dissolved gases.

(*e*) Anomalies in the arrangement of the isopotential lines, which in some places suggest that the water is flowing in a direction incompatible with the meteoric theory.

Even if the origin of the water is meteoric, it is still doubtful whether percolation from the intake-beds is rapid enough to maintain the supply against the demands now being made upon it. A. L. Du Toit of South Africa has recently arrived at the conclusion that none of the present rainfall over the intake-beds will become available within the basin, even along its margin, until after the lapse of centuries, and that, though most of the water at present stored in the basin is of meteoric origin, it was stored there during previous geological periods.

2. The Murray River Basin is situated in southern Australia along the lower course of the Murray River. It has an area of 107,200 square miles, divided between Victoria, New South Wales and South Australia. Over most of this area the water is sub-artesian—that is, not under sufficient pressure to make it rise to the surface. It is met with at a depth of 80 feet to 100 feet, and is pumped to the surface by windmills. Sometimes it is slightly brackish. The strata in this region are of lower Tertiary age (lower Miocene) and consist of horizontal layers of sandstones, shales, and limestones. Recently true artesian water has been obtained in this basin from bores put down on Belmore and Lake Victoria stations in the New South Wales section. The water (which is slightly saline, but is suitable for stock) was struck at depths of from 600 to 700 feet; it rises a few feet above the surface, and the flow varies from 50,000 to 100,000 gallons a day.

3. The Eucla or Nullarbor Basin lies along the shores of the Great Australian Bight, extending 400 miles east from Israelite Bay and about 200 miles inland. Its area is about 74,300 square miles, mainly Tertiary limestones

resting upon what are probably Cretaceous marine beds. The water is for the most part sub-artesian, a saline quality being struck at 900 feet and a much fresher quality below that depth. In some cases (e.g. the Madura bore, 2000 feet deep) the water rises to the surface. It has been found that horses thrive on water containing 1 oz. of salts to the gallon, while cattle can stand 1½ oz. and sheep 2 oz.—even 3 in a dry season.

The South Australian government is having bores put down in an area between the Eucla and the Great Australian basins bounded by the transcontinental (east-west) railway, the 132nd meridian and the boundary of the Northern Territory The first bore lies west of McDouall Peak.

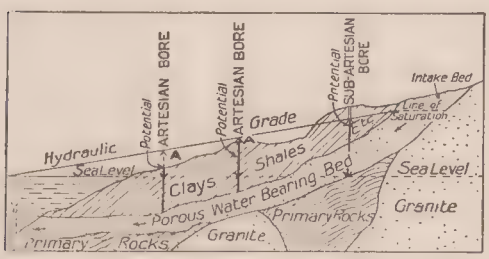
4. The Coastal Basin of Western Australia is a long, narrow artesian basin parallel and adjacent to the southern part of the western coast of Western Australia, and extending from Geraldton almost to the southern coast. It yields a fairly abundant supply of artesian water. Geologically it consists of recent dune rock resting upon gentle dipping cretaceous marine strata, which in turn rest upon Permo-Carboniferous strata. Interdependence between the rainfall and the outflow of artesian water in this basin appears to have been definitely proved.

5. The North-west Basin of Western Australia extends from Gantheaume Bay to Onslow. About 69 bores have been put down, and from one of them a flow of nearly 3,000,000 gallons per day was obtained, though the bore is only 300 feet deep.

6. The Desert Basin of Western Australia, which extends from a little east of the De Grey River to beyond Derby, and for a long distance inland, is hardly developed at all, and its boundaries are still uncertain. The area assigned to it at the beginning of this article is therefore a mere approximation. C.A.S.

Economic Uses.—Over a large proportion of Australia the average rainfall is less than 15 inches per annum, and any adequate system of water conservation from surface supplies is impracticable. In the settlement of such regions artesian water, where available, plays a most important part, and bore-drains, fed with a constant stream from the bore-head and reticulated through large areas of pastoral property, have during droughts saved very large numbers of stock.

Problems connected with this artesian water were discussed by inter-State conferences of geologists and engineers in 1912, 1914, 1921, and 1924. The accompanying diagram, taken from the



Generalized Section of an Artesian Basin, with an outlet to the ocean.
A—Height corresponding to observed pressure.

report of the 1914 conference, shows the conditions existing in a typical artesian basin with an outlet to the ocean.

Boring Plant.—Artesian water was first discovered in 1879 at Kallara station in the north-west of New South Wales. In sinking some of the earlier bores diamond-drill and calyx plants were used, but the types usually adopted were the Canadian pole rig and the cable rig with Manilla rope. Modern plants are of the cable type, with wire rope and side cutting-tools; this avoids the under-reaming required with the earlier type of straight bit, and the cost of boring is thus much reduced. The most modern plants are fitted with hydraulic rotary attachments, in place of percussion tools, for working in shale or soft strata. The bore-hole is lined with steel swelled-joint casing, in several strings. In properly cased bores the first string, usually 10 to 12 inches in diameter, is sunk to a depth of several hundred feet below the surface; inside it is sunk the second string, of 8 inches' diameter; this is carried down to a hard stratum, and firmly seated by driving it into a smaller hole cut with a straight bit. In some recent bores it is cemented in. The inner string, usually 6 to 6½ inches in diameter, is then taken to the bottom of the bore, and perforated opposite to the water-bearing strata; where there is no danger that the strata will cave in, the casing may be partly withdrawn and suspended above them. In bores where, on account of the great depth or other reasons, difficulty is experienced in drilling, there may be a fourth string of casing, 5 inches in diameter. The strings of casing are closed at ground-surface by a head-piece, fitted with a valve for controlling the flow. Discharge is made into an excavated basin, from which lead the bore-drains, suitable divisors being provided for distributing the flow as required. The drains are small channels, constructed with a delver, and in the case of many bores have an aggregate length of from 40 to 80 miles.

Diminution in Flow.—In order to prevent waste of water it is most desirable, where the bores are properly cased, that the flow be shut off, or partially so, when not required; unfortunately the defective casing of most of the earlier bores does not admit of this. The importance of preventing waste is emphasized by the general diminution in the artesian flow. For example, in two districts of New South Wales (each approximately 11,000 square miles in area) where regular observations are taken, it has been found that the recent decrease in flow is in one case about 2.4 per cent, in the other about 6.5 per cent, per annum. In the second district the decrease is partly due to corrosion of the casing in some of the bores; but the main reason, doubtless, is the drain on the basin due to the multiplication of bores, which are here much closer together. Of 977 flowing bores in Queensland 124 had been remeasured up to 1914; these in 15 years showed a decrease of 40 per cent in their aggregate flow.

The conference mentioned above recorded its opinion that the primary cause of the diminution in flow in Queensland and New South Wales is the overdraft which has already been made upon the accumulated supply of the Great Basin by the undue multiplication of bores, and urged (*a*) that future bores should be sunk only at sites where the surface-level will admit of the supply being used without waste, and (*b*) that they be properly constructed and cased, so as to admit of closing them when the supply is not required.

Corrosion of the casing has given trouble in the Coonamble district in New South Wales, and also in parts of Queensland. The cause

of the corrosion is being investigated, but no conclusion has yet been arrived at. In a bore sunk some years ago at Coonamble the casing was lined with oregon staves one inch thick as a protection against corrosion; in a more recent case in the same locality a cement lining two inches thick was forced in by pumping from the bottom between two strings of casing.

Utilization.—Artesian water is used to a small extent for town supplies, and for the production of power (by means of Pelton wheels and other hydraulic prime movers) for operating sheep-shearing, lighting and other plants; but its principal use is for pastoral purposes. When running streams are not available on a station, supplies of water are usually obtained by sinking tanks and wells; this makes it necessary for stock to travel long distances to water, trampling and destroying on their way large quantities of feed. On the other hand, in country watered by artesian bores the water is carried to the stock in a running stream for miles through the paddocks, and the carrying capacity is correspondingly increased.

At Moree in New South Wales, on the south-eastern edge of the Great Basin, a bore 2800 feet deep provides 600,000 gallons per day, which supply thermal baths for those suffering from muscular or nervous diseases. The surface temperature of the water is 109° F. and that of the main bathing pool 100°.

Statistics for 1923.—

State	Flowing bores public	Flowing bores private	Daily flow in million gallons	Maximum depth in feet	Maximum temperature
New South Wales	133	251	83	4338	139°F.
Queensland.....	86	1201	399	7009	210°F.
South Australia..	42	no record	16	4850	208°F.
Western Australia	108	90	58	3400	140°F.

Practically all Victorian bores are sub-artesian. Tasmania has none. In the Northern Territory one bore is artesian. In these statistics, which are the latest available, sub-artesian and pumped supplies are not included.

H.H.D.

Art Galleries. The first public art gallery in Australia was opened by Sir Henry Barkly on 24 May 1861 on the ground floor of the north wing of the Melbourne public library: its contents consisted almost entirely of casts of statues and *bassi relievi*. In October 1863 a commission appointed by the legislature to consider the promotion of the fine arts in Victoria recommended the formation of a public gallery and school of art, and on 24 December 1864 a picture gallery was opened on the first floor of the north wing, and £2000 was voted by parliament for the purchase of pictures in England, besides £200 for a picture by a local artist: the picture selected was Chevalier's 'The Buffalo Ranges.' In 1866 an intercolonial exhibition was held in the library grounds, and the pictures were re-hung in a temporary gallery on the site of the present Verdon gallery. In 1869 an exhibition of works of art, etc., produced a balance of £450 which became the nucleus of the travelling scholarship fund, and on 29 December (in accordance with the final report of the commission mentioned above) the public library, museums, and national gallery of Victoria were by act of parliament incorporated under 15 trustees (see LIBRARIES, PUBLIC). In 1873 the building of a new picture gallery (now the Macarthur gallery) was begun, and on 24 May 1875 the gallery was opened to the public. Meanwhile in 1870 Eugene von Guerard had been appointed head of a school of painting (with six students) and Thomas Clarke head of a school of design, with 35. These schools rapidly achieved popularity, and in five years the number of their students had increased to 41 and 152. Von Guerard was succeeded in 1882 by G. F. Folingsby, who was made 'Director of the National Gallery,' and he in 1891 by F. McCubbin (temporarily). In 1892 Bernard Hall took over the directorship. The first travelling scholarship was awarded in 1887 to John Longstaff. Among the important pictures, etc., acquired by the gallery in these early years are Lady Butler's 'Quatre Bras' (1884), Orchardson's 'First Cloud' (1887), Boehm's bronze group 'St. George and the Dragon' (1888), Turner's 'Dunstanborough Castle' (1888), Alma Tadema's 'Vintage Festival' (1888), Waterhouse's 'Ulysses and the Sirens' (1891), Streeton's 'Purple Noon's Transparent Light' (1896), and Phillips Fox's 'Landing of Captain Cook' (1902). Among the scholarship-holders since Longstaff are George Coates (1896), D. M. Meldrum (1899), Isaac Cohen (1905), and Constance L. Jenkins (1907).

Since 1904 the history of the Victorian gallery is bound up with that of the Felton bequests. In 1904 Alfred Felton (q.v.) left half his residuary estate, amounting to about £190,000, for the purchase of works of art ancient or modern, or antiquities, or other works that might be selected by a specially appointed committee and approved by the trustees of the Victorian gallery. All such purchases must be presented to the gallery and marked with the words 'Felton Bequest.' The original committee consisted of Dr. Charles Bage, F. S. Grimwade, Edward Langton, F. R. Godfrey and J. A. Levey; Professor E. E. Morris, whom Felton had nominated as the first trustee, predeceased the testator. The present trustees (1925) are Dr. Bage, J. A. Levey, E. N. Grimwade, Sir J. H. Macfarland and Dr. Alexander Leeper. The trust estate is now worth nearly £600,000, and the income available for 1923 amounted to about £22,000. No preference is given to Australian works of art, the committee considering that it has no power to allocate funds to any special department. Australian pictures, etc., are acquired by the committee and the gallery trustees acting conjointly, usually on the advice of the director of the Victorian gallery. Outside Australia selection is for the most part left to expert advisers. Of these F. W. Gibson was appointed on 23 December 1908 and retired on 31 December 1915, having had the help of Sir Sidney Colvin in 1913-5. After an interregnum caused by the war, Robert Ross was appointed adviser in November 1917, but died on 5 October 1918, and was succeeded by the present adviser, Frank Rinder. The committee has also been assisted at various times by George Clausen, R.A., Joseph Pennell, M. de Vasselot, L. Bénédite, Charles Ricketts, Percy Macquoid and D. S. MacColl.

Among the works of exceptional importance acquired by the gallery through the bequest committee are, Pissarro's 'Boulevard Montmartre,' Clausen's 'Ploughman's Breakfast,' Ford Madox Brown's 'Entombment,' and Auguste Rodin's 'Head of Jean Paul Laurens,' all bought in 1905; Corot's 'Bent Tree' (1907); Mackennal's 'Circe' (1909); J. M. W. Turner's 'Walton Bridges' (1919); Van Eyck's 'Madonna and

'Child'—the Ince-Blundell Madonna—and Van Dyck's 'Countess of Southampton' (both in 1922); Orpen's 'Chinese Shawl' (1923); self-portraits of Hugh Ramsay (1906) and George W. Lambert (1921); Raeburn's 'James Wardrop' (1925); and a series of drawings for Dante's *Divina Commedia* by William Blake (1918). There is a representative collection of Norman Lindsay's pen-drawings, and a model of Cook's ship the *Endeavour* by the same artist; two Books of Hours, the Wharncliffe and the Cobham; and a valuable collection of Chinese ceramic ware and bronzes.

New South Wales.—At a meeting held in Sydney on 25 April 1871 under the chairmanship of Thomas Sutcliffe Mort (q.v.) the New South Wales Academy of Art was formally constituted with Mort as president and E. L. Montefiore as vice-president. Premises were leased in Elizabeth-street, and classes held there under Signori Anivitti and Simonetti. In 1875 the government established and subsidized a Gallery of Art, choosing its trustees from the council of the Academy —Sir Alfred Stephen, E. L. Montefiore, Eccleston Du Faur, J. R. Fairfax and J. H. Thomas. The first purchases made for this gallery—six water-colour drawings—are now grouped together in the Sydney gallery. In the Sydney international exhibition of 1879-80 a building at the entrance to the botanic gardens was set aside for a fine arts show; when in 1880 this building was vacated, the government handed it over temporarily to the gallery trustees and voted £5000 for the purchase of pictures—a vote which was repeated annually until 1893. But the temporary gallery was insecure and inconvenient, so that almost immediately the erection of a permanent gallery was begun, and on 23 December 1885 the nucleus of the existing gallery was opened by Lord Carrington. The first of the existing courts was opened on 24 May 1897 by Lord Hampden, the whole of the southern wing and basement by B. B. O'Conor (then minister for education) on 31 October 1904, and the central façade and entrance in 1906. In 1885 the value of the collection was about £14,000: in 1924 it was estimated at £168,000, and included 526 oil-paintings, 418 water-colours, 815 specimens of black-and-white work and 177 pieces of sculpture.

Among the more notable pictures in the gallery are Millais' 'Captive' (purchased in 1885), Ford Madox Brown's 'Chaucer' (1876), De Neuville's 'Rorke's Drift' (1882), Luminais' 'Sons of Clovis' (1886), Greiffenhagen's 'Judgment of Paris' (1897), Brangwyn's 'The Scoffers' (1898), Lavery's 'The White Feathers' (1900), and Hoffbauer's 'Sur Les Toits' (1905). Mackennal's 'The Dancer' and Frampton's 'Peter Pan' are prominent in the sculpture section. Australian art is well represented with Ashton's 'Sir Henry Parkes' (1890), Streeton's 'Still Glides the Stream' (1890), Tom Roberts's 'Golden Fleece' (1894), Longstaff's 'Lady in Black' (1896) and portrait of Henry Lawson (1900), Lambert's 'Across the Blacksoil Plains' (1899), Phillips Fox's 'Motherhood' (1913), Gruner's 'Morning Light' (1916), Hugh Ramsay's 'Sisters' (1921), and Heysen's 'Flowers and Fruit' (1921). The gallery depends entirely on the State for funds —a severe handicap in times of public retrenchment—but is able from bequests to award two prizes annually. The Wynne Art prize is given for the best painting of Australian landscape or the best piece of figure sculpture; the Archibald prize goes to the best portrait (preferably of a distinguished Australian) painted by an Australian artist resident in Australia.

South Australia.—In 1880 the government of South Australia bought £2000 worth of pictures, and in 1881 a public art gallery was opened in two rooms of the public library building by Prince Albert Victor of Wales. In 1889 the gallery was transferred to the jubilee exhibition building, and in 1900 was housed in a building of its own, erected by the government with a bequest of £25,000 from Sir Thomas Elder (q.v.). Among later bequests was one of £16,500 in 1903 from Dr. Morgan Thomas; and in 1907 David Murray left the gallery £3000 in cash and a valuable collection of engravings and woodcuts. Other collections illustrate ceramics, archaeology, and Australian history and exploration, and a collection of coins (the largest in Australia) was commenced early in the history of the South Australian Institute. Among the more notable pictures in the gallery are G. F. Watts's 'Tennyson' and 'Love and Death,' Orpen's 'Marshal Foch,' Bouguereau's 'Virgin and Child,' Tom Roberts's 'Breakaway,' Waterhouse's 'Circe Invidiosa,' two flower-pieces by Fantin La Tour, and several examples of Hans Heysen. Sculpture is represented by Swan's 'Puma with a Macaw.'

Queensland.—The art gallery of Queensland began as a collection of pictures and engravings belonging to the government, several 'old masters' bequeathed by T. de M. Murray Prior, and pictures lent by prominent citizens, hung in the Brisbane town hall and opened to the public by Sir Henry Norman (then governor) on 29 March 1895. It was at first controlled by a board of trustees spasmodically financed by the government—a three years' grant of £500 was followed by a three years' grant of £1000, and that by a three years' grant of £250 and one year's of £100. In 1905 the whole collection was taken over by the government and placed in the executive building, where an art gallery was formally opened by Lord Chelmsford on 18 December 1905. The wall-space has for many years been inadequate, and many pictures are stored; Cadogan Cowper's 'Grave Scene from *Hamlet*,' Arnesby Brown's 'The Drove,' and Charles Sims's 'Morning News' are prominent among those shown, and the sculptured head 'Esther' by Harold Parker is also noticeable.

Western Australia.—In 1895 the Perth Museum was enlarged, and the opportunity was taken to display a small collection of pictures. In 1901 the Duke of York (now King George V) laid the foundation-stone of an art gallery, but the building was not proceeded with until 1906, and the gallery was opened by the governor of the State on 25 June 1908. The pictures, though comparatively few, are carefully selected, and include works by Gainsborough, Lawrence, Clausen, and Daubigny, and the Australians Heysen, McCubbin, and Phillips Fox.

Tasmania.—The Hobart art gallery is housed in a room in the Tasmanian Museum, and is managed as part of the museum. Poynter's 'Chloe' and several works by the Tasmanian artist Piguenit are its principal possessions. In another room is shown a collection of paintings illustrating Tasmanian history and ethnology. The Royal Society of Tasmania also owns a collection of historical paintings and drawings, which include a series of pencil drawings by Conrad Martens.

In several States there are small country galleries. Ballarat, Bendigo and Castlemaine in Victoria, Tamworth in New South Wales, and Launceston in Tasmania have the best-known. Each has a small collection of pictures as a permanent nucleus, but depends for its maintained

interest on pictures lent by the central State galleries.

Arthur, Sir George (1784-1854), born at Plymouth on 21 June 1784, joined in 1804 the 91st (Argyllshire) Highlanders (ensign, 1804; lieutenant, 1805; captain, 1808; major, 1812; colonel on the staff, 1814; colonel, 1837; major-general on the staff, 1837; major-general, 1846; lieutenant-general, 1854). He served in Sir James Craig's expedition to Italy in 1806, was afterwards adjutant of the light battalion on service in Egypt, and was engaged in the attack on Rosetta; in 1808 he served under Sir James Kempt in Sicily, and in the following year commanded the light company of his regiment in the expedition to Walcheren, where he took part in the attack on Flushing. For his services he was thanked in general orders, was appointed deputy-assistant-adjutant-general on the field, received the freedom of the city of London and a sword, and was similarly honoured by his native town. He afterwards served as military secretary to Sir George Don, governor of Jersey, and in 1812 was made assistant-quartermaster-general in Jamaica. From 1814 to 1822 he was lieutenant-governor of British Honduras, where he studied problems arising out of slavery and the proposed emancipation measures. Returning to England on leave in 1822 to give the British government the benefit of his advice, he was chosen to inaugurate reforms in the system of transportation to Australia, and in 1823 appointed lieutenant-governor of Tasmania, with powers that practically made him independent of his nominal superior at Sydney (see *H.R.A.* I. xi. 109). 'His strong good sense and humanity' writes Sir. A. Arbuthnot in the *Dictionary of National Biography,* 'indicated the possibility of a middle course between the extreme severity of the system which would make transportation simply deterrent, and the over-indulgence of the system which aimed at reforming the convict by gentle treatment. He held that it was possible to make transportation a punishment much dreaded by criminals, whilst offering every facility for reform to those who were not hardened in crime, but he entertained no quixotic expectations of frequent reformation.' He reached Hobart on 12 May 1824. Just before his arrival John Lewes Pedder (q.v.) had been appointed chief justice of the island, and had on 7 May proclaimed a new charter of justice; and the act that created a supreme court also provided for the separation of Tasmania from New South Wales. Accordingly Colonel Darling, on his way from England to assume the government of New South Wales, visited Hobart and on 3 December 1825 formally proclaimed Tasmania a separate colony. Arthur was compelled to bring into existence executive and legislative councils; but he refused to be hampered by them. Strong in the knowledge of his high aims and greater experience, he altered or annulled laws which stood in his way, suspended officials who would not work harmoniously with him, and fought the British government itself when it sent out orders that he thought ill-advised. Despotic as his rule was—possibly just because it was despotic, and his—the colony grew and prospered. During his 12 years the population trebled, the revenue increased sixfold, and trade grew from £75,000 a year to £900,000. Education and religion prospered equally; the bush-ranging evil was mastered and almost exterminated; the convict population was classified, and its most dangerous elements segregated on Tasman's Peninsula, whence escape was almost impossible; the few aborigines, who had been driven into an attitude of bitter hostility to the whites, were gradually collected and similarly segregated on the islands north-east of Tasmania. But in carrying out these reforms—for reforms they were, if not exactly the reforms that the humanitarian spirit of the time demanded—Arthur's masterfulness brought him repeatedly into conflict with the local and the Sydney press, which was struggling for freedom. He had, it is true, the unswerving support of the best of the Tasmanian pressmen, James Ross; but the criticism (often deliberately malign) of less worthy opponents has lived longer than Ross's eulogies; and in this as in other respects Arthur, with noble aims and exceptional ability, was fighting the spirit of the age.

Four events of his lieutenant-governorship are specially notable, and are narrated in detail elsewhere: the creation of the Port Arthur convict settlement (see Convicts), the creation of the Van Diemen's Land Company (q.v.), the Black War (see Tasmania), and the expeditions of Batman and Fawkner, which resulted in the foundation of the Port Phillip settlement (see Victoria). After 12 years of rule he returned to England in March 1837, and received the Hanoverian Order. At the end of the same year he was sent as lieutenant-governor to Upper Canada. Here he ruled during a dangerous period: an abortive rebellion was barely over when he arrived, and one of his first tasks was to meet and crush invading bands from the United States. When in 1841 the two Canadian provinces were united under a single governor, Arthur received a baronetcy for his services, and in 1842 became governor of Bombay. His work in India was even more arduous than that previously demanded of him, and was excellently done. Throughout the Afghan and Scinde wars, the cross-currents of Lord Ellenborough's viceroyship, and the ever-recurring quarrels of Outram and Napier, Arthur kept a clear head and a steady course, winning and retaining the respect of all those otherwise discordant personalities as well as of the Company's directors. Moreover, in his own province he initiated reforms in irrigation, land-taxation and sanitation, besides pioneering the construction of railways and the reclamation of the Bombay foreshores. Returning to England in 1846, he was made a privy councillor. He died in London on 19 September 1854.

Arthur's abilities and character cannot be gauged solely on his Tasmanian achievements. Like Macquarie and Gipps—both great men, who made bitter enemies and suffered for it—he was set to administer an Australian colony at a time of transition, and earned deep unpopularity by enforcing his policy (which he had been specially chosen to enforce) against the wishes and interests of influential local residents. Tasmania for him, as for the British government of his day, was intended for the safe imprisonment and eventual reform of convicts, not for the settlement of free men, and it is obvious that in a prison or a reformatory the free man and his free institutions are intruders. Further, he found the colony infested with bushrangers, whose cruelties had turned the aboriginal inhabitants into bitter enemies of every white man. The bushrangers he exterminated, partly by hunting down those already abroad, partly by cutting off the supply at its

source—Macquarie Harbour and the worst of the assigned convicts. When it became clear that this action had come too late to restore friendly relations with the blackfellows, he took the only course that seemed still open, that of segregating them. In these ways he came into conflict not only with the self-seeking aims of influential colonists, but also with the new philanthropics of the era—which sought to extend the rule of a revivifying kindness over convict and blackfellow alike. And the philanthropists, noble-souled but occasionally intolerant of actual facts, have had most to do with telling Arthur's story; nor have they always extended their kindness to him. He had faults, no doubt, and made mistakes, some of them grave. But the moral of them is not that he was a monster or a tyrant: it is, rather, that the British transportation system could not be satisfactorily administered even by a man of his calibre. Against the mistakes he made in Tasmania we must set the fine achievement of his later governorships, which would have been crowned, but for his failing health, with the governor-generalship of India itself. Unselfish, of inviolable integrity, a pre-eminently able administrator, George Arthur stands out among our governors and among Britain's great public servants. (K.H., 1837; Bart., 1841; P.C., 1847.)

Asbestos. This substance has been discovered in all the States except Victoria, but rarely in payable quantities. In New South Wales it has been found to occur near Barraba in the north and Gundagai in the south; the average annual yield for 1920-22 was 723 tons. In Queensland a belt of country between Cawarral and Canoona (south-west of Rockhampton) shows seams, the fibre from which has been found, despite a certain lack of tensile strength, suitable for the manufacture of fibro-cement, sheeting and tiles; but no payable deposit has been located. In South Australia, deposits of the 'mountain leather' and 'mountain cork' varieties have been found at Oollawirra (north-east of Petersburg) and of the blue variety near Eudunda (west of the Murray bend), and Hawker (south-east of Lake Torrens). In Western Australia the fibrous chrysolite variety has been found south-east of Cossack, in the district between the head-waters of the Yule and the Nullagine; the average annual yield for 1920-22 was 191 tons. In 1899 Tasmania produced 200 tons; no more was raised until in 1916 her chief deposit was located at Anderson's Creek in the Beaconsfield goldfield (west of the Tamar); this in 1918 yielded 2854 tons, valued at over £5000, but latterly the yield has fallen off. The average quantity produced annually in Australia in 1920-22 was 916 tons.

Asclepiadaceae, a large family (chiefly tropical or subtropical) of herbs, trees or twiners, usually exuding a milky juice. Fifteen genera, comprising 68 species, are indigenous. The leaves are entire; flowers in small clusters. The genus *Marsdenia* has 15 species, chiefly climbers. *M. Leichhardtiana* is the 'carcula' of the aborigines of central Australia; they eat (either raw or roasted) the milky unripe fruits, which are about the size of an acorn. *Sarcostemma australe* (the Caustic Vine of Queensland) is a leafless climber with fleshy stems, the leaves being replaced by minute scales. It is suspected of being poisonous to stock. Its milky juice has been used as a healing application to wounds.

Ash, a name popularly applied to several indigenous trees outside the genus *Fraxinus,* which is not represented in Australia. For Brush Ash see RUTACEAE; for Crow Ash, URTICACEAE; for Elderberry Ash, ARALIACEAE; for Prickly Ash, ORITES; and for Red Ash, RHAMNACEAE.

Ashton, JULIAN ROSSI, born at Penzance in Cornwall in 1851, and at the age of 13 placed in the civil engineering branch of the Great Western Railway, employed his spare time in study at the West London school of art (a branch of South Kensington) and, having accumulated savings from work done for *Cassell's Magazine* and other periodicals, in 1871 went to Paris and joined the newly-established Académie Julien. After a second period of work in London, during which he had several small paintings in the Royal Academy exhibitions, he migrated in 1878 to Melbourne to work for the *Illustrated Australian News* and the *Australasian Sketcher.* In 1883 he came to Sydney, and for the next three years toured Australia making sketches for the *Picturesque Atlas of Australia;* then he settled in Sydney, and became a prominent figure in the art world there. In January 1889 Henry Parkes made him a trustee of the national art gallery of New South Wales, and he forthwith used his influence to have Streeton's 'Still Glides the Stream' bought for the gallery, thus recognizing the value of that artist's work six years before the Melbourne gallery did. He was president of the Art Society of New South Wales from 1886 to 1892, and of the Society of Artists in 1897-8 and (after its resuscitation) in 1907-21. In 1899 he resigned his trusteeship of the gallery in order to gain fuller independence as a critic of contemporary art, but maintained his personal influence on the artistic life of the community: it was mainly through his efforts that (*a*) a scholarship of £150 a year was awarded in 1900 to George Lambert (q.v.) to pursue his art studies in Europe, (*b*) £250 was spent by the New South Wales government in 1902 on procuring a permanent artistic record of certain older streets of Sydney which had never been modernized, (*c*) the now undoubted if bizarre genius of Norman Lindsay was given its chance in 1907 as Streeton's had been in 1890. Of Ashton's own work the outstanding examples are his portrait of Henry Parkes (1890) in the Sydney gallery (a replica is in the federal parliament house at Melbourne) and those of Henry Gullett and Archbishop Kelly. W.M.

Assignment System, a form of service under which convicts were allotted as servants. The first free settlers, who arrived in New South Wales early in 1793, received small grants of land, under a condition (among others) that 'the service of convicts should be assigned to them free of expense, such convicts to have two years' rations and one year's clothing.' Phillip at first suggested that this privilege should be limited to the first fifteen settlers; subsequently, however, the system developed into one under which the services of convicts might be obtained by anyone who could feed and clothe them, and by 1804 was so fully taken advantage of that the governor could not get enough to carry out indispensable public works. By Darling's time assignment to persons living in Sydney had become a scandal, as it gave the convict practically the privileges of a free man after working hours; moreover, the wives of convicts had been coming out as free settlers and ar-

ranging that their husbands should be assigned to them. In 1827, therefore, the system was restricted to up-country assignments, and assigned convicts and their wives were forbidden to keep shops or engage in any form of salesmanship. In 1837 Bourke was ordered to consider the probable effects of a cessation of the system; from 1 January 1839 it was severely restricted, and in 1841 was abolished altogether. See CONVICTS.

Astelia, a small genus of the family Liliaceae, extending to New Zealand, the southern extremity of South America, and the Antarctic, includes chiefly alpine herbs that frequently grow in bogs, occasionally (especially in the New Zealand species) epiphytal, densely tufted, and clothed more or less thickly with long silky hairs. The leaves have bases sheathing the stem; fruit a globular berry. The pyramidal sprays of unisexual flowers are shorter than the leaves, loosely branched in the male and densely packed in the female clusters. *A. alpina* is the only indigenous species.

Asthma Herb. See EUPHORBIA.

Astroloma, a genus of the family Epacridaceae, endemic in Australia, and found chiefly in western areas. The succulent drupes of several species are edible, and are known in New South Wales as 'ground berries,' in Tasmania as 'native cranberries;' they have a viscid, sweetish pulp. *A. pinifolium* is a low, diffuse plant, densely covered with cylindrical leaves like pine-needles. The flowers are reddish, shading to yellow.

Astronomy. The record of astronomical observations made on Australian soil during the 50 years after the landing of Captain Cook consists almost entirely of the determination of geographical positions by navigators and explorers distinguished in early Australian history. Governor King, however, records that Baudin in 1802 'prolonged his stay to observe the transit of Mercury,' which took place on 9 November.

The longitude of Fort Macquarie (Sydney) is one of the astronomical results of this period to which much interest and importance have been attached—perhaps because for many years afterwards this point was adopted as the origin of Australian longitudes. In 1788, shortly after the arrival of the 'first fleet,' a small observatory was erected on Dawes Point under the direction of Lieutenant Dawes of the marines, who had been sent by the British board of longitude to make astronomical observations. The first building was of wood, but was soon replaced by a substantial stone structure. This may be regarded as the first observatory established in Australia solely in the interests of astronomy. In 1791 it was equipped with a transit instrument sent out by the British astronomer-royal. The building still exists, but is not used for astronomical purposes.

Matthew Flinders, among his numerous and important geographical observations, determined the latitude and longitude of Dawes Point, the latter with an error (as shown by the latest computations) of 2 seconds only. In 1821 Sir Thomas Brisbane, failing to obtain the support of the British government, erected and equipped at his own cost an observatory at Parramatta. Among the instruments he provided were a transit instrument (by Troughton) of 3¾ inches aperture and 64 inches focal length, a mural circle (also by Troughton) 2 feet in diameter with telescope of the same length, a 16-inch repeating circle (Reichenbach), a 46-inch achromatic telescope (Banks), clocks, chronometers, and other minor appliances. The four instruments first mentioned are still in the Sydney observatory: H. C. Russell called them 'large but essentially faulty.' For use during the solar eclipse of September 1922, the repeating circle was, however, cleaned and transformed into a modern portable almucantar with a self-registering transit micrometer.

Brisbane had already engaged two assistants —Carl Rümker (q.v.) and James Dunlop (q.v.). His main object was to determine the position of stars (down to the eighth magnitude) between his zenith and the south pole. Observations were begun on 2 May 1822, and were continued by himself and his assistants until 16 June 1823; then Rümker left the observatory, but stayed on in Sydney. Brisbane finding himself over-occupied with public affairs, Dunlop worked for the most part by himself until 2 March 1826. Four years later the records were placed in the hands of William Richardson of the Greenwich (England) observatory, who constructed from them the well-known Parramatta Catalogue of 7385 stars for the equinox of 1825; this was published in 1835. The frontispiece of this work is a sketch and ground-plan of the Parramatta observatory. When Brisbane returned to England at the end of 1825, he left his instruments behind at the request of the legislative council: they were subsequently purchased by the colonial government at his own valuation. In March 1826 Dunlop left the observatory. But the work there now became of more immediate public importance, the Royal Society (of London) having proposed to the British government that an arc of the meridian should be measured in New South Wales; and Darling's executive council in July 1826 appointed Rümker to take charge of the observatory, with orders to proceed immediately with this admeasurement. On 21 December 1827 Rümker became the official astronomer of the first government observatory in Australia. He left the country in 1828 on leave, but while away threw up his appointment and became director of the Hamburg observatory. For three years after his departure the observatory remained inoperative; but in 1831 Dunlop was made superintendent, work was resumed in 1832, and continued under him for 16 years. On his retirement in 1847 the observatory, which had become much dilapidated, was closed and dismantled, the instruments being stored.

The results of Rümker's work (published in the *Transactions* of the Royal Society of London (1829), and the *Memoirs* of the Royal Astronomical Society of London, vol. iii) include the rediscovery of Encke's comet at its first predicted return on 2 June 1822, the discovery of a new comet (1824 I) on 15 July 1824, and many observations for latitude and longitude. Between 1826 and 1828 Dunlop at his own house in Parramatta was observing nebulae, clusters, and double stars, with a reflecting telescope of 9-inch aperture, constructed by himself; a catalogue of 629 southern nebulae and clusters and a catalogue of 253 southern double stars were published in the *Transactions* of the Royal Society of London (1828) and in the *Memoirs* of the Royal Astronomical Society, vol. iii. Dunlop continued his determinations of star-positions from 1831 to 1847; his records are contained in eight manuscript books now

at the Sydney observatory. On 30 September 1833 Dunlop, now back at the government observatory, discovered a comet, and on 13 March 1834 independently discovered another which had first been seen by Gambart at Marseilles 12 days before. In 1880, when the building which had once been the Parramatta observatory was fast disappearing, the colonial government erected a marble obelisk on the spot formerly occupied by the transit instrument.

Sydney observatory was built on the recommendation of Sir William Denison. Dunlop had recommended a site on the heights of North Shore, but Flagstaff Hill was selected on account of its great convenience for giving accurate local time to ships in the harbour by means of a time-ball signal. The first equipment consisted of the Parramatta instruments, which, but for the appeals of Phillip Parker King, would have been taken back to England and sold by the British authorities. The first director was W. Scott who had been selected for the post by the astronomer-royal, Sir George Airy; he arrived in Sydney on 1 November 1856, but was not able to begin regular observations until June 1858, when the observatory building was completed. The instruments were in poor order, and when Donati's comet appeared (in October 1858) it was found that the colony's astronomer had nothing but a sextant wherewith to observe it. To remedy the defect a Merz achromatic telescope, equatorially mounted (7½ inches aperture and 124 inches focal length), was purchased by the government and installed in 1861—just in time to observe the great comet of that year.

Scott resigned on 30 September 1862. John Tebbutt (q.v.) having refused the position, George Roberts Smalley was selected by Sir George Airy, and reached Sydney on 7 January 1864. Henry C. Russell (q.v.), who had been Scott's assistant since 1859, had charge of the observatory in the interval. In the period 1862-1870—the meridian instrument being very imperfect, and no other obtainable—the work of the observatory was limited to routine observations of 'clock' stars (for time), observations of the moon and moon-culminating stars (for longitude), and occasional observations of comets. Smalley devoted the greater part of his time to terrestrial magnetism, meteorology, and the initiation of a trigonometrical survey of the colony (see GEODESY).

The directorate of H. C. Russell, which began in 1870, inaugurated an era of reform and progress. A large achromatic equatorial telescope by Schroeder, with a fine object-glass (11¾ inches aperture, 12½ feet focal length), was erected in 1874; three years later a new transit circle by Troughton & Simms (6 inches aperture, 85 inches focal length) was added to the observatory equipment. With these new instruments a programme of work, comprising determination of star-positions and observations of double-stars, was carried on for many years, the result being published in three separate volumes —*Astronomical Results* for 1877-78 and 1879-1881, and *Double-Star Results*, 1871-1881. The *Memoirs* of the R.A.S., vol. 50 contain double-star results for 1882-1889. Other double-star results for subsequent years have been published in various lists in the *Astronomische Nachrichten* (Nos. 3154, 3240, 3303, 3369, 3423).

Work on the Sydney astrographic zones (see later on in this article), and meridian observations of reference stars in those zones, have practically absorbed the whole of the astronomical activities of the Sydney observatory since 1892. Russell retired in 1904; Alfred Henry Lenehan, who had been chief assistant for many years, filled the position till his death in 1908; then W. E. Raimond had charge of the observatory for four years, and in August 1912 W. E. Cooke (formerly director of the Perth observatory, Western Australia), was appointed government astronomer of New South Wales, and professor of astronomy at the university of Sydney. Under his directorship the astrograph has been much improved, and the international work (which had been languishing) has been reorganized and is vigorously prosecuted. Transit observations have been remodelled in accordance with the recommendations of the 1909 international congress, and publication of the catalogues connected with the astrographic scheme has been commenced.

Williamstown observatory.—In 1853 R. J. L. Ellery was appointed by the government of the colony of Victoria to establish a small observatory at Williamstown, chiefly in order to supply accurate time to shipmasters in Hobson's Bay. A time-ball apparatus had already been installed for the purpose, on a tower at Point Gellibrand; the first time-signal was issued in August 1853, observations being made at first with a sextant. In 1854 a 25-inch transit instrument and a good astronomical clock were obtained from England, and in 1866 a more ambitious transit instrument by Troughton & Simms (aperture 3½ inches, focal length 45 inches) was installed. In 1858 a geodetic survey of the colony was decided upon, and placed in charge of the astronomer. The observatory having by this time acquired considerable importance, a board of visitors was appointed by the governor-in-council on 30 January 1860, to report to the government upon the work of the observatory and make recommendations for its efficiency. In 1861 observations were commenced with a new Troughton & Simms transit circle (object-glass of 5 inches aperture, 72 inches focal length), with a circle 4 feet in diameter, divided to every 5 minutes and read by 4 microscopes. A Troughton & Simms achromatic telescope (4½ inches aperture, 5 feet focal length) equatorially mounted, and other instruments, including an Airy zenith sector and a chronograph, were obtained about the same time. In 1863, the site at Williamstown having become unsuitable for astronomical observations, the observatory was removed to the Domain park (four miles north-east from Williamstown, and 1½ miles south-east from the centre of Melbourne) where a new building had been erected for it.

The work of the Williamstown observatory is published as *Astronomical Observations*, 1861-3. It contains a catalogue of 546 stars, a series of right ascensions and north polar distances of the moon—upon which the longitude of the observatory was then based—and a series of observations of Mars and comparison stars at its opposition of 1862.

Melbourne observatory (i.e. that in the Domain park) was ready to commence work at the end of June 1863, when it absorbed the magnetic and meteorological observatory on Flagstaff Hill (at the west end of Melbourne) whose founder and director, George Neumayer, had decided to return to Europe. Ellery took charge of the new observatory. For the first few years astronomical observations were limited to the requirements of the geodetic survey of the colony; but in 1866 the observatory took up a share of the observations for a southern *dürch-*

musterung, proposed by the Royal Astronomical Society of London, which was to be carried out on the same scale as Argelander's *dürchmusterung* for the northern hemisphere. The zone allotted to Melbourne was included between 60° and 80° of south declination. The results of this work, which continued for six years, comprise the mean places, for the equinox of 1875, of 48,672 stars down to the 9th order of magnitude; but these have never been published. Grubb's 4-foot Cassegrain reflector was installed in 1868. The optical dimensions of this instrument are as follows: aperture of primary mirror 4 feet, focal length 360 inches; aperture of secondary mirror 8 inches, focal length 74.7 inches; equivalent focal length of the combination, 1994 inches. The mirrors, of which there is a spare set, are of speculum metal. For about 20 years it was employed mainly in the systematic revision of southern nebulae discovered by Sir John Herschel at the Cape of Good Hope. The first instalment of an account of these observations is given in *Southern Nebulae*, Part 1, issued by the observatory in 1893. In 1874 a photoheliograph by Dallmeyer was acquired for the transit of Venus of that year. It has an aperture of 4 inches, and 60 inches equivalent focal length, and can be adjusted to give good photographic images of the sun from 4 inches to 8 inches in diameter. For many years this instrument took daily photographs of the sun. In the same year two new equatorial telescopes were installed; one by Cooke & Sons of York with an achromatic object-glass (4½ inches aperture, 60 inches focal length), the other by Troughton & Simms (8 inches aperture, 110 inches focal length). The latter telescope was permanently mounted in a separate building erected for it on the observatory grounds, and has since (and throughout) been used for observing comets and double and variable stars, and for micrometric measurements. Spectroscopic observations of the sun and of some 300 southern stars were also made with it.

But meridian observations, for time and determinations of star-positions, always formed the most important part of the routine work of the Melbourne observatory; they were made with the 5-inch transit circle from 1861 to 1883, and the results were published in *Melbourne Observations*, vol. i, and in two star-catalogues. In 1884 a larger transit circle (by Troughton & Simms) was installed, and since then all meridian work has been done with it. This instrument is of dimensions and design similar to those constructed for the observatories of Cambridge (England) and Harvard. Its object-glass has 8 inches clear aperture and 108 inches focal length. Its two circles are 3 feet in diameter. The first results of observations made with this instrument are contained in the third *Melbourne Star Catalogue*, for the equinox of 1890, which has been published; two other catalogues, for epochs 1900 and 1910, which contain all the reference stars of the Melbourne astrographic zones, have been prepared but have not yet been published.

Ellery retired in June 1895, and was succeeded by P. Baracchi, who resigned his position in August 1915. Dr. J. M. Baldwin is the present director.

Adelaide observatory.—In 1855 Charles Todd (afterwards Sir Charles) was appointed superintendent of telegraphs and astronomical observer for South Australia. It was not till 1874, however, that a suitable observatory and some astronomical equipment were provided for him by the South Australian government. The instruments comprised, at first, an equatorial telescope with achromatic object-glass (8 inches aperture, 10 feet focal length), and the 3½-inch transit instrument originally used at the Williamstown observatory. This had been lent to Todd in 1867 by the Victorian government for use in determining the position of the 141st meridian, which is the boundary between Victoria and South Australia; Todd employed it to observe clock-stars in the vicinity of that meridian, and afterwards installed it in the Adelaide observatory, where until 1880 it was used for the determination of local time. Besides this, a time-ball apparatus was fitted on a tower at the Semaphore, 9 miles away; the first signal was issued on 2 August 1875. In 1880 the observatory was provided with a transit circle by Troughton and Simms (6 inches aperture, 85 inches focal length) provided with two circles of 30 inches diameter. The observations which have been made with this instrument, in addition to the ordinary clock-star observations, relate mainly to special investigations of latitude and reflection, and include an extended series of stars in Weisse's catalogue in the belt between 0° and 4°, south declination. Most of the work done with the 8-inch equatorial telescope consists of observations of the surface details of the planet Jupiter, the phenomena of Jupiter's satellites, and comets. The present programme is (*a*) time determinations, (*b*) observations of reference stars of the Sydney astrographic zones, (*c*) field latitudes and longitudes, (*d*) variable and double stars, (*e*) miscellaneous observations.

Sir Charles Todd retired in 1906, and was succeeded by R. F. Griffiths, who resigned in 1908 to join the newly-created federal weather bureau. Since 1909 G. F. Dodwell has held the position.

Perth observatory originated in 1896 as a branch of the colonial secretary's department, W. E. Cooke being appointed director. It is situated on Mount Eliza, a sandhill 200 feet above sea-level, overlooking the city of Perth. The equipment consisted of an 8-inch reflecting telescope intended for use with a coelostat, another reflecting telescope of 12 inches aperture, a transit circle by Troughton & Simms (6 inches aperture, 71 inches focal length) provided with two divided circles of 30 inches diameter, a standard twin astrographic telescope by Grubb, two machines for the measurement of astrographic plates similar to those in use at Oxford and Greenwich, clocks, chronometers, etc. The first few years were devoted chiefly to instrumental investigations and observations for latitude and longitude and routine meridian observations for time. After 1900 the activities of this observatory were almost entirely absorbed by astrographic work and collateral determinations of the places of reference stars, which work was completed and published recently. In 1912 Cooke resigned his position to take up duties at Sydney. Since then H. B. Curlewis has been in charge.

Brisbane observatory.—In 1879 the Queensland government purchased the outfit of a private observatory owned by the late Captain O'Reilly, and removed it to a site on Wickham Terrace. It comprised only a small transit instrument, a chronograph, two clocks, and two chronometers. In 1921 it was temporarily removed to the Insurance Building in George-street (lat. 27° 28′ 23.00″ S., long. 10h. 12m. 6.48

sec. E.) as the earlier position was rendered unsuitable by the erection of private buildings adjacent to it and on the meridian of the transit instrument.

The astronomical work, which has been carried on by officers of the survey department under the direction of the various surveyors-general, has been confined to meridian transit observations for time for public purposes, and for the determination of the longitudes of many places whose positions were required for the compilation of maps. A sidereal clock and chronograph are employed for recording electrically times of transit and receiving time-signals from distant stations. Time-signals are also transmitted to public and other institutions.

Hobart observatory.—In 1840 Sir James Ross (then engaged on his antarctic expedition) established at Hobart a magnetic station and astronomical observatory equipped with a transit instrument, altazimuth and clocks. The building was near government house, and was in charge of Lieutenant Kay, R.N., Sir John Franklin (then governor) assisting with the magnetic observations. Observations were continued until 1854. In 1882 Captain Shortt was appointed government meteorologist, and established an observatory at the military barracks, providing it with a transit instrument, a small equatorial and two clocks; this observatory issued a time-ball signal daily at 1 p.m. until 1911, since when the signal has been supplied directly by the Melbourne observatory.

Mount Stromlo observatory.—In 1910 a committee was appointed by the Commonwealth government to select a suitable site within the Federal Territory for the erection of a temporary observatory to house a Grubb equatorial reflecting telescope (9 inches aperture, 135 inches focal length) which had been presented to the Commonwealth by James Oddie of Ballarat. The selected site was Mount Stromlo, about seven miles from the centre of Canberra. A substantial structure of concrete was built, supporting a revolving dome 18 feet in diameter, under which the telescope was mounted on a solid masonry pier. During 1912 and 1913 a series of observations—visual, telescopic and spectroscopic—was made, including the examination of close double stars, details of planetary surfaces, and solar prominences; and long-exposure photographs of selected regions of the heavens were obtained with a 6-inch Voightlander portrait-lens attached to the telescope. Baracchi reported that Mount Stromlo was decidedly suitable for the projected observatory; the temporary observatory was then closed, and the establishment of a permanent observatory had to be postponed owing to the outbreak of war. In 1922-3, however, the matter was again mooted, and on 1 January 1924 Professor W. G. Duffield, D.Sc., was appointed director. Dr. Duffield (who is a South Australian, trained at the universities of Adelaide and Cambridge, and was in 1909 appointed professor of physics at the university of Reading) has secured two valuable gift telescopes, one of which, presented by J. H. Reynolds of Birmingham, is a reflector exactly similar to that at the Helwan observatory in Egypt, and will be the most powerful instrument in Australia except the Cassegrain reflector at Melbourne. Its mirror is 2½ feet in diameter. The second telescope, a six-inch refractor, was presented by James Oddie. The Stromlo observatory will have attached to it two assistants and a research fellow.

Non-official Astronomers.—John Tebbutt (q.v.) began to make astronomical observations in 1854, and continued them in his private observatory at Windsor, New South Wales, for 60 years. Francis Abbott in 1855 erected a small observatory at Hobart, where for some years he made systematic observations for local time, as well as observations of comets and variable stars, with a Cooke achromatic equatorial telescope of 3½ inches aperture. In 1862 he added to his outfit a better transit instrument by Dallmeyer, an achromatic equatorial telescope by the same maker (4½ inches aperture, 5 feet focal length), and, shortly afterwards, a larger equatorial by Dollond (7 feet focal length). He specialized in comets—'1865 I' was discovered by him one day before Moesta saw it at Santiago—and in observations of the variable star Eta Argus. T. O. Smeaton and F. G. Singleton at Adelaide observed the 1874 transit of Venus with achromatic telescopes of 3½ and 3 inches aperture, and A. W. Dobbie with an 8½-inch reflector. Dobbie, who was an observing member of the Mars section of the British Astronomical Association, constructed his own reflectors, and in 1905 completed one of 18 inches aperture. W. J. MacDonnell was already in 1871 making systematic observations at Port Macquarie with a Grubb achromatic telescope of 6 inches aperture. Later he removed to Sydney, where he continued astronomical work with a smaller equatorial by Parker (4½ inches aperture). He was one of the official party who at Eden, New South Wales, observed the transit of Venus of 1874, and one of the observers of the Jupiter section of the British Astronomical Association, in whose *Journal* and *Memoirs* most of his work was published. G. D. Hirst, well known for his remarkable skill in planetary drawings, is one of the prominent observers of the Mars and Jupiter sections of the British Astronomical Association. His principal instrument is an achromatic telescope (4½ inches aperture) by Cooke & Son. His work, which extends over 40 years, comprises studies of the details of planetary surfaces and observations of comets and double stars.

Between 1880 and 1890 several amateur makers of reflecting telescopes were at work, including R. W. Wigmore and R. Shafer of Melbourne, M. Watt, M. Corbett, M. F. Madsen and Walter Gale of Sydney. Among the observers of this period A. B. Biggs used an 8½-inch reflecting telescope and a 3½-inch achromatic telescope; his observations were chiefly on comets. Dr. Bone mounted in 1882 at his private observatory at Castlemaine (Victoria) a fine equatorial telescope by Grubb (object-glass of 8 inches aperture), but he died shortly after, and his telescope was purchased in 1887 by John Tebbutt. In 1887 a private observatory, Mount Pleasant, was established by James Oddie at Ballarat. The principal instruments were a reflecting telescope (26 inches aperture) and another Newtonian reflector (12 inches aperture); the mirrors for both telescopes were made by Captain Baker, whom Oddie had placed in charge of the observatory. Other Victorian observers of note are David Ross, who discovered two comets ('1883 II' and '1906 II') and T. E. Davidson, who discovered the comet '1889 IV.'

Walter Frederick Gale, one of the most skilful observers in New South Wales, commenced to make his own reflecting telescopes in 1882, while still a student. In 1892 he made observations of Mars with an 8½-inch reflector by With, and his four drawings of the planet were repro-

duced in the *Memoirs* of the British Astronomical Association. He is said to have been the first to note the delicate markings, now known as 'oases,' recorded also by Pickering, and later by Lowell, Flammarion and Antoniadi. The *Memoirs* contain the results of Gale's numerous observations of Jupiter and its satellites. He has independently discovered six comets, two of which bear his name—Gale 1894 II, and Gale 1912 I; Sawerthal (1888 I) was seen by Gale independently only one day after Sawerthal discovered it at the Cape of Good Hope; the other three proved to be the returns of Fabry 1886 I, Winnecke 1892 IV and Tempel[2] 1894. He has also discovered several double stars and a ring nebula.

In the nineties R. T. A. Innes, now director of the Natal observatory, and J. C. Merfield, now chief assistant at the Melbourne observatory, were conspicuous. Innes, with a 6½-inch equatorial refractor and a Newtonian reflector with mirror 16 inches in diameter, made systematic observations of variable stars and double stars. Merfield for many years made observations of comets and coloured stars, and was at one time director of the 'coloured stars' observing section of the British Astronomical Association. His instruments were an equatorial refractor (6¼ inches aperture) by Cooke & Son, and a reflecting telescope, with mirror 7 inches in diameter. He had also a small transit instrument. He contributed to astronomical periodicals numerous important papers dealing with the definitive elements of comet orbits, perturbations, and other problems of gravitational astronomy.

Branches of the British Astronomical Association were formed in Sydney in 1894 and in Melbourne in 1897. The Melbourne branch, after a few years of struggle on the part of its few enthusiastic promoters, languished and was dissolved in 1905. The Sydney branch was vigorous, and soon formed special observing sections for comets, planets, coloured stars, sun, and meteors. Some of the observers in these sections have been noted above. Among others who have, by observations or writings, increased astronomical knowledge are Sir George Knibbs (q.v.) who succeeded John Tebbutt as second president of the branch; Thomas Roseby, a fluent writer on astronomical subjects, who was twice president; H. F. Marsden, who wrote a valuable paper on the construction of a reflector of 18 inches aperture; T. M. Close, who computed comets' orbits and lunar occultations by graphical methods, and prepared astronomical data for observers (as did also Innes and Merfield); and Hugh Wright, ex-president of the branch and member of the observing sections Mars and Jupiter, who with a Newtonian reflector (8½ inches aperture) by Browning has made many observations on coloured stars, double stars, nebulae, solar spots, meteors, planets, and comets. The Astronomical Society of South Australia originated in 1892 as a branch of the Royal Society of that State. It is intimately connected with the Adelaide observatory, and the work of its members is published in the transactions of the society.

Astrophotography.—The Paris Astrophotographic Congress of 1887 resolved on the production of an international catalogue and chart of the heavens, the work of which was to be shared among 16 observatories scattered about the world. H. C. Russell, who was present from Australia, was authorized by the governments of New South Wales and Victoria to nominate the Sydney and Melbourne observatories as two of the 16. To Sydney was assigned the region between 57° and 64° declination south; Melbourne took that between 65° south and the south pole. In 1900 the Perth observatory came into the scheme, and was given the region between 31° and 41° south declination, originally assigned to the Rio de Janeiro observatory. Special instruments (twin telescopes, usually known as astrographs) of a form and dimensions prescribed by the congress, were installed at Sydney and Melbourne. The latter, by Grubb, reached Melbourne in 1891, and was mounted in a special building erected for it in the observatory grounds. The Sydney astrograph (except the Steinheil object-glass) was made in Sydney under Russell's personal supervision; while he was waiting for the object-glass, he mounted on the instrument a Dallmeyer star-camera (6 inches aperture, 32 inches focal length) and took a series of long-exposure photographs of the Milky Way. An album published in 1890 contained 17 of these, with descriptions.

Astronomical Expeditions.—On six occasions Australian expeditions have been organized for the observation of astronomical phenomena:—

1. Total eclipse of the sun, 11 December 1871. An expedition to Eclipse Island in northern Australia was organized and conducted by Ellery and Russell, as directors of the Melbourne and Sydney observatories. The weather was unfavourable, and the results unsatisfactory.

2. Transit of Venus, December 1874. Four separate parties were organized by Russell and placed at Eden, Goulburn, Woodford (on the Blue Mountains) and Sydney. Tebbutt observed the transit at Windsor. Ellery sent out three parties, to Mornington, View Hill (near Bendigo), and Glenrowan, and observed the transit himself at Melbourne. In South Australia it was observed by Todd and Singleton at the Adelaide observatory, and by Smeaton and Dobbie at their homes in the suburbs. Although at several stations cloudy weather interfered with the observations, yet on the whole results were good, and formed an important part of the investigation of the solar parallax based on the general results obtained from this transit.

3. Transit of Venus, 7 December 1882. Russell sent out five parties, to Port Macquarie, Clarence River, Dromedary, Katoomba, and Lord Howe Island: all were unsuccessful, owing to bad weather. Tebbutt at Windsor and Russell himself at Sydney were similarly disappointed. From Victoria Ellery sent a party to Hobart in Tasmania, locating another at Sale in Gippsland. The Sale party failed through bad weather; the Hobart party, and Ellery himself at Melbourne, did well. Todd observed the transit successfully at Wentworth on the Murray.

4. Total eclipse of the sun, 10 May 1890. An expedition to Bruni Island in Tasmania was organized by Baracchi under the auspices of the Australasian Association for the Advancement of Science, but nothing was seen of the eclipse, owing to cloud and rain.

5. Total eclipse of the sun, 29 April 1911. This was observed with fair success at Vavau (an island of the Tonga group) by an expedition organized by the Australasian Association aforesaid, conducted by Baracchi, and subsidized by the Commonwealth government.

6. Total eclipse of the sun, 21 September 1922. This eclipse was expected to give excellent opportunities for testing the validity of Einstein's theory of relativity; and, as the line of totality crossed Australia from east to west, expeditions from British and American observatories were organized to conduct observations at

several stations in the Commonwealth, besides those sent out by Australian observatories. The most favourable view-point, meteorologically as well as astronomically, was at Wallal (Wollal) on the Ninety-mile Beach, about half-way between Broome and Roebourne in Western Australia. Here foregathered five parties — the Crocker eclipse expedition from the Lick Observatory in California (which included the government astronomer of New Zealand), the Toronto University expedition, an Indian party from the Kodackanal observatory at Madras, a private party from England, and the official expedition from the Perth (W.A.) observatory under Charles Nossiter. The Adelaide observatory sent a party to Cordillo Downs in the far north-eastern corner of South Australia. The other expeditions stationed themselves along the southern border of Queensland—those from the university of Sydney and the Sydney and Melbourne observatories at Goondiwindi, one from the New South Wales branch of the British Astronomical Association at Stanthorpe on the inter-State railway line, and an observer from the terrestrial magnetism department of the Carnegie Institute of Washington, U.S.A., at Coongoola, a little north of Cunnamulla. The weather conditions during totality were excellent at all these stations, and valuable observations were made and photographs taken, those secured at Wallal being of course the most important both from the suitability of the station and the prominence of the observers. When the results could be co-ordinated, it was announced by some authorities that Einstein's theories had been decisively confirmed; but later discussions of them leave this statement still unproven.

P. B.

Atalantia. See EREMOCITRUS.

Atalaya, a genus of the family Sapindaceae, endemic in Australia except for one species. There are five indigenous species, chiefly eastern; they are trees or shrubs, with large leaves divided into leaflets, small flowers in sprays, and winged fruits. *A. hemiglauca*, best-known as Western White-wood (the 'boorbal' of the aborigines), is a small tree of 30-40 feet, well represented on the western plains, where it is ranked as one of our best fodder-trees. It is easily propagated from seeds, and should be largely planted in arid districts. It has a scaly, friable bark, and a white or pale yellow fissile timber. It exudes a useful pale-coloured gum.

Atkins, RICHARD (1745-1820), born in England in 1745, was the fifth son of Sir George Bowyer, but took the name Atkins under the provisions of a will. He entered the army, but little is known of his career there, except that in 1783 he was adjutant of the Isle of Man militia. After retirement he came to New South Wales with Grose, reaching Sydney on 14 February 1792, and was almost immediately selected by Phillip to be registrar of the vice admiralty court. When John Macarthur resigned his position as inspector of public works in February 1806 Hunter put Atkins into his place; and the personal enmity which characterized the relations of the two men burst into a flame that did not die down while Atkins lived. Atkins wrote abusive letters to Macarthur, which he afterwards showed to successive governors. Macarthur made grave accusations against Atkins in a letter to Lord Portland, then colonial secretary; tried to prosecute him criminally for libel when in 1796 Hunter (under orders from the colonial office) made him acting judge-advocate during the absence of Collins in England; and later based on a charge of his unfitness for his position the proceedings which ended in the 'Bligh rebellion.' Atkins acted as judge-advocate until in 1798 Richard Dore came out with a commission from England, was made deputy judge-advocate when Dore died in 1800, and in 1802 attained the full position—chiefly, it would seem, because no more suitable person was available; King was not content with his modicum of legal knowledge, and Bligh had a very poor opinion of him. He also held the posts of magistrate (since 1792), registrar of imports and exports (1799), and commandant of the Loyal Association at Parramatta (1800) and Sydney (1806).

In January 1808 Macarthur, who had been a thorn in the side of every governor and had quarrelled particularly with Bligh, was summoned to stand his trial for 'deceiptfully, wickedly and maliciously contriving and abetting against William Bligh Esquire.' Atkins, as judge-advocate, was president of the court; but Macarthur protested against him as biassed, malicious and a liar (the epithets are but a feeble summary of the actual words used), and the other six members of the court, all officers of the New South Wales Corps, backed Macarthur, who had been their fellow-officer. It is a sidelight on the character of Bligh that he there and then provoked the famous 'rebellion' by his unhesitating support of an official whom less than three months before he had described to the colonial office as weak, a blabber, a drunkard, ridiculous and in legal matters 'subservient to private inclination.' The remainder of this story will be found under BLIGH, WILLIAM.

It need only be said here that Atkins, suspended from his office by Johnston, was reinstated (very unwillingly) by Foveaux, presided —as by law he was bound to do—at the trial of George Suttor the loyalist, and was in the end replaced on Macquarie's arrival by Ellis Bent. Macquarie sent him to England as one of Bligh's witnesses in H.M.S. *Hindostan*; he gave evidence at the court martial on Johnston, and then retired into obscurity. He died in London on 21 November 1820.

Atkinsonia, a genus of the family Loranthaceae, has one endemic species, *A. ligustrina*, found within a limited area of the Blue Mountains. It is an erect bush of 2-3 feet, terrestrial but root-parasitic; flowers numerous, in short axillary spikes with 6-8 varicoloured petals, dark-reddish to buff; leaves alternate, 1-1½ inches long; fruit ovoid, scarlet, 3-4 lines long, and highly ornamental.

Atrichornis. See SCRUB BIRD.

Australia, Discovery of, and Early Voyages to.

Portuguese and Spanish period.—After the discovery of the New World in 1492 the Spaniards still kept up their attempts to reach by the westward route lands and islands of the far East, which they believed to contain strange civilizations and enormous wealth. Cipango, with its golden palaces and untold treasures; Cathay, extolled by Marco Polo; the marvellous spice-bearing islands—these were the objects of their search, as they had been of that voyage of Columbus which accidentally and unavoidably brought him to the American continent. The

Portuguese, meanwhile, voyaging in the opposite direction, rounded the Cape of Good Hope, reached first India, then Malacca and Java, and by 1526 had followed the chain of the East Indian Archipelago to New Guinea. These two nations by a series of bargains proceeded to divide the new world between them. A grant made by Pope Alexander VI in 1493, slightly modified by the Treaty of Tordesillas next year, drew the line that separated their possessions 370 leagues W. of the Cape Verde Islands (about 50° W., according to the maps of those days): when Spanish ships pushed westward from the American coast across the Pacific, and Spanish explorers began to claim rights of discovery in the Spice Islands, they claimed an extension of this line into the Pacific which would have given the Moluccas and New Guinea to Spain. In 1529, however, an arrangement was reached which pushed the Pacific line 297 leagues east of the Moluccas, thus giving that group entirely to Portugal, while Spain was compensated by letting her retain the Philippines, although they were really within the Portuguese sphere.

Portugal happened to be concerned chiefly with trade, and devoted most of her energies to exploitation, rather than exploration, when once she had fastened her grip on the coast of India and on the Spice Islands. Geographers have always been at a loss to account for the late discovery of the Australian continent, and many —from Alexander Dalrymple to George Collingridge—have toyed with the notion that certain old maps (notably the 'Dauphin' map of 1530 and one made by Jean Rotz in 1542) indicate the discovery of a large part of the Australian coast by the Portuguese before 1542. Those who wish to follow up this scent will find a full and well-documented discussion in Wood's *Discovery of Australia*, pp. 82-129. Apart from these improbabilities, the only important discovery made by a Portuguese (for his own nation) in waters that can be called Australasian was that of the northern coast of New Guinea by Jorge de Menezes in 1524-6; and this was the accidental result of currents, and of his ignorance, rather than his adventurousness. The Spaniards, on the other hand,

were explorers by nature, and in addition were keen to reach new 'spice islands' not yet annexed by Portugal; it is with their expeditions that the exploration of Australasian waters really commences.

The circumnavigation of the world by Magellan's famous ship *Vittoria* (1519-21) during which Magellan was killed in the Philippines, included the traversing of Australian seas from Timor towards the Antarctic, but put no Australian territory on the map. It was followed up, as promptly as was possible in those days, by a series of expeditions from Old and from New Spain. In 1525 Loaysa led several ships from Corunna in Old Spain to occupy the Spice Islands; but storms beset him at both ends of Magellan Straits, and only one vessel reached the goal. Another—a mere pinnace—managed to make the Mexican coast and report to Cortes, who sent his kinsman Alvaro de Saavedra to search for the rest of the expedition. Saavedra reached the Spice Islands in a little over two months, picked up the survivors, took in a cargo of spices, and started back by a route heading south-east, so as to avoid the north-east trades. Consequently he found himself coasting for no less than 250 leagues along the northern shores of an island which he called Isla del Oro; but his description of the natives as woolly-haired and African-looking seems to have induced another explorer (de Retez) 20 years later to rename the island 'New Guinea.' Neither that year nor again at all did Saavedra return to New Spain

Cortes in 1536 sent out Hernando de Grijalva, who sailed from Acapulco to the Isla del Oro, and was murdered by his own crew near Geelvink Bay. But the magic word 'gold' was ever an alluring bait; in 1543 the small *San Juan*, in an unsuccessful attempt to reach New Spain from the Philippines, attached the name of its captain to Cape della Torre just west of the Sepik River; and two years later Ortiz de Retez in the same vessel coasted along New Guinea for 650 leagues and named the principal features he noticed on a plan which almost amounts to a log of the voyage. Striking New Guinea at the Gabo de Deses (now the Cape of Good Hope), he entered on his chart the names 'S. Thiago' (Saint James, whose day is May 1), 'St. Andres' (Saint Andrew, June 23), 'Y. S. Paulo' and 'R. de S. Petro' (SS. Peter and Paul, June 29), 'R. de S. Augustin' (Aug. 28)—now called the Sepik River—and finally 'Ancon de la Natividad de Nuestra Sinora' (Nativity of the Virgin Mary, Sep. 8) now called Cape King William. At this point he left the New Guinea coast, and the islands now known as New Britain and New Ireland are marked, though not named, on his chart.

The next attempt was made from South America. On St. Isabel's day, 19 November 1567, Sarmiento and Mendana sailed from Callao to discover what lay south of the New Guinea coast. Sarmiento wished to steer WSW. across the ocean spaces; but Mendana's fear of the unknown dragged him always northwards, and in February 1568 the expedition found itself off a large island not far from the position laid down for New Guinea. Sarmiento, who was in charge of affairs relating to discoveries, landed, formally annexed the island under the name of Santa Ysabel (the natives, it appears, called it Atoglu), and named his landing-place Baya de la Estrella (Bay of the Star)—a name which has been recently restored to it. Making a long stay in the group, he discovered the islands now called Guadalcanal, Malaita, Florida, Savo, and San Cristobal, and—in view of the riches he hoped to find when more thorough search was possible—called the whole group Islas de Salomon. In September he was back in Callao, excited about his find; but the Spanish authorities, both in Spain and in America, were busy with more immediate needs, and nothing further was done for many years.

From the year 1580, however, a new era of Pacific exploration begins. The unwieldy empire of Spain was being harassed by the English and the Dutch, both at home and on the sea; while the English mariners set themselves to hunt for gold and silver (mainly by the simple expedient of seizing Spanish treasure ships), the Dutch obeyed their commercial instinct and fastened on the ports and islands previously exploited by Portugal, which in 1580 became a province of Spain. Drake in 1579-80 and Cavendish in 1587-8 voyaged through the Pacific, raided in the Malaysian islands, and made their way home by Java and the Cape of Good Hope. Houtman in 1595 took a long-planned expedition round that Cape to Bantam in Java, and within the next seven years 70 Dutch vessels had used the same route. It was obviously time for Spain to wake up, if she wished to retain territory in these eastern waters. Mendana had never quite given up hope of being allowed to revisit the Solomons; in 1595 he was at last let go. Settlement rather than discovery was the object. Three large vessels and a frigate conveyed the expedition, which included the wives of many of the explorers—notably Mendana's wife, Ysabel de Barreto, and Mariana de Castro, wife of Lope de Vega. The chief navigating officer of the expedition was Pedro Fernandez de Quiros (Queiroz, Quir). Leaving Callao on 9 April 1595, with orders to plant a colony in San Cristobal and from that base to explore the surrounding ocean in search of the supposed southern continent, Mendana discovered the Marquesas and on 7 September sighted a new island, which he called Santa Cruz. (This name is now applied to the whole group, Mendana's island being known as Nitendi.) On the 21st the colony was formally proclaimed; but native hostility, coupled with sickness and mutiny among his crew, broke Mendana's spirit. He died there; his widow, with Quiros to help her, brought the remnant of the expedition safely to the Philippines; but Lope de Vega (who must not be confused with the great Spanish writer, Lope Felix de Vega Carpio) and his followers, who had left the main body before it reached Santa Cruz, were never heard of again.

Quiros, however, evidently considered himself in the succession, and took up the work with enthusiasm. He went back to Spain to report to Philip, then to Rome to interest the Pope in missionary work among the newly found tribes. (More than a century later a petition of Melanesian islanders for more missionaries and better administration bases its plaints on the work and promises of 'the good Pedro Fernandez de Quiros, in whose grave our hopes too were buried.') Possibly on this account, more probably because Dutch and English encroachments in the Spanish seas were increasing, Quiros was sent off again from Callao to plant a fresh colony on Nitendi and then go in quest of the 'Continent towards the south.' With two ships and a brigantine, Luis Vaez de Torres (Luiz and Luys, Vaes and Baez, are variants often met with) being second in command, he sailed from Callao in December 1605; but before reaching Nitendi he sighted Taumaco in the Duff group (18 April), and the natives there were so positive about extensive land areas to southwards that he made straight south past Tucopia (21 April) and soon saw in front of him what looked like a great barrier of land—'the eye could not turn to any point that was not all land.' On 1 May 1606 he entered what he described as a great bay, which 'contains twenty leagues of shore, and is surrounded by a large population . . . . The port of Vera Cruz is so capacious that it would contain at anchor a thousand ships.' Seven islands off the port 'subtend two hundred leagues. One of them, about twelve leagues distant, is fifty leagues in circumference.' The land Quiros called 'Austrialia del Espiritu Santo,' the bay 'The Great Bay of Saints Philip and James,' and the port 'Vera Cruz;' and possession was taken of the territory on 10 May (Whitsunday) with the utmost possible religious ceremony. After a month's stay in this spot the expedition sailed southwards (8 June) to discover the extent of the land in that direction; but head winds and mistaken orders now split the fleet in two. Quiros, making back, but told by his pilot that it was impossible to reach the bay and anchor, steered for a pre-arranged rendezvous at Santa Cruz, failed in that also, and in the end returned to Acapulco (3 October). Torres—who gives quite a different account of the separation, with a Spanish noble's sneer at the commoner Quiros

—anchored in the bay, stayed there another fortnight, sailed far enough round the island to prove that it was merely an island, and then made off southwards to pursue the search for the still undiscovered southern continent. He missed it by very little. According to his own account (contained in a letter found 156 years later in Manila) he reached 21° S. lat. not far from the Queensland coast; not sighting land, he turned northwards, found himself tangled up in the islands off the eastern end of New Guinea, worked up into the bight of the Gulf of Papua, and came down again as far as 11° S. lat.—which must have brought him within sight of Cape York and given him a passage through Endeavour Strait. But Torres, it must be remembered, was a Spanish noble not personally interested in exploration and mainly anxious to obey exactly (and to show that he had so obeyed) his king's orders; his letter consists of vague expressions in which are imbedded extracts from his pilot's observations, not always correctly understood by the commander himself; between Espiritu Santo and the Moluccas he does not mention a single name except 'New Guinea,' not even the names which we know from Spanish charts were given by his expedition to certain ports it discovered and explored. Consequently his own account must be checked carefully with charts, whereupon its inaccuracy becomes evident, and the following statement of his journeyings (for which the entire credit is due to Captain F. J. Bayldon, R.N.R., of Sydney) may be taken as authentic:—

Steering south-west from Espiritu Santo to a point about 360 miles north-east of Keppel Bay (Queensland), Torres then turned north-west towards the eastern end of New Guinea as marked on his chart, but found himself unable to round Cape Sudest. He therefore made west along the New Guinea coast, and on his way entered at least three harbours which can be definitely identified—Jenkins Bay (which he discovered on 18 July, as we learn from Spanish charts of the time), Orangerie Bay (10 August), and Triton Bay (18 October). Between Orangerie and Triton Bays he coasted New Guinea to the head of the Gulf of Papua, then skirted a great shoal south-westwards, looking for a passage through it, and through an opening probably just south of Saibai (though some authorities think he went as far south as Banks Island) reached the Arafura Sea. Working back to the New Guinea coast, he passed westwards to Cape False, then north to Cape Steenboom, and so to Triton Bay.

At several points he took formal possession of the land for Spain. But he had no desire to find out any more than was laid down in his orders; 'I doubt' he wrote, 'if in ten years could be examined the coasts of all the islands we descried;' and his long, slow voyage along coral-reefs and mud shoals only increased his longing to be back in the Moluccas as quickly as possible. His adventurous but unlucky voyage ended at Manila in the Philippines—and even then such discoveries as he had made remained unknown. In accordance with the policy of withholding useful information from dangerous competitors, which most nations in those days practised, his diaries were until late in the eighteenth century hidden away in a monastery at Manila, and Torres Straits had to be rediscovered by Captain Cook.

This Quiros-Torres exploration has been described in some detail, because it has of late years given rise to several paradoxical suggestions. One, originated by the late Lawrence Hargrave, was that the truant Lope de Vega reached Port Jackson (where he is supposed to have left rude carvings of himself and family on the rocks), coasted the Australian shores thence northwards to Port Curtis, and was wrecked there. All this story is built up on a few almost obliterated scratches on the rocks of Rose Bay in Port Jackson, and an unconfirmed legend about a Spanish wreck on Facing Island. A second suggestion is that the land discovered by Quiros really was Australia—the chosen spot being, curiously enough, again Port Curtis. This is based mainly on the exaggerations of Quiros himself, who in ten memorials (written in five years) enlarged grandiloquently on the extent and riches of his beloved 'Austrialia.' It is certain that Santo—the island which, according to the best obtainable evidence, he did discover—does not answer to his perfervid description, but this may be excused in an explorer anxious for another job; and all the rest of the evidence—the map drawn by Diego de Prado, the statements of Torres, the latitude given by Quiros himself—supports Santo, and Santo only.

Dutch and English period.—The expedition of Quiros and Torres closes the period of Spanish activity. Quiros set sail again a few years later, still in search of the Great Australian Continent; but he died at Panama on his way out, and by the abandonment of his expedition the Dutch were allowed to remain sole masters of the situation.

It would seem that they did not wish to waste time; for, strange to say, their first claim of Australian discovery coincides almost exactly in point of time with Torres's advent. The locality, also, is that of Torres's unconscious discoveries. In March 1606 (a few months, therefore, before the arrival of Torres) the Dutch yacht *Duyfken* sailed right into the big bay that came to be known in after years as the Gulf of Carpentaria. This voyage of the *Duyfken* (Little Dove) has been so much challenged of late years that it is necessary to go into it in some detail. The account given in the instructions issued to Tasman for his voyage of 1644 (see below) is that 'the unknown south and west coasts of Nova Guinea were discovered over a length of 220 miles, from 5° to 13¾° S. lat.,' that some of the sailors were killed by blackfellows, and that the captain (Willem Jansz) gave the name of Cape Keerweer to 'the extreme point of the discovered land in 13¾ degrees S. lat.' It is this name that seems to have caused all the difficulty. Long after Tasman's time no Cape Keerweer could be found on any chart of the Gulf of Carpentaria: the only cape of that name was shown on the coast of New Guinea in lat. 7° S. The name shown on modern charts, on the western side of the Cape York Peninsula, was put there by Flinders on the authority of the Tasman instructions. Moreover, in an earlier set of instructions issued to Tasman for his 1642-3 voyage, Cape Keerweer is said to lie in 18° S. lat., so that its exact position must have been at least doubtful. But 'keerweer' merely means 'turn back,' and may be found again and again on old Dutch charts, to indicate the point at which some exploring vessel began its return voyage; it is the equivalent of Cook's Cape Turnagain on the eastern coast of New Zealand, and might well occur in 7°, 13¾°, and 18° S. lat. as a result of three Dutch voyages south-eastwards, just as it did on the Celebes coast after a north-eastward exploration. Mistakes about a name like that do not in-

validate the record of an otherwise well-attested voyage.

The earlier evidence for this consists of (*a*) notes in the journal of a certain Captain Saris in 1605-6, mentioning the departure and return of 'a small pinnasse of the Flemmings' sent to make discoveries in New Guinea: (*b*) a series of references to the *Duyfken* by name, in a journal kept by Captain Carstensz of the *Pera* on his voyage through the same waters in 1623-4. These references are frequent and detailed. One of the rivers visited, for instance, is described as the river 'which the men of the *Duyfken* went up in 1606, and where one of them was killed by the arrows of the blacks.' Other manuscripts connected with the Carstensz voyage show that they had charts of the coast along which they were travelling: and these charts could only be those drawn from the *Duyfken's* information. Those who challenge the authenticity of this voyage support their incredulity by alleging that it would be impossible to sail across so wide a gap as Torres Straits without getting some hint that it was a through passage and not merely a bight. But the early discoverers—Jansz of the *Duyfken* and Carstensz—were not, in fact, convinced that it was merely a bight. Carstensz's journal and the 1644 Instructions show clearly that the existence of a strait was suspected: Tasman, for instance, was specially directed to anchor for several days in a certain bay (actually in Endeavour Strait), and make careful search there for a passage to the South Sea, while Carstensz records day by day the events which prevented him from pushing eastwards anywhere in the Torres Straits area. His track can be almost exactly marked on modern charts, and his failure satisfactorily accounted for. Moreover, the failure to recognize the existence of great gulfs, and the tendency to draw lines across their mouth on the chart to signify a coast-line, was common in those days; all early Dutch charts, for instance, show Celebes as a solid island by marking a coast-line straight across from Banka Strait to Greyhound Strait. Finally, the supposed discovery that New Guinea was solidly connected with Australia is definitely claimed by Tasman's second-in-command. On a copy of his chart now in the British Museum there is an inscription (translated, of course, as the copy is an English one), 'This large land of New Guinea was first discovered to join ye South Land by ye Yot Lemmen' — that is, by one of Tasman's 1644 vessels. And the claim could not have been made if any earlier explorers had considered the question definitely settled. There is no reason, therefore, to question the *Duyfken's* voyage. The contemporary account of it is lost, just as is the account of Tasman's 1644 voyage, which is only known to us by a line drawn on a chart. Jansz's voyage was merely an imperfect precursor of the *Pera's*—and we know all about that.

In January 1623, Jan Carstensz or Carstenszoon was sent with the ships *Pera* and *Arnhem* (or *Aernem*) to follow up the tracks of the *Duyfken*. His journal is preserved almost complete, and we can follow his wanderings very accurately. At first he worked along the southern coast of New Guinea, passing False Cape and reaching a point east of the present Anglo-Dutch boundary, and was thankful to escape from the dangerous coastal shoals west again into open sea; he called the shallow area 'Drooge Bocht'—Dry Bight—and turned south with the object of running down to 16° S. lat. before making for home again. On the morning of 12 April he sighted the Australian coast somewhere about 11° S.; on the 15th he attempted a landing in about 15° S., but failed; two days later, however, he landed and went some way inland, capturing a blackfellow (whom he brought back to Batavia) and having several skirmishes with the aggrieved tribe. The discovery of 'great quantities of human bones' convinced him that the blacks were cannibals. On the 24th, in (according to his calculations) 17° 8′ S. lat., he found himself off the swamp-lined estuary of the Gilbert River (he named it Staten Revier), and could get no fresh water; his seaman's instinct warned him that he was approaching the bottom of a bight, with on-shore winds; and it was decided to return. Almost immediately the *Arnhem* deserted, making directly back towards the Aru Islands and discovering on the way that part of the Northern Territory which has since been called Arnhem Land. Carstensz kept steadily up the coast, charting and naming its principal features, rarely discovering fresh water, seeing few blacks but many fires; after a landing in 15° 20′ S. lat. or thereabouts he gave vent to his feelings —'we have not seen one fruit-bearing tree, nor anything that man could make use of; there are no mountains or even hills . . . . this is the most arid and barren region that could be found anywhere on the earth; the inhabitants, too, are the most wretched and poorest creatures that I have ever seen.' However he did get 'plenty of delicious fish' and, a little later, 'excellent vegetables or pot-herbs.' Again and again he landed and attempted to open up communications with the natives, but found them more and more hostile as he went north. At last he anchored well inside the mouth of Endeavour Strait, was blocked by easterly winds from following the coast-line farther, entangled himself in the shallows under Prince of Wales Island, and again escaped westwards with a sigh of fervent thanksgiving. On 15 May he left Australian waters and made back to Amboyna, which he reached safely on 8 June after one of the most thorough and persevering voyages of exploration recorded to the credit of Dutch seamanship. He has been dealt with here over-minutely, perhaps; but the usual accounts of his work are so inadequate and distorted that it seems worth while to do him justice. The results of his voyage were twofold. His account of the country dissuaded the Dutch authorities from any further attempt to exploit those regions; but his account of the Drooge Bocht, both on its northern and on its southern sides, revived their hopes of finding a waterway there into the South Seas—and if Tasman had had one-tenth of Carstensz's pluck or perseverance, Cook's work would have been done 130 years earlier.

The early Dutch cartographical period begins in the year 1627, H. Gerritsz's chart of that date being the earliest known engraved representation of the western coast-line. According to this chart the discoveries made by the Dutch along those shores, in chronological order, are as follows:

1616. Dirck Hartog, commanding the *Eendracht* (Concord), entered Shark Bay on 25 October and examined the coast between 26° 30′ and 23° S. lat. On the northern extremity of Dirk Hartog's Island (Cape Inscription) he set up a post, with a tin or pewter plate on which he recorded his visit.

1618. On 11 May the *Seewolff* sighted land in the neighbourhood of 21° 15′ S.

During July Lenaert Jacobsz in the *Mauritius*, driven out of his proper course, sighted land in 21° 45′ S., and on July 31 landed on an island whose northern point was in 22° S. This cannot be identified; but the Willems River (named after the supercargo Willem Jansz), which was set down on a rough chart recording the discovery, is supposed to be the Ashburton.

1619. On 19 July Frederik Houtman in the *Dordrecht*, one of 11 vessels voyaging together from Holland, sighted land in 32° 20′ S. but was unable to make a landing. Ten days later he came upon 'a level broken country with reefs all round it'—really the rocky islets and outlying reefs which Gerritsz for some reason named 'Houtman's Abrolhos.' The term (which means 'Look out!') is of Portuguese origin; but mariners are polyglot in their way, and the mere use of a Portuguese phrase on a map cannot be strained to carry the weight that some historians wish to place on it. In one of the vessels of Houtman's fleet, the *Amsterdam*, Jacob Dedel was the supercargo, and after him they named the coast between Shark Bay and Champion Bay.

1622. In March the *Leeuwin* (Lioness) rounded the SW. corner of the continent, where a cape now bears her name, and examined the shore as far as King George's Sound. Next year came the voyage of Carstensz already narrated.

On the 16th or 26th of January 1627 (for accounts differ), the *Gulden Zeepaert* (Golden Sea-horse), skipper Francois Thysz or Thyssen—having on board Pieter Nuyts, afterwards ambassador to the court of Japan, and subsequently governor of Formosa—sighted the south coast near Cape Leeuwin, and made a close examination of the coast-line for 1000 miles, as far as Nuyts Reef and cluster of islets. The skipper's Christian name and that of Nuyts were given to two of the largest islands of the group, 'I. St. Pieter' and 'I. St. Francoys,' and the whole coast was named Nuytsland. This and the next discovery were 'accidental,' say the Tasman Instructions. In 1628 the *Vyanen*, homeward-bound from India, came upon the NW. coast in 21° (about the Kimberley district), and coasted along about 50 leagues without gaining any particular knowledge, 'only observing a foul and barren shore, green fields and very wild black barbarous inhabitants;' on board was a man—possibly the commander—named Gerrit Frederikszoon De Witt, which accounts for the 'G. F. De Wittland' found on Dutch charts.

In 1628 an expedition of 11 vessels was equipped in Holland for the East Indies; three of them sailed on 28 October before the others, under the command of Commodore Francis Pelsart. The *Batavia*, Pelsart's ship, was driven out of her course during a severe storm, and separated from the other two; she lost her reckoning, and on the night of 4 June 1629 struck on one of the islands of Houtman's Abrolhos, becoming a total wreck. The story of what followed will be found under PELSART; the only practical result was to confirm more strongly the Dutchmen's impression that the western coast of Australia was 'barren and accursed' and its inhabitants obnoxious and unfriendly. Pelsart in his journal mentions a Jacob Remessens River about 22° 17′ S., where none exists; this may, of course, have been a vague memory of the Willems or Ashburton.

The next Dutch discoveries were of minor importance. Gerrit Thomasz Pool with the yachts *Amsterdam* and *Wesel* was sent out from Banda in 1636 to make a detailed exploration of the Gulf of Carpentaria—which, it was still surmised, might yet be found to be the northern end of a passage running clear through the South Land into the southern seas. Pool coasted along New Guinea to 5° S. lat., made a landing there, and with three of his crew was murdered by the natives. The supercargo, Pieter Pieterszoon, took charge and continued the voyage; but adverse winds drove the ships due south on to the coast of Arnhem's Land, and after a long and fruitless voyage they returned to Banda.

Tasman's First Voyage.—In August 1642 Anthony Van Diemen, then governor-general of the Dutch East Indies, and his council availed themselves of the noted ability of Abel Janz (or Janszoon) Tasman to order a more extensive exploration of the South Land than had hitherto been attempted. Their main intention was to find out the extent of the continent, and to ascertain whether a passage north or south of it led into the South Sea. The *Heemskerck* and the *Zeehaen* were equipped for the voyage. Tasman commanded the expedition; the pilot-major was Franchoys Jacobszoon Visscher, and the skippers Ide Tjerksen and Gerrit Janszoon.

In October they left Mauritius and, steering SE., reached the latitude of 49° 4′ S. They then steered E. by N., with the intention of gradually working northwards to the Solomon Islands. On 24 November they made a landfall, apparently a little north of Cape Sorell in Tasmania, where the wind drove them off the land; rounding South-west Cape, they got a wind from the north and sailed along the south coast. Tasman named the outlying islands (and some peaks on the precipitous coast which he mistook for islands) after members of the council of India—De Witt, Sweers, Maatsuyker; to the basaltic rock off South Cape, whose black surface was covered with guano, he gave the name Pedra Branca, after a similar rock on the coast of China that the Portuguese had named long before; then sighting Borcel's Eylanden (the Friars), he turned north to Storm Bay, out of which a violent north-west gale drove him far to sea. On 1 December he rounded Cape Pillar (he called it De Zuyd Kap, and the neighbouring island Tasman's Eylandt—note that the varied spellings are taken from his chart), and came to anchor in North Bay near Green Island; next day Visscher was sent to explore Frederick Hendricx (Blackman's) Bay, and on the 3rd Tasman took formal possession of the country for Holland. On 4 December he started again, intending to sail northwards along the coast and discover a good watering-place; but the still prevailing north-wester kept him well offshore, and in despair—or from a constitutional dislike to venturing ashore in strange countries—he decided to stand away eastwards. After naming Marias Eylandt, Schoutens Eylandt and Vanderlins Eylandt—the last after one of the members of the council of seventeen (but it was really Freycinet Peninsula, which he mistook for an island)—he took his departure from 'a high round mountain,' St. Patrick's Head or St. Paul's Dome. Steering due east, after nine days he sighted land again on 13 December (this was the west coast of the South Island of New Zealand, south of Cook's Strait) and gave it the name of Statenlandt 'in honour of their High Mightinesses the States General.' Coasting northwards, he entered Golden Bay, where he anchored. Here the natives in their war canoes attacked one of the *Zeehaen's* boats, killed three of the crew, and mortally wounded

a fourth. Tasman accordingly named it Moordenaars (Murderers') Bay. The ships then sailed north along the west coast, and sighted and named, on the eve of the Epiphany, T'Eylandt Drie Coninghen (Three Kings Island) and Cabo Marya Van Diemens, after the wife of the governor-general; but no landing was made in New Zealand, partly owing to bad weather and the hostility of the natives, partly because (as has been hinted already) Tasman was a notorious coward. As Van Diemen wrote about his second voyage, a 'more vigilant and courageous person' might have done great things. After rounding the north of Statenlandt they steered north-east, and on 21 January came to several islands, to which they gave the names of Amsterdam, Middleburg, and Rotterdam—now known as Tongatabu, Eua, and Anamuka, part of the Tonga or Friendly group. Tasman, who was hospitably received by the natives, weighed anchor on 1 February, discovered a few more islands, steered N. by W. to 5° or 6° S. and then W. to New Guinea, sailed along the north coast of that island, and reached Batavia on 15 June 1643 after an absence of ten months.

Tasman's Second Voyage.—During his first voyage Tasman had not even sighted the continent, nor had he brought back news of the discovery of gold or silver or rich trade for the Company, as Van Diemen had hoped; but he had circumnavigated the Great South Land, and demonstrated that it did not reach to the south pole. Shortly afterwards another expedition was equipped to make an examination of the South Land itself. On 13 January 1644, by resolution of the governor-general in council, the ships *Limmen* and *Zeemeeuw*, with the tender *Bracq*, were commissioned for the voyage. They carried a complement of 111 hands, and were provisioned for eight months. Of this voyage nothing is known except its track as shown by a line on a chart; but Van Diemen's instructions to Tasman are distinctly interesting. He was still hopeful of the discovery of gold and silver mines, but had another goal also—the opening up of trade with Chile, coupled with possible raids on the Spanish settlements in Peru—the attainment of which depended mainly on the discovery of a passage eastwards between Australia and New Guinea. The instructions were therefore particularly full and detailed. After a long preface, in which previous voyages between 1606 and 1636 were enumerated and briefly described, Tasman was ordered to leave Banda on the last day of February, coast New Guinea to the Drooge Bocht, and spend two or three days there looking for a passage to the Pacific. If none could be found, he must follow the *Pera's* track southwards in the hope of finding a passage that way to the just-discovered Van Diemen's Land. If that hope too proved false, he must follow the coast westwards to Eendracht Land. Van Diemen at that time thought that Arnhem Land was an island, behind which a short cut to Willems River could be found.

Of the actual voyage, as has been said, only a track-line on a chart survives, for Van Diemen's summary of it merely states the results. It is clear, however, that Tasman landed nowhere; 'he who makes it his business to find out what the land produces' writes Van Diemen indignantly, 'must walk over it, which these discoverers pretend to have been out of their power.' As for the Drooge Bocht, he made no attempt to enter it; his track slides across its western end. Moreover, he seems to have been proud of this lack of achievement; his own chart lays stress on the fact that New Guinea and the South Land 'form all one continent together,' and reference has already been made to the inscription on his pilot's map. Tasman had roughed out the coast-line from Cape York to the Ashburton, and that was all. Van Diemen was slightly discouraged, but proposed to go on. The authorities in Holland, however, had had enough. Exploration cost money; gold-mines were not all profit; the best Dutch gold-mine was the Indian trade. In 1645 Van Diemen died, and Dutch exploration in Australian waters came to an end. There were wrecks occasionally, and accidental discoveries; but, except for a stray attempt in 1705 to penetrate the continent past Melville Island—which led to nothing but a pious belief that 'the South land in a great measure consists of islands'—Holland abandoned the barren and unfriendly regions south of the equator, and confined herself to exploiting thoroughly the rich archipelagoes of the north. It must be noted, however, that even Tasman's definite statement did not convince all Dutchmen that New Guinea and New Holland were a single mass of land; in 1685 or later Georg Eberhard Rumpf, governor of Amboina, mentioning the Drooge Bocht, added 'where, it is surmised, New Guinea is cut off from the rest of the Southland.'

One more Dutch voyage deserves notice, not so much on account of its results as because of one incident in it. On 29 December 1696 Willem de Vlamingh in the *Geelvinck*, looking for a supposed wreck, anchored near the mouth of the Swan River off an island mainly populated by rats as big as cats—wherefore he named the island Rottenest (Rats' Nest)—and rowed about 30 miles up the Swan, scaring blackfellows and birds in his progress. Thence he coasted the continent northwards to Dirk Hartog's Island; and on it they found the plate Dirck Hartog had left there in 1616. Vlamingh took it to Batavia, and it is now in the States Museum at Amsterdam; but he replaced it with a fresh plate, on which the old inscription was recorded together with one of his own. [In August 1801 the French captain Hamelin discovered this plate and remounted it on a pole; but in 1817 another Frenchman, Freycinet, took it to Paris and sent it to the Institut de France, where it has since been lost.] Vlamingh continued his coasting until he reached the Ashburton, and thence made straight for Batavia.

Dampier.—A little before Vlamingh's voyage, and just 100 years before the arrival of Phillip, the first Englishman sighted Australia. William Dampier (q.v.), buccaneer and naturalist, is one of the most interesting Englishmen of his time; but for the purpose of this article he is merely an observer of a land hitherto unknown to his countrymen. The *Cygnet*, in which he was at the moment a common sailor, on 4 January 1688 made her landfall near Cape Borda on the north-western coast, and worked round Cape Lévêque into King Sound, where the bay in which she anchored still bears her name. For nine weeks she lay there, while her crew explored the land and canoed about Buccaneer Archipelago, and Dampier studied the aborigines: his description of them as 'the miserablest people in the world—the Hodmadods of Monomatapa, though a nasty people, yet for wealth are gentlemen to these' has long been a classic, and his unsuccessful attempt to bribe them into working with the gift of an old pair of breeches and a jacket 'that was scarce worth owning' is characteristic no less of him than of them. On 12 March the

Cygnet sailed again. But, for all his avowed contempt, Dampier felt that Australia had possibilities; and at the beginning of 1699, after three years of adventure and six of obscurity, he persuaded the British admiralty to give him command of H.M.S. *Roebuck*, with 20 months' provisions aboard her, and commission him to explore the still half-mythical New Holland. His first intention was to round Cape Horn and make for the continent's eastern side, but dislike for cold climates spoilt this excellent design; he left England on 14 January, rounded Africa, and on 2 August sighted the Australian coast near Gantheaume Bay, where to this day the actual shoreline is unsurveyed and uncertain. Running northwards he entered and named Shark's (now Shark) Bay; finding no water-supply there, he resumed his coasting until he reached the group of islets now known as Dampier's Archipelago, where the tides puzzled him a good deal. Here he began to lose confidence in Tasman's chart, which he had been using as a guide; Tasman marked a continuous coast-line, and Dampier conjectured that he had stood farther off the land than he pretended, and had merely guessed at the position of the shore. He made one more attempt at landing, this time in Roebuck Bay, where he found poor water and the same miserable natives; disgusted with the whole country, he allowed the excuse of endless shoals to push him farther offshore, and in the end made for Timor, intending to reach the eastern coast of Australia north-about. From Timor he sailed along the northern coast of New Guinea and circumnavigated (and named) New Britain. His original intention of working thence down the eastern side of Australia was abandoned, mainly because he was too tired of that country to undertake fresh explorations in a rotten vessel with a half-mutinous crew; back to Timor he went, and to Ascension (where the ship foundered), and so to England. And with his departure the South Land had rest for nearly 70 years. The Dutch, growing weaker every year, found it necessary to concentrate on their known possessions in Malaysia. The English and French, though occasionally a philosophic author would contemplate schemes of Pacific colonization, were occupied with struggles for the nearer and more profitable regions of North America and India. A few voyagers traversed the Pacific westwards. Roggeveen the Dutchman (1721) struck the Samoan group; Byron the Englishman (1764-6) skirted the Society Islands and hit the Ladrones, Wallis (1766-8) practically repeated this voyage, and a third Englishman, Carteret, (1766-9) paralleled it to the south and made New Britain; Bougainville the Frenchman (1766-9) visited Tahiti, Samoa, and New Hebrides, and Orangerie Bay in New Guinea, but was scared by the breakers on the Great Barrier Reef and passed New Guinea north-about. Sooner or later the real discovery was imminent; but it was left to James Cook.

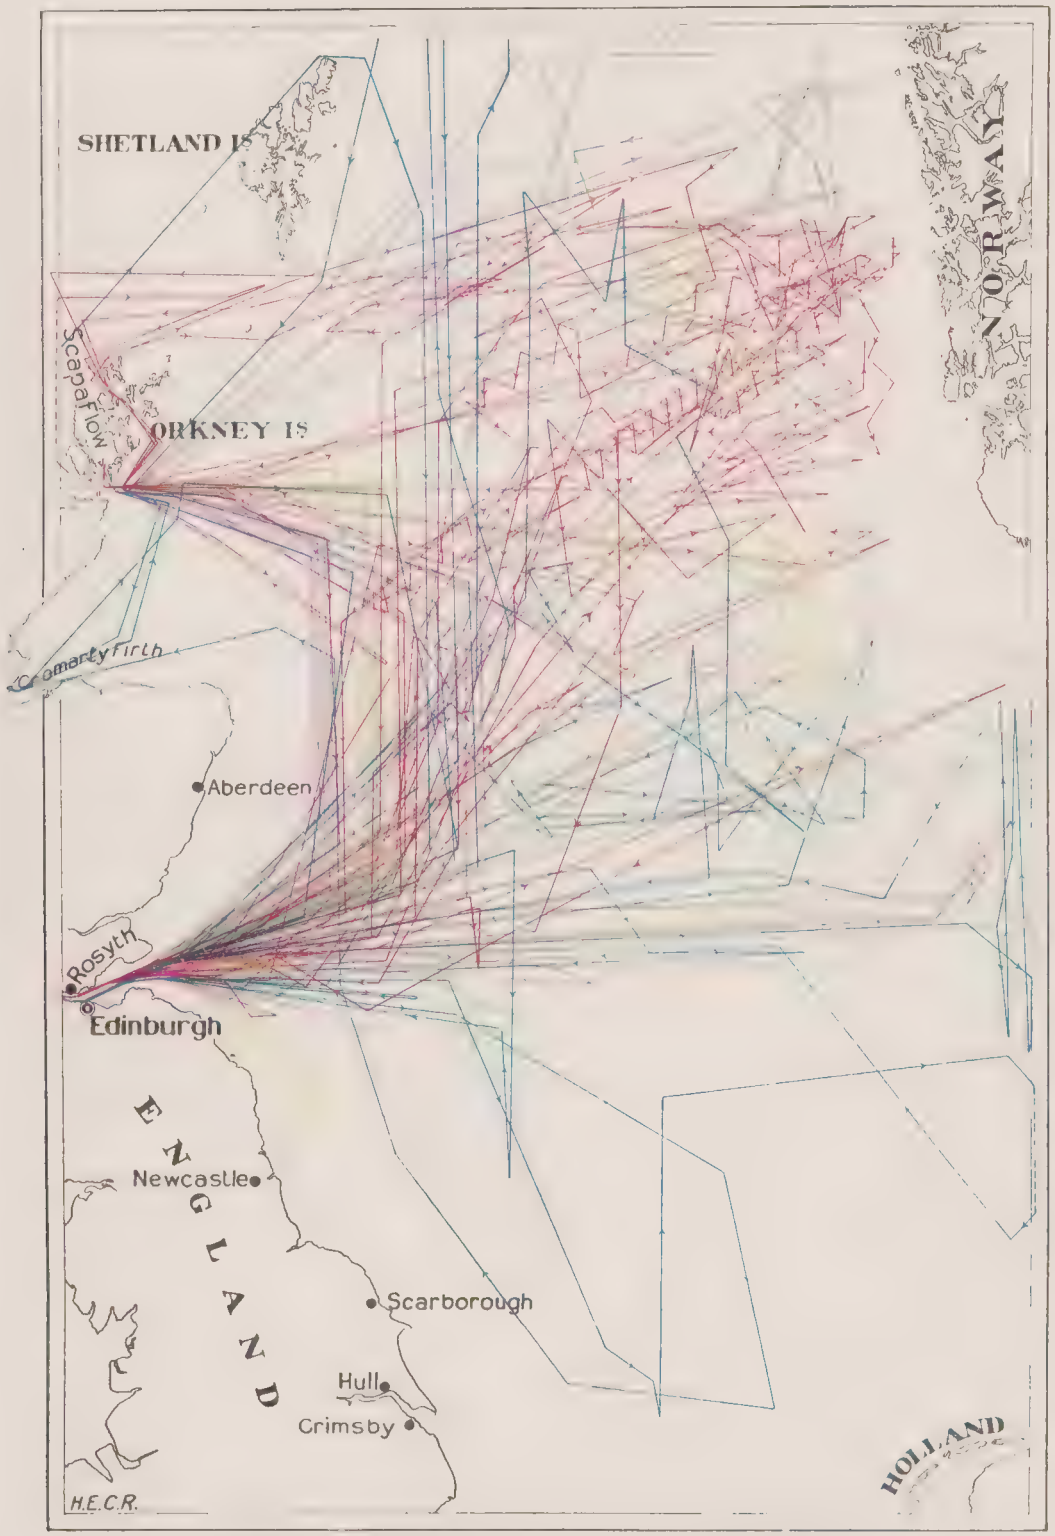
For the Spanish period the *Voyages* of Mendana, Galvano, de Morga, and Quiros, all published by the Hakluyt Society, are worth study: Markham's introduction to the Quiros volume is especially valuable. On the Dutch period J. E. Heeres's *Part Borne by the Dutch in the Discovery of Australia* and R. P. Meyjes's *De Reizen van Abel Janszoon Tasman en Franchoys Jacobszoon Visscher* are of primary importance; Walker's *Early Tasmania* and the *Voyage of Jacob Lemaire* (Hakluyt Society) should also be consulted. For Dampier, his own *New Voyage Round the World* and *Voyage to New Holland* (1729) are the only safe guides; of recent editions Masefield's (1906) is the best. On the whole period of discovery consult de Brosses's *Histoire des Navigations aux Terres Australes* (1756), Callander's *Terra Australis Cognita* (1766-8), Dalrymple's *Historical Collection of the Several Voyages and Discoveries in the South Pacific Ocean* (1770), Major's *Early Voyages to Terra Australis* (1859), and G. A. Wood's recent and excellent *Discovery of Australia* (1923). Collingridge's *Discovery of Australia* (1895) contains much useful matter, but is encumbered with improbable hypotheses.

Australia, Geography of. See GEOGRAPHY, ECONOMIC.

Australia, H.M.A.S., the first and (so far) only battleship of the Australian navy, was launched at Clydebank on 25 October 1911, commissioned in June 1913, and arrived in Australian waters in the following September. The motives and influences which caused and conditioned her building are narrated under NAVAL DEFENCE. She was intended to be one of three (or possibly four) battle-cruisers that would constitute the British battle-squadron in the Pacific, two others being maintained by Britain as flagships of the East Indies and China squadrons, and the fourth possibly in the future by Canada as flagship of a Canadian Pacific squadron. But the exigencies of European politics made it impossible for the admiralty to spare any more capital ships for Pacific waters, and when the European war broke out in August 1914 the *Australia* was the only vessel of 'Dreadnought' type flying the white ensign east of Suez.

She was a battle-cruiser of *Indefatigable* type, 19,200 tons, speed 26 knots, 44,000 horse-power; her armament consisted of eight 12-inch guns, 16 4-inch guns, and three submerged torpedo-tubes; her armour was ten inches thick on the turrets, eight inches amidships, and from three to six inches elsewhere. Excepting the Japanese, no other nation had in the Pacific any vessel to match her. Consequently, when war became imminent in July, and Admiral von Spee, the commander of the German Pacific squadron, had to decide on his first hostile acts, he put aside at once the thought of any raid in Australian waters. His two best ships, the *Scharnhorst* and the *Gneisenau*, were armoured cruisers of 11,000 tons each, armed with eight 8-inch guns, and capable of 23½ knots at best; although they could have given the big ship a great deal of trouble if attacked by her, it was obviously a futile proceeding to run them into unnecessary danger. It was for this reason (as we know from his own letters, afterwards published in Germany) that von Spee decided to leave the western Pacific altogether and make for South American waters: and thus the *Australia* by her mere presence secured the Commonwealth from raids of a most destructive kind which von Spee would certainly have made if he had had to meet light cruisers only.

Her doings during the war are narrated under NAVAL DEFENCE; but it may be repeated here that, after a period of convoy and patrol work in the Pacific (the admiralty refused—until after Coronel—Admiral Patey's repeated requests to be allowed to use her to chase the German squadron), she was taken to the North Sea and made flagship of the Second Battle-cruiser Squadron there. An unfortunate collision with her sister-ship the *New Zealand* prevented her from taking part in the battle of Jutland, but she soon resumed her station at the head of her squadron and kept it till the end of the war. What this meant in actual work at sea may be judged from the fact that, out of the 95,000 miles she covered during the war, almost 57,000 were steamed in the North Sea. In the spring of 1918 she was



NORTH SEA TRACK-CHART of H.M.A.S. *Australia*. 1915-18.
(Total distance steamed, 56,908 miles.)

used for experiments with seaplanes launched from a very short deck superimposed on one of her turrets. On 21 November of that year—the day of the surrender of the German High Seas fleet—she led the larboard line of battle accompanying the surrendered vessels into the Firth of Forth, and was afterwards charged with the surveillance of the battleship *Hindenburg*. On 15 April 1919 she left Portsmouth in company with the light cruiser *Brisbane* to return to Australia, and reached Port Jackson on 15 June. There being no immediate danger of naval war, and severe retrenchment being necessary to balance the Commonwealth budget, the battle-cruiser was soon placed in reserve. Under the Washington disarmament treaties of 1922, which limited the number of capital ships to be maintained by each of the Great Powers, the Commonwealth was compelled to 'scrap' the *Australia*, which was from the international point of view a British ship and from the British point of view obsolescent. After much discussion, during which it was proposed (*a*) to sink her off some port as the basis of a breakwater, (*b*) to turn her into a training-ship for naval trainees, (*c*) to send her to England to be sold as scrap-iron, it was decided to sink her with naval honours off the mouth of Port Jackson. All useful material having been removed, and much of her superstructure and fittings converted into mementos, the hulk—still equipped with her 12-inch guns—was on 12 April 1924 towed to sea, escorted by the *Melbourne, Adelaide, Brisbane, Anzac,* and *Stalwart,* and saluted as she went by the light cruisers of a British Special Service Squadron which, under Sir Frederick Field, was visiting Sydney during its tour of the world. Then, 24 miles due east of Port Jackson heads, the *Australia* was sunk in 150 fathoms.

Australia, Naming of. The use of some derivative of the Latin word *australis* for regions south of the equator is as natural and as little significant as the use of 'oriental' and its allies for regions east of Europe. That any land discovered in the southern hemisphere—outside Africa and South America, which already had names of their own—should be called (and mapped as) *Terra Australis,* or even (as de Brosses in 1756 called it) Australasia, needs little note and no explanation. But the specific names 'Australia' and 'New Holland' do need some explanation, and are dealt with here.

The earliest deliberate use of the word Australia is in an index to the Dutch *General Description of the Indies,* published in 1638. In the body of this book the word does not occur, nor does any allusion to the continent now so called; but a voyage made by Le Maire and Schouten in 1615-7 round South America via the Solomons and northern New Guinea to Java is called 'Australische Navigatien,' and the indexer refers to some passages in the account of this voyage as 'Australia Incognita Ontdeckt' (i.e. 'Unknown Australia Discovered'). Here, however, the word merely means 'southern lands,' and has no reference to our continent. Curiously enough a certain John Dunton, translator of de Foigny's *La Terre Australe Connue*—the scene of which is laid in or near South America—managed in 1693 to hit on the same word, rendering 'Terre Australe' by 'Australia;' and in 1770-1 Dalrymple used the name to designate an area east of South America. So the word existed long before it was applied as it is at present.

It so happens, however, that as a misprint 'Australia' had occurred even before 1638. In 1606 de Quiros discovered the New Hebrides and, believing that the island on which he landed was part of a great continent, named it 'Austrialia del Espiritu Santo' in honour of his king (Philip III of Spain, who was an Austrian prince); he intended this name to apply to the whole supposed antarctic continent—'all the region of the south as far as the Pole,' 'the fourth part of the world, Austrialia incognita.' But the cumbrous name was too much for most of his translators, English, Dutch or Latin; for instance, an English translation of one of his memorials to King Philip, published in *Purchas His Pilgrimes* in 1625, transliterates the name sometimes as 'Austrialia,' sometimes as 'Australia'—clear evidence that the mistake was due to accident, not to design. Later writers, however, including Hawkesworth, adopted and repeated the wrong spelling.

The genuine mainland of the present Australia, when first discovered by the Dutch (earlier discoveries—for which see AUSTRALIA, DISCOVERY OF—are still in the hypothetical stage), was at first vaguely known as *Terra Australis.* Tasman's chart of 1644 shows it as 'Compagnis Nieu Nederland,' but within ten years or so the name *Nova Hollandia* was definitely attached to it, and—translated into English and other languages as required—was for almost 200 years its official designation. It is interesting to note that in 1650 and thereabouts another New Holland was at any rate locally recognized; Martin Martini, a Jesuit missionary to China, writes of 'the island Formosa, and new Holland,' and again of 'an Island called new Holland,' as Dutch settlements off the coast of China—this was probably one of the Lu-chu group. As applied to Australia, however, the name denoted only the area W. of (roughly speaking) 135° E. long.; E. of that line, men thought for many years afterwards, there were islands, possibly, but no great extent of mainland, and the vague name was still good enough for them. Then came Cook, who assumed that his discoveries lay on 'the eastern coast of New Holland;' but this did not preclude the possible division of New Holland into two large islands by a sea-passage through the middle, such as had been used by Swift for the location of his Lilliput. When, therefore, Phillip was sent to found a settlement in the regions annexed by Cook, the western boundary of his jurisdiction was fixed by the British authorities at that degree of longitude—135° E.——which, as we have seen, was the Dutch limitation of the area along which their coastal discoveries had been made; and the custom grew up of calling all land W. of that degree 'New Holland' and all E. of it 'New South Wales.' This custom was not, however, universal. French writers of the eighteenth century frequently used the adjective '*Australien*' and occasionally the noun '*Australie*' in connection with an unknown but possible southern continent; and in 1788 a French writer of light fiction and gossip, Nicolas Edmé Restif (usually known as Rétif de la Bretonne), in a visionary account of affairs a hundred years ahead wrote of 'New Holland, which under the name of Australia is becoming a powerful empire.' This is the first known instance of the use of the word to denote the continent itself, not imaginary or then undiscovered lands. Again in 1793 a *Zoology and Botany of New Holland,* published in London, referred to 'the

vast Island or rather Continent of Australia. Australasia or New Holland.'

The man who settled the matter once for all was Matthew Flinders. As early as 1804 he was using 'Australia' for the whole continent, comprising New Holland and New South Wales; and thence onwards he fought steadily for its adoption. Joseph Banks, for reasons unknown, disliked it, and Flinders was forced to retain *Terra Australis* in the title and text of his book, though he slipped in a modest footnote advocating his real preference. But Banks was not the only autocrat in Australian affairs; he met his match in Lachlan Macquarie, who adopted the Flinders suggestion as soon as he came across it, and from 1817 onwards persistently called the continent Australia, and officially recommended the name as a substitute for 'New Holland.' The colonial office, of course, was conservative, and retained the old name for many years; in 1826 both Western Port and Shark Bay were considered to lie on the coast of New Holland (though in 'Australian Seas'), and Darling conformed to superior authority—though in 1827 he suggested the use of an official button stamped with the word *Australia* for officials of the New South Wales government. As late as 1849 the mainland was still known as New Holland by British officials, though they had by that time adopted 'Australia' to designate the Australian settlements as a whole—i.e. New Holland plus Van Diemen's Land. But long before that—roughly speaking, from the middle of the twenties—Englishmen outside official circles had followed Flinders and Macquarie, and knew 'Australia' for what it means to-day.

See Scott's *Life of Captain Matthew Flinders*, ch. xxx, and *Historical Records of Australia*, ser. I, vol. ix, pp. 867-9.

Australian. This adjective, followed by the name of some European plant, makes names for many Australian plants that are supposed to resemble in one way or another their European namesakes. Among them are Australian Celery, for which see APIUM; A. Edelweiss, see COMPOSITAE; A. Heath, see EPACRIS; A. Lilac, see PROSTANTHERA; and A. Shamrock, see TRIGONELLA.

Australian Agricultural Company. Among the numerous recommendations of Commissioner J. T. Bigge (q.v.) was one, based on the work done and the results obtained by John Macarthur, that 'settlers possessing capital and a real intention of pursuing the same beneficial course of industry' should receive grants of land in New South Wales 'in proportion to the number of convicts they engaged to employ and to the numbers of sheep and cattle they took with them.' Attracted by this suggestion, John Macarthur junr. and 11 English capitalists (including three members of parliament) in April 1824 formed in London a company with £1,000,000 capital to take up a million acres 'for the purpose of raising fine wool and, subordinate to that object, cultivating the vine, olive, flax, and other productions now imported from the shores of the Mediterranean.' It was further proposed to make special attempts to improve the morals of assigned convicts: to introduce German, French, and Swiss labour for the expert treatment of the wool, etc.: and to pay particular attention to female emigration. Lord Bathurst, then colonial secretary, took great care to ensure the public advantage—he approved, for instance, of olive-growing, but suggested that vineyards on a large scale might interfere with the wine export trade of the Cape Colony: and on 21 June 1824 the company was approved by act of parliament.

The directors at once appointed a local committee of advice, consisting of John Macarthur's nephew Hannibal, son James, and son-in-law James Bowman, Archdeacon Scott (who refused to act and was replaced by Saxe Bannister) and P. P. King: this committee seems to have done nothing except talk to the surveyor-general, John Oxley, who recommended (*a*) Liverpool Plains, (*b*) Port Stephens, as a site for the settlement. As agent and manager the directors appointed Robert Dawson, who on 26 June 1825 sailed from England in charge of 80 settlers, 720 sheep, 15 thoroughbred horses, and 12 head of cattle. A five months' voyage brought them to Sydney: on 1 January 1826 Dawson, with a party that included Henry Dangar (at that time assistant surveyor under government), proceeded to Port Stephens, and by May 1826 the settlers and stock were on the land. Jesse Gregson, the historian of the company, points out how hasty and superficial were the measures taken to secure suitable land, laying the blame partially on Dawson but mainly on the local committee. Within a year the obvious results followed: distracted between the proposals of the English directors (who wanted to add silk, tobacco, sugar, and cotton to the already long list of desired products), the competition with private settlers for assigned servants (which was rapidly earning the company great unpopularity), and the difficulty of growing fine wool either on the coarse coastal pasturage or in the rough country inland, Dawson let the settlement run to seed and was in the end suspended by the local committee. John Macarthur himself, taking charge for a time, came to the conclusion that success was impossible, and the enterprise was on the brink of failure. At that moment the British government—which had benefited considerably by the company's absorption of convicts—offered to hand over to it the coal-mines at Newcastle, which under government control had never been a success. Both the local committee and Governor Darling raised strong objections; but the authorities in England, at both the colonial and the company's office, persisted, and in June 1830 the company received a grant of 2000 acres of the Newcastle coal-field, with a practical monopoly of coal-mining in New South Wales for 31 years. (The British law authorities denied that it was a monopoly, but the result was the same.) Already in 1829 the directors had cancelled the appointment of the local committee and made Sir W. E. Parry (q.v.) sole manager ('commissioner') of the company's Australian properties. He reached Sydney at the end of the year, and at once inspected and condemned the greater part of the Port Stephens grant: the English directors obtained from their government an order directing the governor of New South Wales to allot them about half a million acres somewhere in the interior, the company surrendering an equivalent area at Port Stephens: and Henry Dangar—who had left the government service and joined the company's—discovered for them two fine blocks of land on or near the Liverpool Plains. This land was outside the region where settlement could legally be established, but a few cattle- and sheep-owners were 'squatting' there (among them John Blaxland and William Dangar); and Bourke in 1832 refused to let the company take the desired areas, as he held that the men actually living there should have first choice if the land was to be thrown open at all.

The directors, however, appealed to the British government and had Bourke's decision reversed: and the poorer part of the land at Port Stephens —which had been selected by the company's own officials, not thrust on them by the government —was exchanged for the two fine stations (about 600,000 acres in all) afterwards known as Warrah and Goonoo Goonoo, the one behind Quirindi, the other facing Tamworth across the Peel River. Parry also finalized the Newcastle transaction, and in 1831 was selling coal to the public.

From this time onwards the company prospered. Parry, retiring in 1834, was succeeded by Henry Dumaresq, and he, dying in 1838, by P. P. King —in whose time James Brown, by opening a coal-mine near Maitland, challenged the company's monopoly and, though the legal decision went against him, procured the abandonment of the company's privilege. At the same time the then colonial secretary, Earl Grey, gave the company its title-deeds to the whole of the properties it was in possession of. At the end of 1849, for financial reasons, the office of commissioner was abolished, and A. W. Blane, one of the board of directors, who was sent to reorganize the Australian establishments recommended that the Goonoo Goonoo station should be sold. Unwilling to let so valuable an estate (on which gold had just been discovered) pass into other hands, the directors merely formed a new company—the Peel River Land and Mineral Company—composed almost entirely of shareholders of the old company, which took over Goonoo Goonoo and put it under the management of P. G. King, while Warrah, the Port Stephens grant, and the Newcastle mines remained in the hands of the Australian Agricultural Company, with M. F. Brownrigg as manager. The result of these operations was, to quote the directors' report, that 'the original capital of the Australian Agricultural Company will virtually be paid back to the proprietors, with an addition of £15 per share, while the Company will retain two valuable estates of more than 700,000 acres, the north shore of the harbour of Port Stephens, its extensive property at Newcastle, and a coal-field of 2000 acres, together with a contiguous property of 2000 acres more.'

The company's history has thus far been treated in some detail, because it exemplifies well the methods by which, when the colonial office could override the decisions of colonial governments, the land problems of young colonies were often crudely solved. From 1853 onwards the two companies became merely business organizations operating under the ordinary laws of the colony, and as such need little further discussion. The Peel River Company remained essentially a pastoral business, until its land was resumed in blocks by the State government for purposes of closer settlement (1908-20): the Australian Agricultural Company, on the other hand, while retaining its stations, became in the public eye more and more associated with coal-mining, especially after its Gloucester (Port Stephens) estates were resumed by the State government in 1903. Large hematite deposits were discovered near Pumpkin Point in 1856, but were not exploited until 1874, when the ore was found too intractable for profitable use. In 1908 the company began to split up its lands at Warrah, selling a large block for closer settlement; the State government resumed 45,000 acres of the same estate in 1912, and the company in 1915 and 1922 sold other blocks—so that the Warrah estate, originally comprising about 250,000 acres, was at the end of 1922 reduced to about 113,000. The company's principal coal-mine (the 'Sea Pit' colliery) being exhausted in 1914, it abandoned that branch of enterprise, selling its other colliery (at Maitland) to a Victorian company.

See Gregson's *The Australian Agricultural Company, 1824-1875*, a valuable and authoritative history by a former manager of the company.

Australian Imperial Force, THE. (For convenience' sake this narrative deals not only with the A.I.F. proper—i.e. the military divisions which fought in Europe and Palestine —but also with the small expeditionary force which was sent to New Guinea soon after the outbreak of war, and the volunteer detachments which served in Mesopotamia, the Caucasus, and European Russia.)

During the world-war of 1914-18 Australians fought in three continents and became known to the people of almost every nation. They fought in the snows. They fought in the tropics. They fought in every element—air, land, sea, and under the sea. The records of the land and air forces only show that, first and last, the total number of troops raised in Australia for the war was 416,809, of whom 330,000 were sent overseas; the total casualties in all theatres of war were 226,073. The percentage of casualties to the total numbers engaged was greater for Australia than for any other part of the Empire, as the above official table, furnished by the British war office, shows.

Country	Troops raised	Troops sent overseas	Total casualties	Killed, died and missing	Percentage cas. to numbers engaged
United Kingdom	5,704,416	5,000,000	2,626,743	1,010,001	52½
Canada	628,964	411,834	210,151	60,425	51
Australia	416,809	330,000	226,073	59,258	68½
New Zealand	105,629	99,822	57,887	16,483	58
South Africa	228,907	* 228,907	18,718	7,274	8¼
Newfoundland	11,922	11,922	3,509	1,195	30
India	1,401,350	953,374	104,684	43,695	11

*Includes 92,837 coloured troops used for labour and transport. South Africa was a theatre of war.

The N. and M.E.F.—At the outbreak of war in August 1914 Australia's most immediate anxiety was to discover the whereabouts of the German Pacific squadron, whose ships had not been located since mid-June: as their nearest base for an attack on Australia was at Simpsonshaven in New Britain, the Australian squadron was sent there to look for them. On 7 August the federal government received from London an official message suggesting that the seizure of the German wireless stations at Rabaul, Yap and Nauru would be 'a great and urgent Imperial service.' Volunteers were at once called for, and on 19 August Colonel William Holmes left

Sydney in the troopship *Berrima* with about 1500 men—six companies of the naval reserve, a battalion of infantry, two machine-gun sections, and signalling and medical detachments. This force, after eleven days' training at Palm Island off the Queensland coast, reached Blanche Bay in New Britain on 11 September, escorted by H.M.A.S. *Australia* and three destroyers. At 6 a.m. on that day two parties of naval reservists (25 men in each) landed at Kabakaul and Herbertshohe (now Kokopo) with orders to discover and capture a wireless station that was known to exist somewhere inland. The Kabakaul party, after advancing about two miles, came under rifle fire from a small entrenched position across the Bitapaka road: reinforcements were quickly landed from the destroyers and the *Berrima*, and the enemy surrendered. The wireless station was captured that evening. Two Australian officers and three seamen were killed, and four seamen wounded—the first Australian casualties in the war. The Herbertshohe party penetrated five miles inland without opposition, and then returned to the coast. On the 12th Rabaul was occupied without opposition by the infantry, and next day the military occupation of the island was formally proclaimed. The German governor had retired to Toma, about ten miles inland, but a raid towards his headquarters on the 14th, aided by a few shells from the *Encounter*, brought him to terms, and on the 17th he signed a capitulation which, though it did not formally surrender any territory, guaranteed that throughout German New Guinea (a name involving all the German colonies in the Pacific except Samoa) no resistance should be offered to British occupation. On the 21st the enemy troops, German and native, laid down their arms, and on the 24th Friedrich Wilhelmshafen (Madang), the chief settlement on the New Guinea mainland, was occupied without resistance. The occupation of the outlying islands proceeded leisurely: Kaewieng in New Ireland was taken on 21 October, Nauru (whose wireless station had been destroyed by the *Melbourne* on 9 September) on 6 November, the Admiralty group on 21 November, and Bougainville and Buka on 9 December. During the next two months the greater part of the original expeditionary force was returned to Australia, leaving behind it a small administrative body to carry on the government of the colony, which was until the end of the war considered to be German territory under temporary military occupation.

Origin of the A.I.F.—On 3 August the Australian government cabled to Britain on offer (*a*) to place the Australian navy under the orders of the admiralty, and (*b*) to send 'an expeditionary force of 20,000 men of any suggested composition to any destination desired by the Home Government.' The offer was promptly accepted, and Australia set about creating the force which General Bridges even then spoke of as 'the 1st Australian Division.' Before many days had passed, its title, in order to avoid confusion with the expeditionary force sent to German New Guinea, became the Australian Imperial Force—subsequently immortalized as the A.I.F. In the event, the First Convoy carried rather more than one division of Australian troops, for there were four infantry and two light horse brigades (including one of each from New Zealand).

The transports left Albany (the port of concentration) on 1 November 1914, and landed in Egypt early in December. The destination of the Australian force had for long been matter for conjecture. The original intention was to send it through the Suez Canal to Europe; when a rebellion broke out in South Africa, a countermanding order (of 25 October) diverted the convoy to the Cape, but on 31st this was revoked, as Botha had defeated the rebels. The final destination of the troops was, however, again altered—and thereby, perhaps, the course of the war—by the intervention of Sir George Reid, the Australian high commissioner in England. The war office was preparing camps for all Dominion troops on Salisbury Plain, but not enough huts were ready, or procurable in time, for all the contingents expected; and Sir George Reid represented to Lord Kitchener in person the danger of bringing troops from a warm climate to the bleak Salisbury Plain in winter, with no shelter but tents. Kitchener, surprised that the war office contract for the erection of huts had not been completed, agreed with Reid, and suggested that the Australians should undergo their war-training in Egypt; the Australian government approved, and General Bridges, who was in command of the expeditionary force, received at Aden a wireless message informing him of the new plans. On 3 December disembarkation began at Alexandria.

In Egypt the first task was organization. When they arrived the troops met for the first time General Birdwood, whom Kitchener had appointed to command them, and his chief-of-staff Brigadier-general H. B. Walker, afterwards G.O.C. the 1st Australian division. As a second convoy with another Australian infantry brigade (the 4th), two more light horse brigades, and certain lines-of-communication troops (motor transport and hospitals), was due shortly, Birdwood decided to form an army corps of three divisions, two infantry and one mounted; the existing Australian division under Bridges, a 'New Zealand and Australian' division (the 4th Australian brigade, the New Zealand infantry brigade, and a third if it could be procured), and a mounted division of three Australian light horse brigades and the New Zealand mounted rifles. But some of these troops were still on their way; to avoid delay, therefore, one Australian and one N.Z. mounted brigade were incorporated in the 2nd division, the 3rd division remained imaginary, and the 2nd and 3rd Australian mounted brigades were kept as corps troops. The army corps was named 'Australian and New Zealand Army Corps,' and the clerks at Birdwood's headquarters coined from its initials (shown on a rubber stamp used for registering correspondence) the word 'Anzac,' which early in 1915 was adopted as the corps' code name, and eventually became famous.

In February 1915 some fighting on the Suez Canal ended in the repulse of a Turkish attack, made partly with the idea of encouraging internal trouble in Egypt; but no insurrection actually occurred until the end of 1915, and then only among the western desert tribes. The Australians and New Zealanders were first launched into the war in 1915 in the campaign for the Gallipoli peninsula—an attack aimed at the heart of the Turkish empire in order to crush the Germans' eastern ally, to open permanent and safe sea communication with Russia, and to swing Balkan opinion to the side of the Allies. The enterprise began in February as a naval demonstration against the Dardanelles forts—a mere threat to frighten Turkey and relieve Turkish pressure on the Russians in the Caucasus. While plans were being discussed for the naval bombardment, Winston Churchill (then first lord of the admir-

alty) urged co-operation by a Greek army to be landed on the peninsula; but the use of Greeks was vetoed by Russian jealousy, and the British war office protested that there were neither troops to spare nor transports to convey them. At intervals during February and March an Anglo-French fleet bombarded the forts at the entrance to the straits in the Narrows, and managed, indeed, to silence the nearer Turkish forts more than once; but naval landing parties were unable to proceed far beyond the beach at Helles, and the fleet lost several ships from enemy mines sent adrift down the channel. Only when the moment of surprise had passed and several weeks had been spent in fruitless attempts to prove that the navy by itself could force the straits, was it recognized that military co-operation was necessary. Then General Sir Ian Hamilton was sent out from England to take command of the army for the proposed landing, the troops allotted for it being the Australians and New Zealanders in Egypt, the royal naval division (also in Egypt), and the 29th division (sent out from England). There was also a French division under General d'Amade, some troops of which on the day of the landing made an attack on the Asiatic shore by way of creating a diversion. Hamilton assembled his troops at Lemnos, as his advanced base, and on the evening of 24 April the assaulting divisions were carried in transports and warships to the points selected for attack. The main blows were to be delivered by the 29th and royal naval divisions and the French division at five beaches near Cape Helles, and by the two Anzac divisions at a beach just north of Gaba Tepe. The southern attack aimed at seizing Achi Baba height and the Kilid Bahr Plateau, and the northern attack the eminence called Mal Tepe, the occupation of which would isolate the Kilid Bahr position. By way of diversion, part of the royal naval division was to make a feint at landing near the Bulair lines, at the extreme neck of the peninsula, and a French force was to land on the Asiatic shore.

Landing at Anzac.—The landings were most gallantly made at about dawn on 25 April; but in the two months which had elapsed since the first naval bombardment the Turks, well warned of what might follow, had vastly improved the military defences of the peninsula. The assault, which on 19 February might have overrun the desired plateau in a few hours, was parried on 25 April among the tangled foothills and valleys, despite heroic efforts on the part of the attacking troops to push through. After a whole day's desperate fighting the 29th division made good a landing at Helles, and the Anzacs at the beach afterwards called Anzac Cove; as a matter of fact, they landed nearly a mile farther north than had been intended—an error due to movement in the dark against a shore current, and to the anxiety of the boats to make the beach without delay or alarming hostile sentries. The troops selected to lead the assault, (Maclagan's 3rd Australian infantry brigade) dashed from the boats under a hot and increasing fire, having been discovered before the first keel grounded. Pell-mell into the bush of the lower slopes, and thence up to the steeper ridges and valleys, rushed little parties of the first four battalions, separated inevitably by the confusion of the landing and the natural obstacles they encountered. McCay's 2nd Australian brigade, arriving soon afterwards, had been intended to advance on the left of the 3rd and cover that flank; but Maclagan's urgent appeals for assistance made McCay direct his men to follow the 3rd brigade up the valleys, now resounding with the din of the Turks' artillery and machine-guns. MacLaurin's 1st brigade was pushed on, as it landed, in support of the 2nd, and the attack on the left flank fell to the share of the Anzac division, whose brigades stormed high ground afterwards known as Plugge's Plateau and Walker's Ridge. By the end of the day some sort of a line had been formed in a roughly circular position, its farthest points some 2000 yards east of the beach. It had become fixed there as the battalions, much mixed and weakened by losses, fell back from successive Turkish counter-attacks. Some few men of the 2nd and 3rd brigades penetrated that day as far at Battleship Hill and almost to Gun Ridge, nearly twice as far out as the ultimate rallying line. Throughout the night of the 25th and the following two days Turkish counter-attacks were almost continuous—so persistent, indeed, that for three days the Anzac line could not be sorted out into battalions again, or the men themselves allowed any rest.

The object of the landing had failed, and thenceforward for three months operations consisted mainly in improving the narrow positions won. An attack on 2 May (by New Zealanders and Australians) on the hill called Baby 700, leading to the ridge of Sari Bair, was unsuccessful, as was a smaller attack by a party of the 11th Australian battalion on Gaba Tepe peninsula, south of Anzac Beach. At Helles, too, repeated efforts were made to advance on Krithia heights; on 8 May the 2nd Australian brigade and the New Zealand infantry brigade co-operated at Helles with the royal naval division in one such limited advance against a murderous machine-gun fire. On 18 May—this force having fortunately been moved back to Anzac in time—came the strongest Turkish effort of the campaign to drive the Anzacs back into the sea. From 2.30 a.m. for seven and a half hours the Turks hurled themselves repeatedly against the whole Anzac front, especially at the centre; but at 11 a.m., when the attack began to die down, the Australian trenches were still intact, and some 3000 enemy dead strewed the ground in front of them. The casualties were so heavy that on 24 May an armistice was arranged for burying the dead. This defeat, followed by another on 29 June in a determined attack against the angle of the Australian line known as the Nek, established the tenacity in defence of the Dominion infantry and sharply cooled the enemy's ardour.

The Suvla Fighting.—Sir Ian Hamilton was convinced that he must have a considerably increased force before he could win the summits which commanded the straits, and has recorded his reasons for believing that, if the troops he requested had been sent to him, he could have won the campaign. In May he asked the war office for two army corps. Ultimately five more divisions were sent to him; but his strength on paper was gravely misleading, for (as he repeatedly pointed out) reinforcements were not furnished to make up the losses in all divisions. In these circumstances the weekly wastage in the line at both Helles and Anzac was alarming. Hamilton realized by July that he must make the best of what troops he had, and that to delay action while he reiterated his representations about the rifle strength of his divisions would make his position grow steadily worse. In short, he had to attack while his divisions were still strong enough to do so. He decided to land two extra divisions each at Helles and Anzac, to launch a

combined assault, and then to throw ashore the 11th division and two brigades of the 10th at Suvla Bay, 'to capture hill 305, and, working from that dominating point, to grip the waist of the peninsula.' The battle began at the end of the afternoon of 6 August. At Helles the 29th and 42nd divisions fought desperately to gain 'the Vineyard' in the centre of the Turkish position, and for seven days a violent struggle continued here, but without more than the slightest local success. Simultaneously with the beginning of this attack the 1st Australian brigade was flung into a ferocious assault on the Turkish position at Lone Pine. That engagement was perhaps the fiercest of the whole campaign. The enemy trenches were roofed over with logs, and the fighting in those vaulted ways when the Australians entered—tearing holes in the roof, or finding a way by some communication trench—was of the bloodiest description. Three trenches were taken in this fashion; then followed a second hand-to-hand conflict, a Turkish counter-attack. For three days counter-attacks continued, but Lone Pine was held. Meanwhile on 7 August the remainder of the 1st division and the dismounted light horse were badly mauled in another attack from a series of famous posts towards Mortar Ridge and Baby 700. The effort wilted under a concentrated fire, but was noteworthy for the gallantry with which successive waves of light horsemen charged forward, knowing they were going to certain death. Their attack was practically wiped out. The main attack on Sari Bair, also on 6 August, was delivered by a mixed force of about two divisions under General Godley, which advanced from Ocean Beach just north of Anzac. This attack was intended to link up with the planned surprise advance of British troops from Suvla Bay. The New Zealanders advanced successfully to a position under Chunuk Bair. To their left the 4th Australian brigade moved up one branch of the Aghyl Dere, and a Ghurka brigade up a second branch of that gully, till they joined the New Zealand flank on Rhododendron Spur. Here the troops dug in before strong forces of the enemy on the lower slopes of Sari Bair ridge. At dawn on 8 August, the expected support on the left flank from the Suvla Bay force not having appeared, the New Zealanders on the right again attacked towards Chunuk Bair and the 4th brigade towards Abdel Rahman ridge. Between these two columns Indian infantry and some British battalions fought forward towards Hill Q, north of Chunuk Bair, and some few of the attackers actually reached the summit of the central ridge. They were too few to hold on. The left of the attack was entirely in the air and was being enfiladed; the Suvla Bay force was still missing; but the objective was so nearly won on Godley's front that a further attack was ordered for dawn on 9 August. A British supporting column of five battalions under General Baldwin, marching up to deliver the decisive blow, lost its way and arrived late. Some of the South Lancashires and the Ghurkas actually reached the col between Hill Q and Chunuk Bair, whence for the first and last time they looked down on the straits; but the support of Baldwin was lacking, and they were speedily driven back by overwhelming numbers of Turks. Baldwin's attack came too late to succeed. The opportunity was lost; the 4th Australian brigade on the left was nearly surrounded and had to fight its way back; and on 10 August two British battalions (which had relieved the exhausted New Zealanders on the slopes of Chunuk Bair) were overwhelmed by about twelve times their number of Turks.

The most tragic failure was perhaps at Suvla, where General Stopford's force (the 11th division, plus two brigades of the 10th) was landed during the night of 6-7 August. The surprise of the landing was complete; there was practically no opposition at the beach or beyond it; but, instead of pushing on with every available man, the force wasted nearly twelve precious hours over assembling in the sand dunes. Patrols sent out had on 8 August reached a point five miles inland. Anafarta plateau could apparently have been occupied with ease, but was not, and no effort was made to support the flank of the attack on Chunuk Bair farther south. On the night of the 8th the Turks hurried troops to parry this unexpected landing, and when on the 9th Stopford's force advanced towards the high ground south of Tekke Tepe, they were driven back. The opportunity here—a far more favourable opportunity than at Hill Q, and one deliberately created—had also vanished.

Hamilton demanded a further effort before he finally gave up hope, and on 21 August the 11th division was ordered to attack across Anafarta Biyuk valley, while the 29th division attacked Scimitar Hill, and a mixed Anzac force moved on Hill 60 (on the flank of the 4th brigade's advance of the 8th). Hill 60 had in the interval been converted by the enemy into a strongly fortified position, and not till the 27th did a final attack establish the Australian line across the summit. In this fighting, which lasted continuously for a week, troops of the 2nd Australian division, newly come from Egypt, took part. At the end of August the 2nd division and the British 54th division took over the Anzac line from the original Anzac divisions, which were withdrawn to rest at Mudros. The battle for Hill 60 was the last fight of the campaign. An interval of inaction followed, attended by dysentery and other sickness, heavy rains, and the first of the winter gales. By October the war office was foreshadowing the evacuation of the peninsula.

The Evacuation.—This evacuation was probably the most skilful exploit in the Gallipoli operations. In October Hamilton, in reply to war office enquiries, estimated that withdrawal would involve the loss of 50 per cent of the force, but Monro, who took over the command, declared unhesitatingly for evacuation. Kitchener himself visited the peninsula in November, and on 8 December Monro ordered Birdwood to proceed with the evacuation of Suvla and Anzac. Between that date and the 20th it was carried out with exemplary skill. The enemy was completely deceived. A few guns were destroyed at the last, and considerable quantities of stores on the beaches were set on fire; but under the arrangements devised by Birdwood and his staff 80,000 men, 5000 horses, and 200 guns were withdrawn from this portion of the peninsula without any casualties, and without any suspicion on the part of the Turks. Three weeks later—on 8 January 1916—the troops at Helles were withdrawn with similar success and immunity from molestation. The total Gallipoli casualties (including French and naval) were 33,532 killed, 78,518 wounded, and 7689 missing. Of these the Australians had 8587 killed and 19,367 wounded.

Reorganization.—At the close of the year the Australians and New Zealanders were re-transported to Egypt. Some light horse and a company of the Australian camel corps took part,

along with mixed detachments of the Egyptian garrison, in the short December campaign against the Senussi, whose incursion into western Egypt had stirred up disaffected Bedouins. There was smart fighting in the desert west of Alexandria during December, January, and February, but by March the rising was crushed, and the Senussi abandoned their effort. The winter and the early spring were occupied in reorganizing the now greatly increased Australian army, preparatory to their expected removal to the western front in Europe. The 2nd Australian division and an extra infantry brigade (the 8th) had arrived from Australia, and a 3rd division was being raised in the Commonwealth. Available infantry reinforcements in Egypt made possible the creation on the spot of still further divisions. It was decided that each of the four original infantry brigades should throw off the nucleus of another brigade. Accordingly, working by battalions, the 1st brigade provided the seasoned nucleus of the (new) 14th brigade, the 2nd parented the 15th, the 3rd the 13th, and the 4th the 12th. This enumeration was dictated by reason of the fact that the numbers 9, 10 and 11 had been allotted to brigades of the 3rd division then being formed in Australia. All brigades were then raised to normal strength again by the addition of raw troops, reinforcements from Australia. Then the 4th, 12th, and 13th brigades were assembled into the 4th division under the command of Maclagan, and the odd 8th brigade was amalgamated with the 14th and 15th brigades into the 5th division, under McCay. Monash left the 4th brigade to take over command of the 3rd division when it arrived in England; Walker remained with the 1st division, and Legge with the 2nd. Birdwood was now given command of the 1st Anzac corps (1st, 2nd, and 4th Australian divisions), and General Godley of the 2nd Anzac corps (New Zealand division, 5th Australian division, and a British division later attached). Other reorganization plans created the Anzac mounted division (1st, 2nd, 3rd light horse brigades and New Zealand mounted brigade) under General Chauvel, and the Imperial camel corps. The latter began as a composite camel battalion, formed by two sections selected from each Australian infantry brigade; a second battalion was composed of English and Scottish territorials, a third (later) of Australians and New Zealanders, and at the end of 1916 a fourth of Australians. The camel corps was disbanded in May 1918, and two new light horse regiments formed from it were added to the Australian mounted division—which began as the 'Imperial' mounted division, and was formed early in 1917 by amalgamating the 5th (British) yeomanry brigade, the 4th A.L.H. brigade, and the 3rd A.L.H. brigade (from the Anzac mounted division). The name 'Australian mounted division' was given it about the middle of 1917. These two mounted divisions and the camel corps made up the desert mounted corps, renowned later in the Palestine campaign under General Chauvel. The artillery of the divisions was expanded in much the same fashion as were the infantry units. Later on in France, machine-gun battalions and trench-mortar batteries, when these were added to the infantry fighting power, were also built up, each from a trained nucleus.

Another arm of the A.I.F. which grew from a small detachment into a field unit, and threw off the material for other units as required, was the Australian flying corps. This service began with the half-flight which served in the first Mesopotamian campaign in General Nixon's force. Four Australian flying officers and 41 mechanics and others, with sundry technical equipment but no aeroplanes, left Australia for Mesopotamia early in 1915. In the fighting during that year up to the battle of Ctesiphon one of the Australian airmen was killed and two were captured; the fourth later on entered the Royal Air Force. Of the mechanics and aerodrome personnel, nine were besieged in Kut and later surrendered with Townshend's garrison; two only of the nine survived the rigours of prolonged captivity in Turkey. After this first Mesopotamian campaign the remaining mechanics of the half-flight were despatched for service with the No. 1 Australian flying squadron, then forming in Egypt. This squadron had been raised in Australia and sent to Egypt for war-training; it arrived there in April 1916, began active service in detached flights a few weeks later over the Canal and in Upper Egypt, and took a prominent part in operations throughout the Palestine campaign. Some of its pilots and observers (flying officers) and skilled aerodrome personnel were later ordered to England to provide an experienced leaven for a new 2nd squadron, raised in Australia and sent to England towards the end of 1916. The 3rd and 4th squadrons were built up in much the same fashion round a nucleus of trained and tried officers and mechanics. The 2nd, 3rd, and 4th squadrons served from the end of 1917 till the Armistice on the western front in Europe. Behind each fighting squadron was formed a training squadron at the base—in Egypt and in England respectively—and by 1918 there had sprung up in England a complete Australian training wing, providing reinforcements of flying officers and mechanics for the squadrons at the front.

First Year in France.—Reorganization completed, the Australians were soon required for further fighting. Between March and June 1916 the four infantry divisions were transported to France, and the mounted divisions prepared to take part in the advance of the eastern army under General Murray through the Sinai peninsula. The A.I.F. was thus divided, and from this time forward fought in two separate theatres of war. This narrative is concerned first with the infantry divisions in France, which first went into the line south-east of Armentières, in what was known as 'the nursery sector.' To this sector, the quietest on the British front, were sent all new divisions for 'breaking-in,' and all exhausted divisions requiring a rest. The Germans used this sector in much the same fashion, and Lille, behind the German line, and Armentières, behind the British, were spared, as though by tacit understanding, the artillery bombardment inflicted upon other towns near the front.

While the 1st Anzac corps (1st, 2nd, and 4th Australian divisions), concentrated near Amiens, was preparing to support the Anglo-French attack along the Somme, the 5th Australian division and 61st British division attacked on 19 July from the south of the 'nursery sector' towards Fromelles, with the object of pinning to that front certain German reserves. These fresh troops were about to be withdrawn to the Somme, where the enemy's position had become highly critical; German official narratives published since the war have confirmed what was then suspected, that about the third week of July the weight and succession of British blows on the Somme had very nearly effected the desired 'break-through.' The Verdun offensive was

definitely abandoned; all the enemy's reserves of energy were wanted to hold the Allied offensive, and any operations which prevented or delayed the despatch of fresh German troops to that region of decisive battle were of the utmost service. At Fromelles, therefore, the Australians were fighting the Somme battle as effectively as though they were on the spot. That, however, was not the view they held at the time. The attack penetrated the German lines but failed to hold any part of them; the Australian casualties alone were over 5500; and the failure was declared to be the result of inadequate co-operation on the flank and of non-provision of supporting troops. The heavy day's fighting, however, was distinguished by the gallant conduct of the Australian troops under intense fire.

On the Somme battle-field the Allied offensive had been in progress for three weeks when the Australians first entered it. The Anglo-French attack had bitten out a large piece of the German line, but had come up against several strongly fortified localities, the speedy reduction of which would, it seemed, ensure a clean breach into the open country towards Cambrai and St. Quentin. Against one of these fortified strong-points, Pozières village, the 1st Australian division was sent in on 23 July. It required nearly 48 hours' fighting to win the whole of the village, and the enemy's counter-attacks were especially heavy. The 2nd division then took over the attack and, after a week's stubborn fighting, finally won and held the strong trenches east of the town known as OG1 and OG2, and the famous Windmill position. The Australians were here both sternly tested and fiercely enraged by the Germans' use of *flammenwerfers*. On 7 August the 4th division (which had relieved the 2nd in the line) repulsed decisively a heavy German attack on Pozières, and three days later began a new advance against the next series of strong-points based on Mouquet Farm. Each of the three divisions, in turn or in company, struggled hard for the possession of the farm; twice during August they won it, but were forced by counter-attacks to leave it again. The German losses in these counter-attacks were enormous; one division after another shattered itself against the British line, and particularly the Australian section of it. In September again the 13th brigade of the 4th division twice entered the farm—on 3 September and again on the 5th (with the Canadians)—but each time the enemy recovered it. It fell at last on 25 September to the Canadians, after supporting works had been reduced.

During September and October the 1st Anzac corps was moved to the Ypres salient, and for some weeks garrisoned the line there, but by November it was back on the old Somme battle-field, where active operations had died down under the influence of winter cold, rain, and mud. A few minor attacks on the enemy's trenches and a few night raids for prisoners and other means of acquiring information about the German defences and line of battle, were the only relief to the grim business of holding this line through the bitterest winter of the war. The Somme mud and the Somme cold together tried all troops alike more severely than any other evils of the war. The rain was continuous in a region where artillery fire had destroyed all shelter; the trenches and the shell-torn fields dissolved into muddy bogs, where men and beasts were frequently drowned, or died of exhaustion; and the bitter cold introduced into the army the disease of 'trench-feet.' Trench-feet and influenza sorely reduced the ranks of the Australian battalions, already much worn, physically and nervously, by the preceding hard fighting. Thanks, however, to the splendid work of medical men and of the Y.M.C.A., Salvation Army, comforts and clothing funds endowed by private efforts in Britain and Australia, and similar organizations, the suffering was relieved and checked. In this work the women of the Empire played an unforgettable part.

Bapaume and Bullecourt.—The winter was long and bitter, and the Allies spent it in planning a double attack—British from Arras, French from near Rheims—on the flanks of the great German salient whose point was in front of Soissons. But while they were impatiently waiting for the weather to break, Australian troops holding a position across the Bapaume road perceived on the morning of 23 February 1917 signs that the Germans in front of them were retreating. On receipt of the intelligence British general headquarters ordered an immediate reconnaissance in force along the whole Somme front. During the last days of February and most of March there was stiff fighting with the German rear-guards—for the fact of the retreat was soon established beyond doubt—and the energetic harassing of those rear-guards jostled the enemy out of many positions ahead of his time-table. The 8th brigade of the Australian 5th division, with band playing, entered the long-desired and burning town of Bapaume on 17 March, and then through fields and along roads little destroyed by shell-fire the Australian advance proceeded rapidly for some days. On 21 March the 5th division carried Beaumetz village, lost it, and recaptured it after sharp fighting which entailed much loss on both sides. Lagnicourt was taken by the 2nd division on 26 March and Noreuil by the 4th on 2 April in two spirited attacks which stung the enemy to heavy but vain counter-attacks. A few days later the last enemy rear-guards operating in the open were chased out or captured by the Australian advance, and the corps drew up before the Germans' main position, and prepared forthwith for assault. This main position, known as the Hindenburg Line, was a multiple scheme of earthworks, reinforced by concrete fortifications, and constructed along a naturally strong strategic line linking up fortified villages, the whole defended by formidable fields of wire entanglement. Artillery and machine-gun positions were disposed along its entire length, with ranges plotted and registered. Within this defence system were arranged deep underground shelters for great numbers of men, shelters which would defy the severest bombardment. The work was performed mainly by Russian prisoners of war and by labour conscripted from villages in the occupied territory of France.

The Allied plan previously mentioned was thus foiled in its full design. Nevertheless it still offered considerable possibilities, for the intended French front of attack was not involved in the retreat, and on the British front the prosecution of the offensive offered prospects of gaining the Vimy Ridge, relieving the German pressure on Arras, and turning the northern flank of the Hindenburg Line. The French attack (which was a fiasco) did not begin until 16 April, but on the 9th the British attack was commenced east of Arras, and on the 11th the 4th Australian division was sent in on the extreme right flank of the British operations against the stronghold

of Bullecourt. There was no artillery preparation, as it was intended that tanks (still a new and unfamiliar weapon) should precede the infantry and flatten out the barbed-wire. Most of the tanks were put out of action before they could carry out their task. Still, the 4th and 12th brigades seized the first line, and under a heavy fire reached the second. Unfortunately British troops on their left flank, attacking Bullecourt itself, were held up by immensely strong defences in that village, and when this and other support failed, the Australians had to fall back to their original line. Four days later came the German counter-blow. On 15 April the 1st and 2nd Australian divisions were suddenly assaulted by four picked enemy divisions without artillery warning. The weight of the blow pressed back the Australian line critically, occupied Lagnicourt village, and penetrated as far as some of the Australian artillery positions. But the Germans met a defence as stubborn and alert as their own. Australian defence posts fought their ground to the last man and stayed a deeper penetration of the rear positions, and at the right moment a magnificent counter-attack swept upon the German flank, redeemed Lagnicourt, and drove the attackers back on to their own wire. Trapped before that obstacle, they suffered terrible losses under the Australian machine-guns and artillery.

On 3 May a second and mightier effort was made by the British Third and Fifth armies to break the Hindenburg Line between Queant and the Scarpe. The Australians were again launched to attack on the right flank, between Queant and Bullecourt. Again they entered the Hindenburg Line (with the 6th brigade), but the 5th brigade on the right was held up by heavy enfilading fire from Queant, and the 62nd division (on the left) was again unable to penetrate the Bullecourt defences. Some of the 2nd Australian division (7th brigade) were thrown in against Bullecourt and assisted to force an entry, but were bombed out again in counter-attacks. Only on 12 May, after nine days of the severest fighting, and repeated efforts which drew in all local Australian and British reserves, was Bullecourt finally captured —except a last strong-point on the outskirts, which fell to the British on the 16th. On the 15th the Australians repulsed with great slaughter a massed attack on their right flank by the 3rd Prussian Guards division.

At the end of May the 1st Anzac corps was withdrawn for rest. The 4th division had preceded the others into the rest area on 14 April, after the first Bullecourt action, and was at this time attached to the 2nd Anzac corps near Bailleul, training for a coming attack at Messines. Included in this corps was now the 3rd Australian division, which had arrived in France from England at the close of 1916 and had been holding the line at Armentières. The attack on Messines Ridge, now being planned by the Second army, was really a preliminary operation in a grand British offensive on the whole Ypres-Armentières front, designed to roll up the German right flank and free the Belgian coast from the enemy's grip. The strategic objective was both the denial of the Belgian coast to German submarines and the grappling with the utmost strength of the enemy's field army. British military strength was now at its peak; the German had for some time been on the decline.

Messines to Passchendaele.—The preparations for attack on the low ridge running between Messines and Wytschaete included the firing of a series of enormous subterranean mines under the German front line. The northern end of the ridge looked directly into the southern outskirts of Ypres; from the bend in the ridge at St. Eloi the high ground swept back eastward by way of the spoilbanks of the Ypres-Comines canal, and in a rough semicircle northward again along the Broodseinde-Passchendaele ridge. This high ground had since the autumn of 1914 formed the main German position round the Ypres salient. For nearly two years Australian, Canadian, and British tunnellers had been mining in this region against the German miners; the struggle underground had been no whit less strenuous than the struggle in the trenches above; and at Hill 60—as at Loos farther south, near Lens—Australian tunnelling companies had worsted the German miners at every challenge. The biggest of all the mines for the Messines battle was under Hill 60, but there were several others near the villages of Wytschaete and Messines, which at explosion created tremendous craters. The firing of these mines at an arranged moment before dawn on 7 June gave the signal for the infantry attack. The mines themselves obliterated local enemy trenches; elsewhere the German lines had been pounded out of shape by intense artillery bombardment during the fortnight before the assault. That assault was carried out with complete success, and with astonishingly small loss to the attacking divisions, and the ridge and its reverse slope were captured over their entire length. The advance on the right flank, including the seizure of the southern end of the ridge and the village of Messines, was performed by the 2nd Anzac corps, with the 3rd Australian, New Zealand, and 25th British divisions in line. During the afternoon the 4th Australian division pushed through the New Zealanders' line and continued the advance to a pre-arranged objective. Counter-attacks in the following days were weak and ineffective.

These captures vastly improved the British front for defence, especially by affording artillery observation positions and machine-gun firing positions, which had previously served the enemy well to similar purpose. The gain of the Messines Ridge was especially useful—indeed an essential preliminary—to the British offensive at Ypres which shortly followed. The third battle of Ypres, the hardest and bloodiest of the whole war, began on 31 July, and promptly after its opening the attack was nearly drowned in a fortnight's rain. Besides having the weather to contend against, the attackers had also to meet a most skilfully arranged defence under a new system. The low-lying ground of the Ypres salient forbade the construction of deep underground dugouts, familiar features of the German defences farther south. Moreover, the enemy's faith in these subterranean fastnesses had been shaken by experience; often they had been merely traps for the defenders, unable to get out before an attack had seized the entrances, and then confronted with the alternatives of surrendering at once or being bombed in a pit. At Ypres the German defences, designed in great depth of front and sited to facilitate counter-attack, relied upon immensely strong reinforced-concrete blockhouses, extensively wired and filled with machine-guns. A heavy shell, even when it made a direct hit upon one of these so-called 'pill-boxes,' would frequently ricochet off it. Before these defences, and in weather conditions which made the shell-torn ground one vast bog of mud, the attack

was put to extreme exertion. In four months the entire British army, division by division and corps by corps, had shared in this gruelling trial of endurance, and when winter closed down the battle the German armies on the western front had been equally exhausted and even more discouraged.

The Australian infantry first entered this battle on 20 September, though artillery of the 1st Anzac corps had been engaged in support of the British since 31 July. The advance of 20 September (Battle of the Menin Road) was one of a series of leaps, each designed to recover a definitely limited strip of ground from the enemy along his entire front. The 1st and 2nd Australian divisions performed their part to the time-table and without serious loss; they drove the German line back into Polygon Wood, and the skill of their rehearsed attacking methods was more than a match for the 'pill-boxes.' On the 26th the advance was resumed on the Fifth and Second army fronts; the 4th and 5th Australian divisions took up the attack for 1st Anzac corps, and captured Polygon Wood and the outskirts of the ruined village of Zonnebeke. The most satisfactory advance of all was on the Broodseinde ridge on 4 October; both Anzac corps attacked in this advance, with the 2nd, 1st, and 3rd Australian divisions and the New Zealand division in line alongside each other, and captured the high ground of the ridge for a good half of its length. In this attack British and German plans clashed; the enemy had prepared for an attack on the front held by the 1st Australian division, and meant to launch it at almost the identical moment of the Australian assault; consequently the Australians met great numbers of German storm-troops in 'no man's land,' and completely outfought them in hand-to-hand engagements.

The weather now began to deteriorate. The 2nd Australian division carried out successfully a small advance on 9 October, and on the 12th the 3rd and 4th divisions and the New Zealanders attacked again, but, defeated by the mud and the enfilade fire together, were forced by the end of the day to abandon what ground they had taken. But the British Command was determined to occupy the remainder of the Passchendaele Ridge before the winter, and the advance was resumed in two further attacks, on the 22nd and 30th by the Canadian corps, with the 1st Australian division on its right. Finally on 6 November the Canadians in a last effort reached and held Passchendaele village and the limit of the ridge.

The close of the 1917 campaign on the western front was notable in the A.I.F. for the appearance in France of three squadrons of the Australian flying corps. No. 3 squadron (two-seater machines) arrived in September, followed later in the same month by No. 2 squadron and in December by No. 4 squadron (each consisting of single-seater fighting scouts). A number of their leading pilots had been previously attached for experience to British air-squadrons on the front and therewith had taken some temporary part in air operations during the third battle of Ypres. No. 3 squadron (Blake's), after a few weeks' front-line training in September and October near Arras, was attached to the 2nd Anzac corps at Bailleul. No. 2 squadron (Watt's) played a prominent part in the successful attack by Byng's Third army at Cambrai on 20 November—in which the 2nd Australian siege battery took part—and in resisting the equally successful German counter-attack there ten days later.

The Australian Corps.—Another landmark of this period was the reorganization of the Australian divisions. On 1 January 1918 all five divisions in France were brought together into one corps. General Birdwood retained command of the corps till May 1918, when he was promoted to command the re-formed Fifth army, and was succeeded as corps commander by General Monash from the 3rd division. The Australian corps, with No. 3 squadron A.F.C. operating as its corps flying unit, spent the winter till mid-March in the line along the Messines ridge from Warneton to Hill 60, conducting several highly successful infantry raids in strength on the enemy, and elaborating defences in depth against a German offensive, of which the Australians, in common with the rest of the British army, were warned. Meanwhile No. 2 squadron A.F.C. operated on the front of the Third army opposite Douai, and No. 4 squadron (McClaughry's) on that of the First army between Lens and Lille. They had several notable fights, and in February a flight of No. 4 squadron fought its first engagement with Richthofen's famous 'circus' squadron near Lens. A strong patrol under Cobby (No. 4 squadron) met it again, and severely mauled it, in a fog near Bapaume just before the German offensive in March.

The German Offensive.—The beginning of that offensive on 21 March 1918 at St. Quentin, and the rupture after three days of the attenuated line of the Fifth army, marked the most serious crisis on the western front since the battle of the Marne in 1914. The 2nd Australian tunnelling company was involved in the retreat of the Third army's right flank near Havrincourt Wood, and took part in the demolition of bridges and supply dumps—though this work was inadequately done, owing to the non-supply of promised explosives. By the 22nd the Australian corps in the north was, like all other British reserves and some French divisions, under orders for Amiens, to prevent the threatened separation of the Allied armies. The 3rd and 4th Australian divisions, being in rest areas behind the Messines front, were the first to go; they moved in haste, by train and motor-lorry, and concentrated about Doullens on the 25th and 26th. The 4th brigade (4th division) went into action at Hebuterne and remained there detached for nearly a month. The other two brigades of the 4th division swung south-eastwards to Albert, and occupied just in time a line on the western bank of the Ancre that barred the road to Amiens. Upon this line the British, retreating in good order but considerably exhausted, fell back during the next two days. Meanwhile the 3rd Australian division passed the Ancre and dug in across the Morlancourt ridge (between the Ancre and the Somme) from a point in contact with British units and the 4th division near Dernancourt to Sailly-le-Sec on the northern bank of the Somme. On arrival here the 3rd division immediately attacked German advance-guards and drove them back about half a mile. With the arrival of the 5th Australian division to support this Ancre-Somme line on the 29th, the 9th brigade (3rd division) was sent across the Somme to Villers Bretonneux, to assist the sorely-pressed and weary rear-guards of the Fifth army to make a stand there on the main eastern road into Amiens.

In this region the German advance was thus stopped, but on 4 and 5 April, when the enemy's

immediate reserves came up, a renewed attack was delivered in considerable strength of numbers, but without the full weight of artillery that had been assembled on 21 March. The comparative weakness of this second attack was due in great measure to the gallantry of the Allied airmen (including the two Australian scout squadrons), who from the first day of the German offensive ceaselessly bombed and machine-gunned every road by which the enemy was pressing on in his advance. The adjacent fields were still boggy with the mud of the winter; all wheeled traffic was obliged to keep to the available roads; and time and again the crowded traffic of these roads was smashed by the air squadrons, to the great damage and still more serious delay of the German supply columns and artillery. The value of this harassing work was inestimable.

Villers Bretonneux.—The attack on 5 April at Dernancourt and Albert was repulsed by the 4th Australian division and the British to the north of them. Heavy German infantry assaults were directed especially against the Australians, and penetrated the line temporarily at a point where the fire of their artillery had been concentrated to produce the utmost effect. More critical was the position at Villers Bretonneux, south of the Somme, at the other horn of this double thrust upon Amiens. Here on 4 April the 9th Australian brigade, together with the thin British line on either side of them and the French at Hangard on the Luce, withstood a blow which taxed their resistance to the utmost. Hamel village was lost and the woods near by it. So was Hangard; Hangard changed hands several times in the next few days. But the enemy's main objective was Villers Bretonneux, which would have given them a hill-position commanding Amiens and the immediate rear of the British line north of the Somme, and would have opened the principal road from the east into the city. Birdwood regarded Villers Bretonneux as the key to the whole Amiens position. The Australian 9th brigade, and the tireless British cavalry operating with them, were forced to give ground east of Villers during the morning and afternoon, but held their front intact under repeated assaults, in spite of a bombardment by high explosive and gas shells which wrecked the town behind them and smashed their communications. The line held on all day in ignorance of what had happened in its rear and on its southern flank; but towards evening the 9th brigade's right flank itself recoiled, and the enemy reached the southern entrance to the town. A desperate counter-attack, to which the last man of the meagre local reserves was committed, restored at midnight the Australian right, and for the moment the position was saved. Next evening the vanguard of the 2nd Australian division (5th brigade) arrived at Villers Bretonneux to relieve the 9th. During the next fortnight the British line here was reorganized, and the Germans made no more hurried attempts against Villers. They also were consolidating their line. There was some desultory fighting about Hangard, but of no important effect.

By the second week in April the Germans had diverted their stroke to the north. Their first blow had failed to separate the British and French armies and to reach Amiens. The able but costly retreat of the British Fifth and Third armies had minimized the effect of that blow, and the British final stand with fresh troops denied Amiens to the enemy. But the defeat of the design to shatter the British line was marked most clearly in the bloody repulse of the enemy by the Third army at Arras on 28 and 29 March. Arras was the main bastion of the whole British line at this critical period; it was proclaimed as such by the enemy's effort, by the British resistance, and by the results of the offensive in this region. In order either to turn the Arras position from the north, or to pin down British strength in Flanders, or to pursue in a new direction the advantage of the initiative which still remained to them, the Germans on 9 April assaulted in strength the line between Armentières and Bethune, thrusting their heaviest weight against a Portuguese division east of Estaires. Breaking through here, they overran the Lys flats and Armentières, and eventually the Messines ridge. At Bethune they were stayed by the valiant defence of the 51st division; but at Messines they found opposed to them divisions which had been exhausted and reduced during the previous retreat from St. Quentin in the south, and had been sent here for a rest. After a week of severe rear-guard fighting the British line, weak and with few immediate reserves, rallied in front of Hazebrouck and Caestre. The 1st Australian division, ordered south to Amiens at the end of March, had no sooner reached the Somme than it was ordered back in haste to assist the northern defence, and went into action under the low rise of Strazeele on 12-13 April. During the remainder of the month the position in Flanders remained dangerous; Bailleul was lost, and French reserves were driven off Mount Kemmel; but the line south and east of Ypres, after yielding ground hard-won during the previous year, somehow held fast, and the Germans made no more progress thereafter towards the Channel ports.

About the time of the fall of Mount Kemmel, bringing consternation to the British who had occupied it throughout the war, Villers Bretonneux was also seized in a sudden attack on 24 April by four German divisions assisted by tanks. The British 8th division here had taken over the defence of the town from the Australians, the 5th Australian division being posted in the line immediately north of Villers, before Hamel and on Hill 104. The situation called for counter-measures without loss of time, and that night the 13th and 15th Australian infantry brigades—the only fresh reserves immediately available—delivered a memorable counter-attack which began at 11 p.m. and ended at the dawn of the anniversary of the Anzac Landing. The 15th brigade attacked north of the town past the edge of Hill 104, the 13th south of the town across the flats beyond Cachy village. Each assaulting column faced considerable difficulties. The ground had been but slightly reconnoitred; the chances of losing direction on a dark night were many; the strength of the enemy was unknown; and the instructions to the troops were to neglect all flanking fire from Villers or the edge of the wood behind Villers. The plan was to squeeze the Germans in the town between the jaws of these pincers, and its success equalled the Australians' wildest hopes. By dawn the counter-attack had practically reached the old defensive line north and south of the town, and Villers was surrounded on three sides; thereafter the Germans in Villers were without difficulty killed, captured, or driven out through a rapidly closing exit. This night attack was for some months regarded, in the

public eye at any rate, as the finest Australian feat of arms on the Western front.

The ensuing three months—during which the Allied armies slowly recuperated from losses and disorganization—were marked on the British front by several brilliant minor offensive actions by the Australian corps, and on the French front by the exhaustion of the German effort. During May, June, and July the Australian corps carried out a series of attacks along the Morlancourt ridge, all limited actions by one brigade or another, and all completely successful in winning ground, exhausting the German strength, and impressing upon the enemy the superior morale of his opponents. This little campaign culminated on 4 July in the assault and capture of Hamel village and the surrounding positions by three Australian brigades (4th, 6th, and 11th), some American battalions being incorporated in the attack for instruction in this art. The careful staging of this battle by Monash, and the splendid results achieved with a maximum loss to the enemy and at very slight cost to the attack, greatly raised Monash's prestige with the British high command. Following this battle, several weeks of perpetual Australian raiding east of Villers Bretonneux reduced the nerves of the German line-troops nearly to breaking-point; and in Flanders the 1st Australian division, entrenched opposite Merris, employed precisely similar tactics and with equally satisfactory results.

The August Offensive.—Meanwhile the German offensive had exhausted itself, its last success being the penetration of the French line southwards on the Marne; this movement was thwarted and a retirement towards the Aisne compelled by Foch's counter-stroke on 15 July from the forest of Retz. While the Allied success was being exploited to the full east of Soissons, a general counter-offensive was planned, and the execution of the first stroke in it entrusted to the Australian and Canadian corps in conjunction with French troops on their right flank. On 8 August the two Dominion corps, secretly assembled in strength behind Villers Bretonneux—Australians to the north, Canadians to the south—were hurled against the German lines between the Somme and the Roye road. Behind a great array of tanks (which took the place of the usual artillery preparation) the attack went through the enemy's defences swiftly and easily. On the Australian front the 2nd and 3rd divisions pushed it to their appointed limit; then the 4th and 5th divisions, passing through them, pressed forward towards their final objective—to the consternation of the Germans, who found their artillery positions and guns submerged, their reserves broken up before they could assemble, and cavalry and fast tanks completing the wreckage in front of the assault. What this battle meant to the Germans was revealed later by Ludendorff, who said 'After this severe defeat I gave up the last vestige of hope.' The advance of six miles on the first day was continued for some distance next morning by the 1st and 2nd Australian divisions. By the 11th the enemy's resistance, stiffening south of the Somme, had been broken on the Morlancourt ridge after much difficult fighting, and the British-Australian line ran immediately west of Meaulte and Bray. The enemy's plans, whether for leisurely retreat or for a stand, were overthrown on the 22nd by decisive blows at two points. The 1st Australian division stormed the German position in the gullies at Chuigny and Chuignolles (south of the Somme, at Bray), while the 3rd Australian division advanced on the northen side of the river; and the British Third army made a new attack upon Bapaume from south of Arras. These blows set in retreat the whole German line from the Scarpe to beyond the Somme; but by the end of August the enemy, shaken but not yet broken, came to a stand on the Somme bend at Péronne, and on the high ground that runs northwards by Mont St. Quentin to the Bapaume plateau.

Mont St. Quentin.—Along the Somme valley the Australian 3rd and 5th divisions conducted the pursuit of this retreat with all energy, and, as soon as resistance stiffened, again prepared to attack. The 5th division found the Somme crossings south of Péronne strongly held; the 3rd found the Germans in strength on rising ground beyond Clery—the Bouchavesnes spur and Mont St. Quentin; as soon as it could come up, the 2nd division thrust its 5th brigade between the 3rd division and the Somme. At dawn on 31 August the 5th, 10th, and 9th brigades in line began the assault. A determined and successful attack of the 9th on the Bouchavesnes spur enabled the left and centre of the advance to reach the main Péronne-Bapaume road; the 5th won the summit of Mont St. Quentin, but during the afternoon was obliged by heavy counter-attacks upon a weakened line to give some ground. Next day the 6th brigade (2nd division) retook and held Mont St. Quentin, while the 11th brigade (3rd division) pushed on the left to Allaines; but the main burden of the battle on this second day was borne by the 5th division in its advance on Péronne. The town had many facilities for defence, and was strongly defended; the 14th brigade, attacking from north of the Somme, eventually secured a footing in the western part of Péronne, while the 15th found a crossing over the river opposite Flamicourt, and thus joined up inside Péronne with the right of the 14th. A renewed attack on 2 September by these troops, aided on their left by the 7th brigade (2nd division), forced the Germans out of their remaining hold on this strong position, and by the 5th the enemy was in full retreat again. About five days later he came to another stand in front of the Hindenburg Line, in what had been the British line of early 1918, and was now known as the Hindenburg Outpost Line. Meanwhile, on the 2nd the Canadians had already overrun the northern end of the Hindenburg Line (the Drocourt-Quéant sector) in a smashing attack. The effect upon the enemy of the blows of August and early September was so considerable that the Allied high command revised its calculations for a conclusion of the war in the spring of 1919, and resolved to press its present advantage to the utmost. On 12 September the Americans (assisted by the French) drove the Germans out of the big salient at St. Mihiel in Alsace, which the enemy had occupied since the beginning of the war. A fortnight later the King of the Belgians led a combined Belgian, British, and French attack from Ypres, which tore down the remaining enemy defences on the sea-flank, and opened the advance on Antwerp and Bruges. A timely defence of their centre seemed the Germans' only hope of averting a mightier and an avenging Sedan. This defence depended absolutely on the central section of the Hindenburg Line, and upon this three British armies threw their full weight.

The Hindenburg Line.—On the front of the British Fourth army the assault was begun on 18 September, when the 4th and 1st Australian

divisions attacked in the centre of that army's line, with British divisions on either side of them. The effort was completely successful, and on the Australian front was remarkable for the unexpectedly light cost in casualties. Except for a difficult locality on the Fourth army's left front, the whole of the Outpost Line was taken. This action brought the army directly against the Hindenburg main line, and, as soon as fresh troops could be brought up and the artillery could be placed in position, another move forward was initiated. A preliminary attack on 27 September by American troops on the Guillemont farm position (from which the Germans had not been dislodged) did not succeed, but the failure was drowned in the great roar of the British bombardment along the whole front, which opened on that day and was maintained for forty-eight hours. Had the American action of the 27th been a success, the more serious failure by those same troops on the 29th might have been avoided, and the Hindenburg Line might have been ruptured more quickly and with far greater loss to the enemy. There was, however, no time to reconsider plans for the improvement of the short American front, or to stop the vast machinery which had been set in motion. After two days' bombardment three British armies (and south of them the French) were launched in simultaneous attack.

To the north of St. Quentin it was planned that the Australians should push through on the heels of an initial attack by the 27th and 30th American divisions (attached to the Australian corps). The American advance melted away, partly by reason of having first to carry some German machine-gun defences near Guillemont Farm before it could reach its opening artillery barrage, partly through the inexperience of these raw troops in the work of 'mopping-up' German posts as the advance progressed. By the middle of the forenoon, when the 5th and 3rd Australian divisions were preparing to push through and continue the assault, they found that the American attack had been broken up and that the work was all to be done again from the outset, and without artillery barrage. Thanks to the resolute fashion in which the British 46th division, on the right of the Americans, swam the canal in life-belts, scrambled up the brick wall on the other bank, and drove into the enemy's position, the 5th Australian division (or at any rate its right wing) made good that side of the attack; but the advance of the 3rd division towards the canal tunnel and Le Catelet became much confused. Throughout the 30th the direction of the attack swung perforce from eastward to north-eastward, in response to German resistance about Bony village, but by the evening of 1 October hard infantry fighting had broken the back of the resistance, and the 5th division was pounding at the last of the German trenches, the Beaurevoir line. On the 3rd the 2nd division took over charge of the Australian line (all the Allied front was now steadily diminishing in length), and opened the last stage of the battle. The 5th and 7th brigades broke through the German defences, and the 6th brigade completed the work by pushing forward along the high road to Le Cateau and capturing German defences about the village of Montbrehain. On the evening of the 5th the 2nd Australian division was relieved in the line, and withdrawn to join the other divisions which had preceded it into rest areas.

The Australian corps saw no more fighting. After nearly a month in rest it was, in early November, on the march towards the front again when, after the battle of Landrecies, came the news that the enemy was asking for an armistice. But some Australian field artillery took part with the British in the last fighting; there were Australian tunnellers in the advance-guard of the British Fifth army east of Lille, moving towards Mons; and overhead the two Australian squadrons of fighting scouts fulfilled to the last their share of the work of hunting down German airmen. During October some of the biggest air battles of the war were fought over Tournai and Courtrai, in the final effort of the German air service to prevent British and Australian scouts from harassing the retreat.

The corps wintered about Charleroi, and in the spring of 1919 was gradually withdrawn from France, demobilized in England, and its soldiers repatriated to Australia. Of the A.I.F. only No. 4 flying squadron found place in the limited British army of occupation on the Rhine. It spent some two and a half months at Cologne.

The Light Horse.—The campaign in Sinai and Palestine began with some minor operations in the desert just east of the canal by Australian and New Zealand mounted troops in the spring of 1916. Hitherto the task of General Maxwell (commanding in Egypt) had been to defend the canal zone. The instructions to General Murray, who succeeded Maxwell early in 1916, went further; he was to attempt the re-conquest of the Sinai peninsula. In the summer Murray's troops held Romani in force, with outposts at various hods (palm-groves, marking wells) to the east of that place. Here early in August he was beset by a force of 18,000 Turks under Kress von Kressenstein, who, having driven in or captured the outposts, attacked the Romani position in force on 3 August. The Australian light horse gallantly withstood the brunt of this attack on the southern flank, unassisted by reserves until the enemy should commit his full strength. Time was vital, for the Turks were fighting for water as well as for victory. By the end of the day the enemy had done his worst, and a counter-attack of the New Zealand mounted rifles and light horse reserves drove back the wearied assailants, with over half their force either casualties or prisoners, first to Katia and then upon El Arish. There was no further serious fighting in the Sinai desert; need for establishment of sure communications rather than the enemy's resistance delayed Murray's entry into El Arish until 20 December. On the 23rd the Anzac mounted division marched on an enemy force at Magdhaba, on the right flank, and after a battle lasting all day stormed the Turkish position at dusk. The same division repeated this exploit on 9 January 1917 by the capture of Rafa in similar circumstances; in each instance a stout resistance was overcome only at the last moment, and by a general charge; and the issue at the end of the day—as with the Turks at Romani—was not merely the success of the attack but the procuring of water for men and horses. Murray's army was now at the entrance to Palestine, secured from any molestation on the desert flank, and encouraged by the knowledge that Arab tribes under the Sherif of Mecca had revolted from their Turkish masters. Across the desert had been laid a road of wire-netting, and the building of a railway from Kantara by Egyptian labour had been begun. Murray, having assembled his forces at El Arish, launched on 26 March an attack on Gaza which very nearly succeeded. The mounted troops fought their way round the enemy's land-

ward flank, attacked the Gaza position from the east and north, entered the outskirts of the town itself, and captured a Turkish divisional commander; but on the south of Gaza the infantry attack was held up, and, in the face of approaching enemy relieving columns, the disappointed Australians and New Zealanders on the north had to be withdrawn from the very threshold of victory. It was said afterwards that the commander of the Turkish garrison in Gaza had prepared to surrender, and accounted it a merciful dispensation of Allah that his enemy voluntarily disappeared. On 17 April a second attack on Gaza failed signally, and thereafter the British sat down in trenches before the enemy to prepare for a regular campaign. Murray was replaced in command by General Allenby from France; the army was considerably increased in infantry and artillery strength (even tanks were added to it); and it was decided that for the successful operations of this augmented force the completion of the railway across the desert from Kantara was essential. The whole summer and early autumn of 1917 were spent in this laborious undertaking, and in October the railway had reached Allenby's front, and a water-pipe line had wormed with it across the waste of sand-dunes.

Beersheba.—Meanwhile the enemy had been working with equal industry. The Gaza defences were strengthened and prolonged in a regular fortified system as far as Beersheba (a front of twenty miles); and German engineers were completing with all haste an extension of the Turkish Palestine railway from Nazareth and Jerusalem to serve the Gaza line. By the time Allenby was ready, the Gaza-Beersheba position was from the front almost impregnable, and was defended by a Turco-German army of about 200,000. The situation indicated an attack in flank—which involved a considerable extension of the line of assault. Allenby's plan was that the XXI corps should engage the defenders of Gaza and the XX corps those of Beersheba, while the Desert Mounted corps under Chauvel swept round the enemy's left flank to attack Beersheba from the east and north. Upon success at Beersheba depended the whole battle. Chauvel's force started out in the night of 27 October on a wide detour through oases of the eastern desert, and three evenings later had turned and was marching on its real objective. At dawn on 31 October, while two divisions of infantry opened the frontal attack on Beersheba, the Australian and New Zealand horsemen (with British yeomanry in reserve) went into action against Turkish positions in the hills near the Hebron road behind the town. Their efforts through most of the day were devoted to reducing the strong defences on Tel-el-Saba hill, but these resisted stubbornly until mid-afternoon, the day was wearing out, and still the main task remained to be performed. At 4 p.m. Chauvel, instructed that further delay would be fatal, ordered the 4th light horse brigade to charge the Beersheba eastern defences. The order committed the brigade to a two-mile gallop under shrapnel against trenches of unknown quality, which had not been reconnoitred. With the utmost eagerness the 4th and 12th light horse regiments dashed at the enemy. The troopers carried neither sword nor lance; they rode with bayonets fixed to rifles, or bayonets bare in their hands. At eight hundred yards from the enemy they came under heavy machine-gun and rifle fire, but undaunted—and unconsciously establishing a precedent for mounted action in this campaign—they galloped unswervingly at the double line of trenches now disclosed ahead of them. Fortunately these earthworks were not wired. The horsemen took the obstacles (one of them ten feet deep and four feet wide) in their stride, threw themselves from their horses, and leapt into a hand-to-hand contest with the defending infantry. Meanwhile the remainder of the Anzac mounted division came up in a cheering rush and swept into Beersheba town, and the troopers of the 4th brigade, having killed, captured, or put to flight the defenders of the trench system, joined their comrades in Beersheba. The enemy soon abandoned the attempt to fight. Infantry, gunners, and transport drivers fled in rout through the streets, and the Turkish position was definitely turned. Meanwhile the XXI corps had begun its attack on Gaza with the capture of the important Umbrella Hill. During the ensuing days the XX corps and the cavalry continued the rolling up of the enemy's left flank, and on 6 November captured Sharia, in the centre of the defenders' line. That same night the Turks evacuated Gaza, abandoning great quantities of stores, and next morning the pursuit began up the floor of Palestine. The cavalry, assisted by the air force, hustled the rear-guards relentlessly; valuable supply stores, ammunition dumps, and aircraft equipment were seized at Et Tine and other places. Ramleh, Ludd, and Jaffa were occupied by the cavalry advance-guards, and on 19 November the advance threatened Jerusalem. The Holy City was spared a projected attack by the Turks' withdrawal on the night of 7 December. The retreat came to a standstill in the hills south of Nablus, and here trench-warfare was gradually resumed. A Turkish attempt to recapture Jerusalem on 27 December failed; it was merely the precursor of a renewed advance on this flank, and after some successful minor operations the Anzac mounted division and two infantry divisions pushed out on 19 February 1918, captured Jericho, and reached the Jordan.

The Jordan Valley.—Meanwhile the Arab rising along the desert railway beyond the Dead Sea was causing the enemy serious concern, and Allenby's policy was to encourage these auxiliaries and endeavour to effect a junction with them beyond the Jordan. In order to hamper the Turks about Maan, whom the Arabs were seeking to envelop, Allenby decided to despatch a strong raiding force across the Jordan to seize Amman and destroy at that place a viaduct on the railway line. This force—consisting of an infantry division, the Anzac mounted division, the camel brigade, and artillery armoured cars—crossed the Jordan on 23 March after some opposition, and pushed north on Es Salt and east on Amman. Es Salt was occupied two days later, and on the 26th and 27th the Australians and New Zealanders attacked the railway south of Amman. A section of the line was destroyed, but the demolition parties failed to reach the viaduct. A mounted attack on Amman town on the 27th met with strong opposition, and a general attack assisted by the infantry next day also failed. Hot fighting continued here until the 30th, when the arrival on the Jordan and at Amman of Turkish reinforcements obliged the raiding force to break off the attempt. The retirement was skilfully carried out, and by 2 April the whole force had re-crossed the Jordan, leaving a garrison on the farther side to hold a naturally strong bridge head at Ghoraniyeh. On 30 April a second raid was made across the Jordan with the object of capturing the Shunet

Nimrin position, which the Turks had meanwhile considerably fortified. While the 60th division prepared to attack this place in front, the Australian mounted division moved by night against Es Salt and occupied that town in the evening of the 30th. The Turks, however, were more prompt than previously with counter-measures. A cavalry division and some infantry were hurriedly thrown across the Jordan at the Jisr-ed-Damie ford, west of Es Salt; and the light horse, thus heavily attacked in flank, found their attention much distracted from their pre-arranged task, which was to turn the Shunet Nimrin position from the north. After several days' severe fighting in defence of the road of retreat by Umm-es-Shert, the light horse at Es Salt were obliged to retire while there was yet time, and the attack on Shunet Nimrin was abandoned.

The Great Ride.—For some months Allenby's plans for further offensive operations were held in abeyance. Summer in the Jordan valley descended with all its severity on the army in that region, and all British troops that could be spared from Palestine were ordered off to France to reinforce the stricken line on the Western front. An attack in force by German troops along both sides of the Jordan on 14 July succeeded temporarily in capturing the important hill of Abu Tellul, but a prompt counter-attack by the 1st light horse brigade recovered it. Meanwhile, the withdrawals of British cavalry and infantry (amounting to nearly four divisions) from Allenby's army were made good by the arrival of Indian cavalry and infantry, two Jewish battalions, some Armenians and Algerians, and coloured troops from the British West Indies and South Africa. It was an army of mixed races and colours which Allenby finally launched in attack against the Nablus position on 19 September. The features of this famous battle, fought (in part) on the plain of Armageddon, are well known. The German command was deceived partly by its experience of the raids on Amman and Es Salt, partly by the skill of Allenby's preparations, into thinking that the attack would come by way of the Jordan flank rather than on the Mediterranean side—where the defences were perhaps stronger, where there was little ground for manoeuvring, and where help from the Arab tribes would not be available. An important factor in the British surprise was the work of the air force, in which the star squadron was No. 1 squadron of the Australian flying corps. Allenby's concentration on his left wing could scarcely have been concealed from enemy observation—in spite of the dummy camps and pretended activity on the Jordan side—if that enemy had been able to conduct the usual reconnaissances by air. But during most of August and all September air reconnaissance was denied to the German airmen; as soon as they appeared, the British (and notably the Australian) airmen attacked them and drove them off, generally destroying them in air combat. There was no air work so entirely effective done at any other time or on any other front during the war. When on 19 September Allenby's infantry broke through the Turkish lines on the coast with a massed attack, and the cavalry immediately started on its famous ride round the enemy's rear, the surprise of the Germans was complete. The ride was entrusted to the Desert Mounted corps under Chauvel, and in it participated the whole of Allenby's mounted force (12,000 strong) with the exception of the Anzac mounted division, which remained on the Jordan. On the morning of the 20th the Indian cavalry entered Nazareth, to the consternation of the German supply service; the Australian mounted division was in Jenin, and rolling up what was left of the Turkish flank in the hills north of Nablus. During the next few days Beisan and other points in the Turkish rear were seized, and the fate of the Turkish 7th and 8th armies, still at Nablus, was sealed beyond doubt. When the news of this shattering blow reached the headquarters of those armies, their retreat speedily became a rout. The only road left open for their retirement was north-east from Nablus by way of the precipitous valley of the Wadi Fara, and in the general direction of Deraa Junction (north of Amman) on the desert railway. In the defiles of the Wadi Fara columns of Turkish transport, artillery, and marching troops were butchered under bombing attacks of the British airmen, and the greater part of this work was done by No. 1 Australian squadron. By the end of the month the Turkish 7th and 8th armies had ceased to exist; their entire force, with negligible exceptions, had been either killed or captured. Meanwhile news of the disaster spread to the Turkish 4th army, east of Jordan. At the first sign of alarm on that side the Anzac mounted division under Chaytor and the few infantry battalions left to hold that flank with it, crossed the river and began the advance on Amman, which was captured on 25 September. There was little enemy resistance; the local Turkish and German forces concentrated solely on flight towards Deraa (already closed to them), and upon these fugitives, too, was visited near Mafrak the fury of No. 1 squadron's air attacks. On 29 September a Turkish corps, marching along the railway northward from Maan, surrendered near Amman to Chaytor.

Chauvel's cavalry, having concentrated about the Lake of Tiberias, was now in rapid movement towards Damascus, and so were the Arab tribes on the desert side, each striving as much for the honour of being first in the Syrian city as for the rounding up of the handful of Turkish fugitives who were making northward from Deraa. Chauvel had to fight determined rear-guards (chiefly German machine-gunners) at Jisr Benat Yakub and at Saza on the way up to Damascus. On 30 September the light horse passed aside from Damascus to cut off the enemy's retreat north-west by way of the Abana gorge; having succeeded in that enterprise and captured 4000 more prisoners, they sent the 5th light horse brigade into Damascus in the early morning of 1 October. Fighting was now at an end, and October was spent chiefly in the hurried pursuit of a few thousand Turks through Beyrout, Homs, and Hama to Aleppo, which was reached by the armoured cars on the 23rd. The Turkish armistice was signed on 31 October 1918, and its terms involved the unconditional surrender of Turkey.

Detached Work.—To complete the record of the A.I.F.'s many theatres of action during the war, mention must be made of the Australian wireless signal squadron (120 officers and other ranks) which joined the British force in Mesopotamia at the end of 1916, and served with it until the end; of the small party of selected Australian officers and men from France who in July 1918 joined the British North Russian Expeditionary Force for the defence of Archangel and the Murman coast; and of the volunteers with General Dunsterville's force in Caucasia in 1918. The Caucasian operations were remarkably adventurous. One hundred officers and 250 sergeants were selected from the

army in France for special duty in training Persian and other local levies for operations near the Caspian Sea; and of these 18 officers and 20 sergeants were from the A.I.F. During August and part of September Dunsterville's force made a spirited defence of Baku against strong Turkish attacks—the object of the expedition to Baku was to save the oil wells—but finally was forced to withdraw, owing to lack of expected aid from the local populace. Dunsterville's operations, however, saved northern Persia from a threatened Turkish invasion.

The repatriation of the men of the A.I.F. from England and Egypt went on during most of 1919 and 1920. Many of them were sick, wounded, or permanently incapacitated, and continued in Australia to be patients in military hospitals. While they and the hospitals remained under the control of the defence department, the A.I.F. had not quite ceased to exist. The last formal action which converted these men into civilians, and the hospitals into civilian hospitals, was taken on 1 April 1921. On that date the Australian Imperial Force passed finally into history.

A.I.F. Badge.—It should be noted that the badge of the A.I.F., often called the Rising Sun, has really no connection with that object. It originated as a badge for a regiment of light horse that was the first Federal contingent to serve in the South African war, and was designed to imitate roughly a trophy of arms (swords and bayonets surrounding an imperial crown) in the possession of Sir Edward Hutton, who then commanded the Commonwealth military forces. In 1903 a Birmingham firm, asked to design a badge for the whole of the Commonwealth forces, adopted this light horse badge and, not knowing its origin, deviated still further from the trophy pattern. This design was at first worn only by staff officers, but on the introduction of universal training came into general use, and was naturally adopted in 1914 by General Bridges for the distinguishing badge of the A.I.F.

Battle Honours.—In allotting battle honours to any unit of the military forces it is required that headquarters and at least half the strength of the unit shall have been present at the engagement. Under these conditions Australian units may be allowed to emblazon on their colours one or more (up to ten) of the following:—

A.N. & M.E.F.: Herbertshohe (properly Kabakaul, as there was no fighting near Herbertshohe).

A.I.F.: (1) on Gallipoli: Landing at Anzac, Defence of Anzac, The Chessboard, Quinn's Post, Lone Pine, Russell's Top, Hill 60.

(2) on the Western Front: Fromelles, Pozières, Mouquet Farm, Retreat to Hindenburg Line, Bullecourt, Lagnicourt, Messines, Menin-Road Ridge, Polygon Wood, Broodseinde, Passchendaele, Ancre, Villers-Bretonneux, Hamel, Hazebrouck, Meteren, Amiens, Chuignes, Mont St. Quentin, Havrincourt, Epehy, St. Quentin Canal, Beaurevoir.

(3) in Egypt and Palestine: Senussi operations, Romani, Gaza, Jerusalem, Jericho, passage of Jordan, Jordan Valley operations, Tel Asur, Megiddo, Damascus.

The actual allotment is still in progress (1925). F.M.C.

Australian Salmon, a percoid fish of the genus *Arripis;* its exact affinities are somewhat uncertain. There are two species, *A. trutta* (Sea Salmon) and *A. georgianus,* both occurring in the

Sea Salmon.

temperate and cooler waters of Australia, and moving in vast shoals along the coasts. Though commonly known as 'salmon,' they have neither resemblance to nor affinity with the true Salmonidae, although the young are ornamented with markings somewhat similar to those of trout, and are therefore—equally incorrectly—known as salmon trout. Though not regarded as of much value as food-fishes in Australian markets, these salmon are sold in considerable quantities by fish-hawkers. At Lord Howe Island they grow large and fat, and are excellent eating when baked. Large specimens (20-30 inches long) afford excellent sport to anglers, leaping clear of the water and fighting valiantly for their freedom when hooked. *A. georgianus* is common in the southern markets, and is known as 'roughy' in Melbourne and 'tommy rough' in Adelaide; but it must not be confused with the New South Wales 'roughy,' which is *Trachichthys australis,* a distant relative of the nannygai. A.R.McC.

Australind, a small township of Western Australia situated on Leschenault Inlet seven miles north of Bunbury, the relic of an ambitious colonization scheme put forward in 1839 by the Western Australian Company (not to be confused with the Western Australian Association). The early colonization of Western Australia (q.v.) involved a series of misadventures. The great difficulty was the lack of labour, convicts being excluded and free immigrants being almost unobtainable for lack of funds to bring them out, while the large grants of land made to the first settlers involved the scattering of the community over a very considerable area. After much unsuccessful negotiation with the British government, the Western Australian Company was formally constituted in 1840, and decided to buy land from a private owner and sell it to small farmers from a plan available in London. The area selected was a grant originally made to a Colonel Lautour near the mouth of the Collie River on Leschenault Inlet in Geographe Bay, where there was already a whaling station and a depot for breeding horses for India. After some delay—caused partly by a report that Lautour's grant had been resumed by the colonial government, partly by George

Grey's adverse opinion of the Leschenault district and desire to get the settlement shifted to the neighbourhood of Geraldton—the ship *Parkfield* in March 1841 brought out the first batch of settlers, and found herself anchored near 23 American whalers. The town of Australind, a magnificent conception intended to cover 1000 acres—besides the reserves for public buildings, churches, hospitals, colleges, pleasure-grounds, quays, markets and cemeteries—was already laid out; but the 100-acre 'rural' allotments, on the clearing and cultivation of which the whole scheme depended, were still bush, and remained bush for many years. Labour was no more easily found by this scheme than by any other; the emigrant labourers for whom a free passage was provided preferred to go to the eastern colonies, and the settlers who had purchased land, expecting to live in the town and get their farms cultivated by hired labour, found themselves compelled to do their own work or starve, though they were, as a rule, unfit to do farm work even under English conditions. In 1843 the scheme collapsed, and Australind decayed, its one sound asset—the safe harbour—being exploited more satisfactorily by the newer settlement of Bunbury at the mouth of the Inlet. Not till 1875, however, was it decided to wind up the company, and the final proceedings took several years to complete.

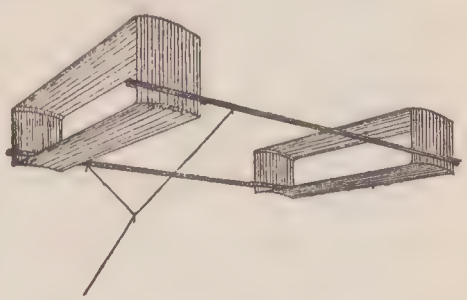
See *Western Australia and the Settlement at Australind*, published by Smith, Elder & Co. in 1842.

J.S.B.

Aviation. In March 1851 Dr. William Bland (q.v.) designed an 'atmotic ship,' drawings of which he sent to England for the Great Exhibition of that year; they arrived too late, but a model of the machine was shown in 1852 at the Crystal Palace. This 'ship' consisted of an elongated balloon, capable of lifting five tons, with an attached car containing a steam-engine actuating two screws by which the ship could be driven against the wind. As the weight of the car when fully loaded with fuel was 3½ tons, there was theoretically a surplus lifting power of 1½ tons available for passengers, etc. Bland's estimate of the possible speed was only 50 miles per hour, but he was sanguine enough to prognosticate the reduction of the passage between England and Australia to four or five days. In 1866 he announced his invention to the world in a broadsheet, but it attracted little notice, and his death in 1868 cancelled its last chance of being tried.

In 1878 Lawrence Hargrave (q.v.) began to study the movements of birds, fishes, and insects, and was impressed by the fact that fishes in diving turned aside and twisted their tails in a certain curve. Investigating still lower forms of animal life, he found in the worm three motions essential for flight—(1) starting and stopping while on a direct route, (2) turning to right or left, (3) rising vertically. He therefore constructed a large wooden model of a worm, and by means of radial wires attached to fixed points, recorded the curves along which these points travelled during the motion of the whole model. From these records, which showed the curves to be trochoids, he prepared an address on 'The Trochoided Plane,' and on 6 August 1884 delivered it before the Royal Society of New South Wales—the first public announcement of the possibility of achieving artificial flight. 'In its first stages' he said, 'the motion will be slow; and, as we gain confidence in the construction of the machine, we shall notice that by leaning our bodies in the direction we wish to go . . . . and reducing the speed of the planes, our object will be attained.' In 1885 he described to the Royal Society the flight of a plane built of paper and thin cane, with undulating wings, which when propelled by the contraction of rubber bands flew for 98 feet. In the following 15 years he read 19 more papers, illustrated by models.

In Australia little notice was taken of him or his discoveries. As late as 1898, when Langley in Canada was experimenting with planes, Hargrave told the Royal Society of New South Wales 'It appears regrettable that Australians should leave to Americans and others the tardy adoption of views circulated by this Society.' Among the few who recognized his genius was Richard Threlfall, then professor of physics at the university of Sydney, who said openly that Sydney would one day be famous 'not so much for its beautiful harbour as for the fact that it had been the home of Lawrence Hargrave, the inventor of human flight.' Outside Australia more attention was paid to him, and in 1900 Wilbur Wright asked permission to use his patents, only to be told by Hargrave that he took out no patents and wished the Wrights every success in applying his discoveries. These by that time covered the utilization of flat and curved horizontal planes, and straight vertical planes as used in the making of the box-kite that bears his name; in 1903 the Wrights, by applying these principles to larger box-kites, solved the problem of human flight.



A Hargrave Box-kite.

The Hargrave box-kite was also adopted, in 1906, by Santos Dumont for the first European flight, and in 1908 by the makers of the Voisin and Farman aeroplanes.

Hargrave also devised and constructed model engines, some with revolving cylinders carried on the propeller blades; from these were developed the engines of the Bleriot monoplane that first flew the English Channel, and the famous Gnome rotary engine.

Only in 1908 did Australia awake to the importance of aviation. In that year Farman in January flew nearly 1 mile in Paris. In March he flew 2½ miles. In May the brothers Wright in America, who five years previously had been the first in the air, flew 6 miles. In June Delagrange in Italy flew 10 miles; in July Farman flew 11 miles; in September the Wrights flew 56 miles, and in December 61 miles—the rapid increase in distance showing the remarkable development of aviation in a single year. In March 1909, after Zeppelin in Germany had cruised 150 miles, with 25 passengers, in his dirigible balloon, the world awoke to the possibilities of aviation for military purposes, and

the greater nations began to hasten improvements in aerial machines. Australia joined in the general enthusiasm, particularly when it was pointed out that the successful aeroplanes were based upon Australian discoveries. To arouse the public to the importance of aviation for national defence in such a wide and undefended area, an Aerial League was formed in New South Wales on 28 April 1909, with branches in Victoria and Queensland. By means of public meetings the league secured the attention of the federal government, and a prize of £5000 was offered (provided that another £5000 was subscribed by the public) for the first Australian-made aeroplane that fulfilled certain conditions. When it was found that the public did not subscribe adequately, the federal government allowed its prize of £5000 to stand, and the military authorities were requested to draw up conditions; but as these stipulated that to win the prize an aeroplane must 'hover' no entries were forthcoming. The writer of this article (who had been one of the founders of the Aerial League) was, however, invited to join the intelligence corps of the Australian army, which comprised experts in many subjects of military value; and with the encouragement of the corps, and of the United Service Institution of New South Wales, interesting experiments in aviation and wireless were undertaken. One of particular value was the study by the writer of air resistance on curved planes, with the construction of a biplane 28 feet long and weighing 102lb., with planes 4 feet 6 inches wide which were curved in a degree that would enable flight against any wind over 10 miles an hour—the minimum force required for uplift. Experiments were carried out at Narrabeen beach, some miles north-east of Sydney, the writer thus being the first man in Australia to rise in the air on a free heavier-than-air apparatus. This was also the first occasion on which a motorless aeroplane was utilized for direct flight, a principle not taken seriously in Europe until 1922. The machine had a box-kite as tail balance, and steering was performed by the leaning of the operator from side to side; it was demonstrated that flying against the wind, turning and gliding back to above starting point, turning again to fly against the wind, and continuing in the air while the wind lasted, were all possible. Twenty-nine successful flights were made on 5 December 1909.

In the same month the first imported aeroplane reached Australia; this, a Wright machine, was exhibited in the various States, but no flights were undertaken. Early in 1910 H. Houdini brought a Voisin aeroplane to Australia, and made his first flight at Diggers' Rest in Victoria; successful flights were also made at Rosehill, near Sydney. About the same time a young experimenter, J. R. Duigan, constructed an aeroplane and machine near Mia Mia in Victoria, and on 16 July 1910 made a hop of 24 feet, and in September a flight of 100 yards. In the same year a Bleriot machine arrived in Australia, and a few short flights were made with it by Cuthbert of Adelaide. Early in 1911 arrived a Bristol aeroplane, which was flown by J. Hammond; one flight of particular interest was that from Mascot near Sydney to Liverpool, a distance of 18 miles, on 3 May. This machine was later transferred to W. E. Hart, who among other interesting flights made one of 30 miles from Penrith to the agricultural showground at Sydney. On 15 April 1912 Alban J. Roberts exhibited at Sydney an elongated balloon eight feet long, which was directed and controlled by wireless waves.

About this time an Australian airman, Harry G. Hawker, became prominent in English flying circles. Born in Victoria on 22 January 1889, he joined the Sopwith training school in England in 1912, and on 31 May 1913 established a height record of 11,450 feet, which in June he increased to 13,400 feet. In August of that year, during an attempt to fly completely round the British coasts, he covered 1043 miles in a seaplane in 55¾ hours. In the early months of 1914 he did some flying in Australia, but returned to England in June, and during the war acted as test pilot for the Sopwith firm, on 6 June 1915 achieving a height record of 18,339 feet. In May 1919 he attempted to cross the Atlantic from Newfoundland, but failed after flying over 1000 miles; on 16 July 1921 he was killed at Hendon while competing in the 'aerial Derby.'

During the war Australian work in aviation and air-plane construction was mainly carried on in Europe and at the various Eastern fronts. The record of flight achievements in Australian contingents has been chronicled in F. M. Cutlack's *Australian Flying Corps* (vol. viii of the Official War Histories); but several Australian airmen served in British corps and made names there. It is recorded, for instance, that Captain Brian Dowling, R.F.C., when piloting a machine over the German lines, had his steering gear and right wing shot away by anti-aircraft guns; the machine side-slipped and was about to crash when Dowling asked his observer to climb out on the left wing, then almost perpendicular, and his weight in this perilous position brought the machine back so near to normal level that Dowling was able to steer it back to the British lines. The history of the Australian Flying Corps may be summarized here very shortly. Its first section took part in the Baghdad expedition of 1915, and those who were not killed were made prisoners by the Turks in Kut; the first complete squadron served during 1916-8 in Egypt and Palestine; three other squadrons were trained in England and served on the western front in 1917-8. The four squadrons comprised 410 pilots, 153 observers and 40 other officers: of these 78 were killed, 68 wounded, and 33 taken prisoner. Of their machines 60 were destroyed by enemy action and 13 otherwise: on the other hand, they destroyed 276 enemy machines and drove down 251. On 31 January 1919 the number of flying officers was—wing commanders, 2; squadron commanders, 9; flight commanders, 27; junior flying officers, 386; under instruction, 52.

While demobilization was proceeding, the Commonwealth government offered a prize of £10,000 to the first Australian airman who made the flight from England to Australia within 30 days. Six parties made the attempt, but only two got through. The prize-winning flight, that of Ross and Keith Smith, is described under Smith, Sir Ross. A second party—Lieutenants R. J. P. Parer and J. C. McIntosh—completed the flight after long delays: they started from England on 8 January 1920 but reached Port Darwin only on 2 August, mainly because (as they had been warned before starting) the engine-power of their air-plane was inadequate. As a feat of courage and endurance their flight is notable, but its value to students of international aeronautics was limited. A third flight from Europe to Australia, undertaken in April-

May 1925 by an Italian airman, Major Francesco de Pinedo, used several deviations from the earlier route. Starting from Brindisi on 27 April de Pinedo flew by Leros in the Aegean Sea to Baghdad, thence to Basra, Karachi, and Bombay by the usual airway; crossing India direct to Cocanada in the Godavery delta, he visited Calcutta, Akyab, Rangoon and Penang on the way to Singapore, and made thence by Batavia, Bima in Sumbawa, and Kupang in Timor, to Broome in Western Australia. The total distance, about 10,500 miles, was covered in 35 days from Brindisi.

With the advent of peace in 1919 and the return of Australian airmen to their own country, aviation came slowly into use for the transport of mails, goods and passengers across the vast Australian continent. In December 1920 an air navigation act was passed and a civil aviation department established under Lieutenant-colonel H. C. Brinsmead as controller. The first aerial route (1200 miles) was established on 6 April 1922 between Derby and Geraldton in Western Australia; it was extended to Perth in 1924, and weekly mails, and passengers, are now carried with regularity. The route is subsidized to the extent of £30,000 per annum. On 2 November 1922 a route was established from Charleville in western Queensland to Cloncurry (560 miles), with a subsidy of £12,000; this route was extended in February 1925 to Camooweal on the border, 248 miles farther away. Aerial services between Adelaide and Sydney and between Sydney and Brisbane were contracted for in 1921. The Adelaide-Sydney service was started on 2 June 1924; but in the early months of 1925 it was decided to abandon this service and substitute services from Adelaide to Cootamundra *via* Mildura and Hay, with branches from Mildura to Broken Hill and from Hay to Melbourne. The subsidy is 4d. per mile flown. On the routes in operation at the end of 1924 there are 59 landing-grounds, and 28 more have been provided elsewhere. Routes have been surveyed from Melbourne to Perth, from Adelaide to Port Lincoln, from Melbourne to Hay, and from Derby to Wyndham, but on these routes no landing-grounds exist as yet. A military route has been surveyed from Cloncurry in Queensland to Port Darwin. Contemplated, but not yet surveyed, routes include those from Oodnadatta in South Australia to Alice Springs in the Northern Territory, from Brisbane to Charleville, and from Townsville in northern Queensland to Rabaul in New Britain. Up to the end of September 1924 the figures for the three existing services were as follows:—flights 3414, miles flown 494,978, passengers carried 2741, letters carried (to end of August) 349,153, freight carried 20,076 lb. Postage rates on all services are 3d. per half-ounce in addition to ordinary postage.

In April-May 1924 Wing-commander Goble and Flying-officer McIntyre in a three-year-old Airey seaplane flew round the whole of the Australian coast, covering 8568 miles in 44 days (90 flying hours). Their object was to make a rapid survey of the coast in order to select the best sites for coast-defence air-stations: they had no prepared aerodromes or repair bases, and no information about local conditions, meteorological or other, except what they could pick up on the way. It was one of the finest flights in the history of aviation, and the Royal Aero Club in 1925 awarded to its achievers the Britannia challenge trophy for the best flight of 1924.

Axe-breaker, See NOTELAEA.

Ayers, SIR HENRY (1821-1897), born at Portsea in England on 1 May 1821, and trained for the law, in 1840 migrated to South Australia to follow his profession, but in 1845 became secretary of a company formed to work the Burra Burra copper mines. In March 1857 he was elected to the legislative council. For 11 days in July 1863 he was a member of the Dutton ministry, and upon its resignation formed his own first cabinet, which lasted (with a few internal changes) until August 1864; he then became chief secretary in the first Blyth ministry, held the same portfolio in the second Dutton ministry, and in September 1865 once more took the premiership, but held office for only a month. Between 1867 and 1873 he was premier and chief secretary in four other ministries, and chief secretary in the Colton administration from June 1876 to October 1877. In June 1881 he was elected president of the legislative council, and held that position until his retirement in 1893. While he was premier in 1872, the overland telegraph line was opened for traffic. For 40 years he was a trustee of the Savings Bank of South Australia, and for many years chairman of the board. For 35 years he was governor of the Botanic Gardens board. He was also first president of the Old Colonists' Association, and treasurer of the university council. As an administrator and organizer his reputation stands high; his strong prejudices against borrowing often restricted the extension of the national debt, and to his foresight, penetration and commercial courage many flourishing businesses owe their success. As a representative of South Australia at intercolonial conferences he was a prominent figure. In 1863 he represented the State for the consideration of uniform tariffs and custom duties, and their distribution, in 1864 for the conference in Melbourne dealing with the transportation of criminals from the United Kingdom; in 1867 for the meeting of delegates in Melbourne to consider the ocean postal question; and in 1873 and 1877 he was again chosen to represent South Australia in intercolonial conferences in Sydney. He died on 11 June 1897. (C.M.G., 1870; K.C.M.G., 1872; G.C.M.G., 1894.)

B

Babblers, (*a*) a general term used for the Timaliidae. The typical genus, *Timalia*, is found in the Malay islands, one species reaching Bengal. Some other forms that are commonly included in the Timaliidae may be related to *Timalia*, but the 'family' with the limits usually assigned to it has long been recognized as artificial; Sharpe calls it 'the rubbish heap,' and a German distich runs:—

Was man nicht unterbringen kann,
Sieht man als Timeliden an.

(Birds that cannot be otherwise classified are considered to be Timaliidae).

Among Australian birds still allotted to it by some authorities are the coachwhip-birds, field-

Australian Babbler.

wrens, ground-wrens, ground-birds, log-runners, pilot-birds, scrub-robins and song-larks, all of which are separately dealt with.

(*b*) In Australia the name is restricted to birds of the genus *Pomatostomus*, belonging to the family Crateropodidae distributed throughout tropical Asia, the Malay Archipelago and Australia. This family contains a portion of the birds formerly grouped as Timaliidae, characterized by their stout, somewhat curved bills and strong legs and feet. Four species of *Pomatostomus* occur in Australia, none of them extending to Tasmania. The commonest in south-eastern Australia is the Australian Babbler (*P. temporalis*); the most widely distributed is the White-browed Babbler (*P. superciliosus*), found throughout the continent.

In habits all the species resemble one another. They are about the size of thrushes. In coloration they are brown above and white on the underparts, with white eyebrows and white tips to the tail-feathers. They are sociable, live in small parties, and are generally found in open forest country inland; they are noisy and garrulous, commonly feeding on the ground; when alarmed they take to the trees, which they ascend one after another in a series of hops, at intervals stopping to peer down and utter their chattering call.

Their nests are large and solidly built structures of twigs, with a passage-like entrance at one side, placed a few feet from the ground in a bush or small tree. A large number of nests are constructed, but only a few appear to be completed with the lining of grasses; the rest are apparently abandoned. The four eggs are light brown or greyish, blotched with purple and brown, and streaked with fine black lines.

Backhaus, Henry (1811-1882), born at Paderborn in Westphalia, was trained at Propaganda, Rome, where he was ordained priest in 1836. For some years he served as chaplain to the French troops in India, and came later to Adelaide. At the close of 1851 gold was discovered at Bendigo, and people flocked there from all parts of Australia. Father Backhaus determined to accompany his flock, and in 1852 celebrated Mass for the miners in a calico tent at Bendigo, which he soon replaced by a large church dedicated to St. Kilian. In laying the foundations for his own residence a rich gold deposit was discovered, for which he was offered £10,000. Wealth poured in upon him from the opulent gold-miners, and on his return to Germany it was said that he was wealthy enough to purchase a principality. At his death in September 1882 he bequeathed his property, valued at £250,000, to religious purposes in the Bendigo diocese.

E.M.O'B.

Backhouse, James (1794-1869), born at Darlington in England on 8 July 1794, studied botany and its practical applications in English and Scottish nurseries, and in 1822 bought the old nursery of the Telfords at York. He also about that time became a leading member of the Society of Friends. For some years he felt a strong call to visit the Australasian colonies; this seems to have been a purely personal impulse, though before leaving England he obtained credentials and letters signed by the congregation of Friends at York to which he belonged. On 3 September 1831 he and George Washington Walker (q.v) sailed from London on the first religious mission undertaken by Quakers in Australasia. They reached Hobart on 8 February 1832, and at once entered on their work, holding meetings and putting tracts and religious books into circulation. Colonel Arthur gave them every facility for their undertaking, and during the next three years they systematically visited every gaol, convict settlement and chain-gang in the island. It does not appear that their ministrations had any great or lasting effect at Macquarie Harbour or Port Arthur, or among the chain-gangs, but their genuine piety and love of humanity won them respect and a hearing everywhere. In April 1832 they took part in the founding, at Hobart, of the island's first temperance society, a thing much needed in a community where hard drinking was almost universal. Mostly on foot, with a Bible in one hand and a pocket compass in the other, they traversed almost all the settled districts from Pittwater to Circular Head and from Oyster Bay to Macquarie Plains,

and visited the remnant of the Tasmanian aborigines on Flinders Island. From Hobart they went to Sydney, and spent two years in similar work in New South Wales, visiting not only the settled districts of the colony but the 'ocean hell' of Norfolk Island and the penal settlement at Moreton Bay. Their subsequent reports on the convict system helped to promote reforms in penal methods and to improve the lot of the prisoners. They also supplied the government at Sydney with suggestions for the better care and treatment of the aborigines, as well as a report of a general nature, in which, amongst other things, they deprecated the licensing of breweries and distilleries. They returned to Tasmania in 1837 and seven months later went to Melbourne, from which infant settlement they passed on to South Australia and Western Australia. From Fremantle they sailed on 12 February 1838, for the Mauritius, and after a short stay there went to the Cape Colony, where they visited remote districts in the course of their work. Backhouse found time during his tour to make large botanical collections in Australia and Norfolk Island. In February 1841 Backhouse returned to England, and told the story of their nine years' work and wanderings in his *Narrative of a Visit to the Australian Colonies* (1843) and *Narrative of a Visit to Mauritius and South Africa* (1844). Walker returned to settle in Hobart but Backhouse devoted himself to missionary work in Great Britain, and died at York on 20 January 1869.

While there were already Quaker families (e.g. the Cottons) settled in Tasmania when Backhouse and Walker arrived, it is perhaps due to their influence—especially to that of Walker—that the Society of Friends finds in Tasmania its chief centre in Australasia.

Backhousia, a genus of the family Myrtaceae, chiefly found in eastern Australia, consisting of trees or shrubs with opposite feather-veined leaves. The calyx-tube is broadly bell-shaped, with petal-like lobes; petals 4, shorter than the calyx-lobes; stamens in several series; capsule enclosed in the calyx-tube, the seeds falling with the fruit. *B. citriodora* yields a lemon-scented oil like that extracted from the Lemon-scented Verbena (*Lippia citriodora*), whose perfume is used for scenting soaps. It has a fine, hard-grained timber used for ornamental work. *B. myrtifolia* (Scrub Myrtle) is an ornamental shrub or small tree with showy white flowers, having a tough, durable timber suitable for turnery. The genus is named after James Backhouse (q.v.).

Bacteriology, Economic. A purely Australian microbe has not yet been found, nor is it probable that one will be; several have been first discovered here, but all have afterwards been found in other countries. The microbe that produces gummosis of the sugar-cane is a case in point. In this disease the plants affected show symptoms of decay, and, when cut across, exude from the cut ends of the fibrillar strings a yellow gummy mass. Microscopic examination shows that the large rounded vessels of the vascular bundles are filled with gum, which by plugging up the vessels prevents the transmission of nourishment through the plant; if the main tubular vessels are choked, the whole plant is affected, otherwise only a part of it suffers. N. A. Cobb, who discovered that the gum always contains microbes (which he named *Bacillus vascularum*), was of the opinion that the microbes produced the gum. The truth of this is now undoubted, and the writer of this article has grown the microbe and produced the gum in his laboratory on a jelly containing sugar-cane juice. The artificial gum had all the properties of the natural gum, and was, in fact, identical with it. Further, E. F. Smith in America has, by inoculation with pure microbes isolated from diseased cane, reproduced the disease in healthy plants.

The production of gum by bacteria inhabiting the tissues of plants is of common occurrence in Australia. Wattle gum, for instance, is of two kinds; one is soluble in water and adhesive like gum acacia, the other simply swells when soaked in water. The latter consists of metarabin or cerasin, is found exuding from the trees in cold climates, and is generally known as cherry-tree gum. The irregular occurrence of gum on our wattles (for only some trees are gum-bearers, and only some branches even on those trees) led to the discovery that in the bark of gum-bearing branches certain bacteria, *B. acaciae* and *B. metarabinum*, live upon the sugar in the sap and convert it into gum; the former produce arabin, the latter metarabin. A tree at Mittagong in New South Wales furnished the original bacteria, and with them slimes were grown on plates of agar-jelly containing sugar. When heated under pressure the slimes were decomposed into (*a*) coagulated proteid and (*b*) a solution of gum which was adhesive, had all the chemical properties, and furnished all the decomposition products, of gum acacia. The second microbe (*B. metarabinum*), similarly cultivated, gave a tough slime like cherry-tree gum, which liquefied under steam pressure and again reverted to the insoluble condition when treated with alcohol. These two bacteria were shown to be the same when *B. acaciae* was inoculated into a peach-tree, and in course of time gum of the insoluble kind exuded. In the bark were found *B. acaciae*, *B. metarabinum*, and all stages between the two. Evidently the host-plant has the power of altering the physiological activity of the bacterium: and this is why certain species of wattle uniformly produce a certain kind of gum. Some trees always produce soluble, some insoluble gum, and some a mixture of the two. The character of the gum will also depend on the climate, for rain or dew will dissolve and wash away the soluble gum.

The gum of the kurrajong tree (*Sterculia diversifolia*) differs from wattle gum in certain characters; a bacterium from the bark, isolated and cultivated in the laboratory, produced a gum which proved to be pararabin—that obtained from the tree.

Living in conjunction with *B. acaciae* in the bark of such gum-bearing trees as the peach, almond and cedar, another bacterium was found, which elaborated a soluble gum that became insoluble on drying. This bacterium differs from those previously obtained in being a comparatively large spore-bearing rod.

Plants of the family Leguminosae have their roots studded with nodules containing myriads of dead and many living bacteria, *Rhizobium leguminosarum*. The gaseous fixation of atmospheric nitrogen, which is common to all leguminous plants, is associated with the growth of these nodules; and the writer has suggested that the bacteria utilize the saccharine matter of the plant to elaborate a nitrogenous slime, which in its turn causes the localized growth of the nodule. The production of slime appears to bear some relation to the fixation of atmospheric nitrogen, for laboratory cultures showed that the weight of

slime formed by the microbe was proportional to the weight of nitrogen gained from the air. Australia is the home of the acacia, and our soils should be rich in these nitrogen-gathering bacteria—as indeed investigation has shown. A good alluvial soil from the Hawkesbury Agricultural College contained over 11,000,000 bacteria per gram; and it was brought out during the investigation that the fertility of a soil is roughly proportioned to the number of rhizobia it contains.

The occurrence of ropiness or viscosity in industrial processes is fairly common. Country bakers are often troubled with ropy bread, the result of the activity of *B. vulgatus*. Milk, beer, wine, cider, vegetable infusions and ink all have their ropy or slimy diseases. Tanners sometimes find their liquors thus affected. In the winning of sugar viscosity is a serious fault, preventing crystallization; as the gum is formed at the expense of the sugar, the loss from both causes may be great. The gum-fermentation of cane-sugar juice is caused by *B. levaniformans*, allied to the potato bacillus (*B. vulgatus*). *B. levaniformans* feeds upon cane-sugar, changing it to gum levan, to invert sugar (a mixture of levulose and dextrose) and to certain acids. In cane-sugar juice the gum-fermentation is the pronounced phenomenon, for the viscosity is more apparent than the inversion of the sugar; but the bacillus is also to be found in the sugar-crystals, which it slowly alters, especially if they should become moist. It is also found in beet-sugar, in the soil and in the tissues of the plant—and the resulting loss is considerable in all parts of the world.

Milk is particularly prone to ropy fermentation. Some active slime-producers have large, swollen capsules, which by their mass constitute the trouble; other bacteria attack the lactose, and a few the casein. The 'jellification' of condensed milk has been investigated in Australia, and the active organism found to be an ally of *M. albus* which, while capable of producing the disease by itself, is ably assisted by salts of lime. In this case it is the casein, not the lactose or saccharose, that is 'jellified.' Another instance of the production of slime from proteid matter is found in the household bath-sponge, the proteid skeleton of which is, by the action of several micro-organisms, converted into a mass of useless slime. The most active of these organisms resembles in appearance the *Rhizobium* of leguminous nodules.

The ropiness of wattle-bark tan-liquors has been shown to be caused by at least two organisms, which alter the non-tannins (sugar) into a ropy slime. These bacteria are very sensitive to the action of certain salts; for example, a solution of three parts of sodium acetate in 10,000 parts of tan-liquor prevents their growth.

Waste bark from tanneries is utilized by the white lead manufacturer to corrode his lead. After a preliminary treatment, known as tempering, the moist tan bark is spread in a layer upon which is placed a number of earthenware pots containing dilute acetic acid below a number of sheets of perforated lead. A roofing of timber is laid over the pots. Then more bark is spread as a bed for more pots and thus a stack of some twenty tiers is built up. The bark begins to heat or ferment and during the fermentation, great quantities of carbon dioxide gas are given off. The combination of heat, acetic acid and carbon dioxide attacks the metallic lead converting it largely into basic carbonate of lead which, after being ground with water and incorporated with oil, becomes white lead pigment, the basis of many oil paints. During the fermentation of the bark, the temperature of the stack rises to 80°C. and the active agent is a bacterium which acts and thrives at this comparatively high temperature. It is a spore-bearing rod and the spores are very resistant to heat, being able to survive a dry temperature of 200° C. at which cotton wool is charred.

The action of disinfectants in improving the fertility of the soil is, according to Russell and Hutchinson, due to the fact that they destroy certain protozoa; when these are eliminated, there is a marked increase in the number of bacteria on which they would have fed, and which by breaking down the organic constituents of the soil render its nutritious elements more soluble. It had been previously noted, in experiments intended to eliminate soil-pests like phylloxera and nematodes, that the treatment not only destroyed the pests but actually augmented the yield of the crops.

Heat has much the same effect as disinfectants in increasing the fertility of soils, though possibly the method of action may be different; moreover, while a moderate heat is beneficial, a temperature of 135° to 150° C. brings about the production of certain soluble poisonous substances, which render the soil toxic to plants. It is difficult to judge the precise effect of bush-fires on the soil, but on the whole it is probably beneficial. The most apparent action of volatile disinfectants, or of a moderate heat, is to disturb the natural balance of the soil bacteria. The great bulk of the bacteria and (according to the moisture content) the bulk of the protozoa are destroyed, while the hardy spore-forming bacteria are left, and in time become exceedingly numerous—though the survival of some of the bacteria-destroying protozoa and other conditions tend to check increase beyond a certain level, and the number of bacteria in any particular soil may be considered stationary.

One reason for the maintenance of this bacterial level may be the retarding influence of the by-products or toxins of the bacteria themselves. These toxins are destroyed by a moderate heat and by sunlight, and, being soluble in water, are naturally washed out of the soil by rain. It is not always possible to obtain evidence of their toxic action. In the neighbourhood of Sydney they were found in winter, but never in summer, and generally after a short spell of cool, dry weather. They were capable of destroying a test bacterium; but, when a mixture of soil bacteria was introduced, they delayed or hindered the growth without destroying it. Heating the toxic extract to 94° or 100° C. caused the destruction of the toxin; the extract then became nutritive, and favoured a rapid growth of bacteria. Another reason may be found in the action of the volatile disinfectants as fat solvents. The fatty matter of the soil—the remnant of the ether-soluble matter of plant residues—is, presumably, impregnating the organic matter. It is dissolved by the disinfectant, and re-deposited, not upon the particles originally containing it, but upon all the particles of the soil. Thus the organic matter is less protected against bacterial attack, and also against the solvent action of the soil-water, so that it becomes fermentable and will support a more numerous population. To prove this hypothesis a column of soil was treated with chloroform and, after dispersal of the disinfectant, extracts were made from the layers of the column. The

extracts made from the lower layers always grew more bacteria than those from the upper layers, into which the fatty matter had been carried by the evaporating disinfectant. The matter is therefore complex, and controversies have arisen from attempts to explain the facts by one hypothesis.

Through the munificence of the late Sir William Macleay, the laboratory of the Linnean Society of New South Wales has become the Australian home of research in economic bacteriology. The details of the researches mentioned in this review will be found in the pages of the *Proceedings* of the Linnean Society of New South Wales. Certain State departments of agriculture also prepare and send out cultures of lactic bacteria for butter factories, and of nitrogen-fixing bacteria for agriculturists. R.G.S.

Badham, CHARLES (1813-1884), born at Ludlow in Shropshire on 18 July 1813, was a son of Charles Badham, M.D., F.R.S., regius professor of physic at Glasgow, and of Margaret Campbell, first cousin of the poet Thomas Campbell. Lewis Campbell, editor of Sophocles and Plato and professor of Greek at St. Andrews, was Charles Badham's cousin. The boy got his first schooling from Pestalozzi ('I was his favourite pupil' wrote Badham in 1876): thence he went to Eton and Oxford (B.A., 1836; M.A., Cant., 1846; D.D., Cant., 1852). His B.A. degree carried third-class honours only; Dr. Woolley, his predecessor at Sydney, gained first-class honours the same year. There followed seven fruitful years of Continental travel during which Badham ransacked libraries for Greek MSS, absorbed the languages and literatures of the major civilized nations, and—as the recognized heir of Porson, Elmsley, and Dobree, who taught Europe Greek from 1797 to 1825—made life-long friendships with the greatest classical scholars of the Continent. Cobet of Leyden was his dearest friend. Returning to England in 1846, he took orders with a view to scholastic work. The England of that time was capable of appointing Benjamin Jowett regius professor of Greek at Oxford and then withholding his stipend on account of his heretical views. Badham, though prized at home by many of the finest minds—Thackeray, F. D. Maurice, Lord Lyttelton, Thompson of Trinity—and fully recognized abroad (Leyden gave him its honorary D.Litt. in 1860 and its S.T.P. in 1864) could get nothing better than the headmastership of a proprietary school at Edgbaston near Birmingham—'in the land of the Chalybes,' as he puts it—but he had Newman as a neighbour. And then 'the one English scholar of the mid-century whose reputation crossed the Channel received from abroad the praises of his peers, but at home was excluded from academical preferment, set to teach boys at Birmingham, and finally transported to the antipodes,' says Professor A. E. Housman. That transportation was our great good fortune. As professor of classics and logic at Sydney from 1867 to the day of his death, he strove hard, in word and act, for a true and vital idea of education. His own private work was along the arduous and subtle lines of textual criticism, and in what used to be regarded as the 'higher mathematics' of that art—Plato's *Laws*: but as teacher, as orator, as man, he was the first and only 'democratizer' of the university. He it was who offered himself, free of cost, as private tutor to working-class students all over the colony; who stumped the country to found bursaries; who secured the establishment of evening lectures. It was fitting that his body should be borne to the grave by the bursars of that time, and that they should set over him the simple memorial which, as his widow says, was the only thing he would have desired. And when, from the official point of view, the professor of classics and logic was the only professor in the faculty of arts, he—being Charles Badham—was professor of ancient and modern, of universal and comparative literature. His published work comprises editions of the *Helena, Ion* and *Iphigeneia in Tauris* of Euripides; the *Euthydemus, Laches, Phaedrus, Philebus* and *Symposium* of Plato; an *Adhortatio* to Sydney undergraduates; and a posthumous volume of speeches and lectures delivered in Australia. But this very inadequately represents the learning and the genius of a man whom Grote describes as 'the greatest of living scholars,' Newman as 'the first Greek scholar of the day,' and the *Quarterly Review* as one who 'could impart instruction to the ripest scholars of the age.' He died on 26 February 1884 in the university building, which was his house and home. In January 1921 his widow enriched the university library with the gift of his classical books. C.B.

Baeckea, a genus of the family Myrtaceae, consisting of heath-like shrubs chiefly found in Australia, though a few species extend to New Caledonia, Malaysia, and south China. The flowers are white or pink, solitary or several together; calyx-lobes 5, often scarious; petals 5, usually rounded; capsule, enclosed in the calyx-tube, opening at the top in 2-3 valves; leaves small, opposite and entire. *B. virgata* is a tall graceful shrub, with flat leaves and flowers exceptionally large for the genus. *B. linifolia,* a tall, graceful shrub with fine cylindrical leaves and a profusion of white flowers clothing the slender, drooping branches, is usually found on the banks of watercourses.

Bagot, CHARLES HARVEY (1788-1880), born in Ireland in 1788 and trained for the army, served with distinction in the East Indies and had attained the rank of captain before he left the service. In 1840 he migrated to South Australia and took up land for a sheep-run at Kapunda. On this property copper was discovered in 1842, at first by Bagot's young son, then by Francis Dutton his overseer; Bagot and Dutton quietly bought 80 acres of the mineralized area, made a track to Port Adelaide (42 miles away) and opened up the famous Kapunda mine. In 1843 Bagot was nominated to the first legislative council, and sat in the council of 1851-6 (as member for Light) and in the first legislative council under responsible government; he was also in the council in 1865-9. As a politician his chief distinction was that he opposed Governor Robe both in his policy of state aid to religion and in his attempts to impose a royalty on minerals. He was above all things a pastoralist and stock-breeder, and made this the occupation of a long life, dying in Adelaide on 29 July 1880. His sons Christopher and Edward also occupied themselves with pastoral pursuits; but a grandson, JOHN BAGOT (1850-1910), son of Christopher, after spending many years in developing property in the Macdonnell ranges (where he was the first white man to greet John Forrest after his adventurous journey in 1874 across Western Australia), was persuaded by Josiah Symon to enter politics, and

in 1884 defeated a minister at the elections for the district of Victoria (the south-eastern region of the colony).

From a distinct Irish family came JOHN TUTHILL BAGOT (1818-1870), who in 1857-65 represented Light in the South Australian assembly, and was solicitor-general in the short-lived Baker ministry of 1857, commissioner of crown lands in the first Reynolds ministry (1860-1), and—having been elected to the legislative council in 1866—attorney-general in the second Hart ministry (1868) and chief secretary in the first Strangways ministry (1868-70). He died on 16 August 1870.

Bailey, FREDERICK MANSON (1827-1915), was the best-known of a family of botanists closely associated with practical work in Australia. His father, JOHN BAILEY (1800-1864), born at Hackney, London, was trained in the botanical nursery of Conrad Loddiges, then the most extensive in England, and in 1838 migrated to South Australia, taking with him a large number of vines, olives and other fruit-trees. On his arrival in March 1839 Gawler made him colonial botanist at a salary of £80 per annum, but Grey's retrenchments included this post, and Bailey established a private nursery, through which he introduced many valuable plants into the colony. He died in 1864.

F. M. Bailey was born at Hackney on 8 March 1827, and arrived in South Australia with his father in 1839. Taking up orchard-work, he migrated in 1853 to New Zealand, and to Queensland in 1861. In 1875 he was made botanist to a board appointed to deal with plant and animal diseases; later on he was in charge of the botanical section of the Queensland museum, and in 1881 was appointed colonial botanist. He was an indefatigable collector and author, and a fellow of the Linnean Society. Much of his work is summarized in three important publications—*The Queensland Flora* (6 vols., 1899-1902), *Weeds and Suspected Poison Plants of Queensland* (1906), and *The Comprehensive Catalogue of Queensland Plants, both Indigenous and Naturalized* (1912). Between 1874, when he privately issued his *Handbook to the Ferns of Queensland,* and 1915, when his latest *Contributions to the Flora of Queensland* appeared, he also wrote numerous botanical papers, and added a large number of species to the flora of Queensland. He died in Brisbane on 25 June 1915. (C.M.G., 1911.)

His son, JOHN FREDERICK BAILEY, born at Brisbane in 1866, was in 1889 appointed assistant to his father, in 1905 made director of the Brisbane botanic gardens, and in 1915 colonial botanist. In 1917 he resigned this post to become director of the Adelaide botanic garden. In Queensland he devoted much time to the investigation of the timbers of the State's tropical region.

Baker, JOHN (1813-1872), born at Ilminster in Somerset on 28 December 1813, migrated to Tasmania while still a young man. In 1838 he visited Adelaide, then newly settled; imported 10,000 sheep from Tasmania, under an arrangement with the South Australian Company; and, settling in 1839 permanently in South Australia, took up pastoral pursuits, bred and trained thoroughbred horses, and formed a company for the importation of draught horses. In 1850 he helped to found the Adelaide chamber of commerce (of which he was the first chairman), and in 1851 helped to establish the botanic garden, and was three times president of the Horticultural Society. He represented Mount Barker in the mixed legislative council from 1851 to 1856, and in 1857 was elected a member of the new council, holding the premiership of the colony for 11 days in August of that year. The seat in the council he held continuously until his death at Morialta in South Australia on 18 May 1872.

Baker, SIR RICHARD CHAFFEY (1842-1911), eldest son of John Baker (q.v.), was born at North Adelaide on 22 June 1842, educated at Eton and Cambridge (B.A., 1864; M.A., 1870), and called to the English bar at Lincoln's Inn in 1864. Returning next year to South Australia, he took up politics, and in 1868 entered the house of assembly as member for Barossa, becoming attorney-general in the Hart ministry from May 1870 to July 1871. Between 1871 and 1877 he practised his profession privately, but in the latter year was elected to the legislative council and held the seat till 1901, being president of the council from 1893 onwards. In June 1884 he took the ministry of justice and education in the Colton cabinet, retiring in June 1885 to represent the Australian colonies in London during negotiations for a renewal of the expiring mail contracts with Great Britain; in this connection he obtained important concessions. In March 1891 he was appointed one of the South Australian representatives to the federal convention, distinguishing himself as a champion of the smaller colonies. He was elected in 1897 as one of the ten representatives of his colony to the federal convention of 1897-8, which framed the present Commonwealth constitution, and became vice-president of that convention and chairman of committees. It was natural that, when South Australia chose its ten senators for the first federal parliament, Baker should be one of them; and when the senate met to choose a president he—having as aforesaid been president of the South Australian council—was the obvious choice. This post he held till the end of 1906, when he resigned his seat in the senate and retired into private life. He represented the Commonwealth at the Delhi Durbar of 1903. He died on 18 March 1911. He was the author of several pamphlets on constitutional subjects, and of a manual of authorities for the use of the 1891 convention. (C.M.G., 1886; K.C.M.G., 1895).

Balcombe, WILLIAM (1779-1829), entered the British navy early in life, but in 1807 is found at St. Helena in the employ of the East India Company as superintendent of public sales; he had also a share in a business for purveying stores to ships that touched at the island. When Napoleon arrived at St. Helena in October 1815, Longwood not being ready for him, he stayed for nearly two months in a pavilion attached to Balcombe's house, The Briars, and became very friendly with the family. When Napoleon removed to Longwood, Balcombe became purveyor to his household, and friendly visits were frequent; but Sir Hudson Lowe found occasion to believe that Balcombe was transmitting the prisoner's letters to Europe clandestinely and negotiating bills for him. Consequently in March 1818 the Balcombes left for England, and for the next five years lived in Devon. In 1823, however, Lowe and Balcombe were reconciled, and almost immediately afterwards Earl Bathurst appointed Balcombe colonial treasurer in New South Wales. It is likely that by 1823 Lowe had discovered his suspicions to be unjust; at any rate the appointment was avowedly a partial compen-

sation for the heavy losses Balcombe had incurred in the government service at St. Helena. His career as treasurer was in the main uneventful, though in 1826 he came into collision with Darling and Macleay over the affairs of the Bank of New South Wales, then badly managed and in serious difficulties. Balcombe was charged by Darling with having paid public moneys into the bank at a time when he should have known it was unsafe; but Bathurst, while agreeing that he had done wrong, merely ordered that in future the public funds should be equally divided between the two existing banks. Balcombe died on 19 March 1829.

His second son, THOMAS TYRWHITT BALCOMBE (1810-1861), became a locally notable artist; he made a portrait of E. H. Hargraves, and in 1852 illustrated the *Gold Pen and Pencil Sketches* of G. F. Pickering.

Ballot, VOTING BY. This system of voting was advocated in England as far back as 1780, and was the subject of many bills introduced in the British parliament from 1830 onwards (and invariably rejected by the house of lords); but the methods of balloting most commonly used nowadays are of Australian origin, and the first ballot law ever passed was that of Victoria on 19 March 1856. The honour of approving and introducing the system is keenly disputed between Victoria and South Australia.

Under the act of 1850 'for the better government of Her Majesty's Australian colonies' both South Australia and the Port Phillip district of New South Wales (the latter shortly to become the colony of Victoria) were given elected legislative councils, the machinery of which was to be provided by the already existing councils of South Australia (then purely nominee) and New South Wales (already partly elected). Agitation sprang up at once in Adelaide and Melbourne for the inclusion of the ballot in this machinery. The South Australian council, bombarded with petitions, disregarded them and in February 1851 passed an electoral act which insisted on open voting; the New South Wales council in April rejected a motion by William Westgarth (q.v.) designed to test its feeling on the question; and open voting continued for another four years. In 1855, however, the grant of new ('responsible government') constitutions to the eastern colonies afforded another opportunity of raising the issue as the methods of election, etc., were left to the decision of local legislatures. On 1 November 1855 Sir R. G. Macdonnell, then governor of South Australia, officially advocated the ballot in his speech opening the session of council, and on the 20th Francis Dutton and G. S. Kingston (father of C. C. Kingston) gave notice of motions favouring the ballot. B. T. Finniss, then premier, yielded to this pressure, no one drove opposition to the point of a division, and on 2 April 1856 the machinery bill containing provisions for vote by ballot (voters deleting the names of candidates they did not favour) became law. Meanwhile the Victorian council had been preparing its electoral bill, and on 18 December 1855 William Nicholson (q.v.) moved that the ballot be adopted. The fight was fierce, Haines (premier), Stawell (attorney-general), Fawkner, O'Shanassy and other prominent men denouncing the system in unmeasured terms; very little, indeed, was known about it, for Stawell thought it would be worked with peas or marbles, and Nicholson himself had an idea of providing coloured boxes to receive votes for different candidates. The motion was carried against the government; Haines resigned; Nicholson after many attempts failed to form a ministry, and Haines, compelled to resume office, declared that he personally would oppose the ballot but the ministry would leave it an open question. H. S. Chapman (q.v.) now came to the front, and drafted a series of machinery clauses for Nicholson's adoption; these were included in the government's bill, and became law on 19 March 1856. Thus the Victorian act was slightly the earlier, though the South Australian proposals had been made first, and Westgarth in New South Wales had been the pioneer of the whole movement. Both colonies adopted the same mechanism, South Australia having a slight priority in this respect also; but in 1858 a new South Australian act introduced the method, invented by W. R. Boothby (q.v.), of printing a square opposite each candidate's name on the voting paper, and requiring the voter to put a cross within the square opposite the name of the candidate he favoured. Tasmania and New South Wales came into line in 1858; Queensland inherited the ballot when it was separated in 1859; Western Australia adopted it in 1870, and New Zealand in the same year.

The Australian ballot was adopted in Britain in 1872, in British Columbia in 1873, in the Dominion of Canada in 1874, in Belgium in 1877, and in Massachusetts, U.S.A., in 1888, other States of that Union following suit during the next 15 years. The British and Canadian methods are essentially South Australian; the Belgian ballot-paper provides for party 'tickets;' but the ballot-papers issued in the United States are monstrous sheets on which a voter has to mark his choice of sometimes hundreds of candidates for dozens of offices, as well as his attitude towards 20 or 30 pieces of legislation. The cross is the usual mark.

Baloghia, a genus of the family Euphorbiaceae, consisting of a few species, chiefly found in New Caledonia. *B. lucida*, the only species indigenous to Australia, ranges from New South Wales into Queensland. On the northern rivers of New South Wales it is known as 'scrub' or 'brush' bloodwood, and by the aborigines as 'dooragan.' The sap is blood-red, and makes an indelible paint, which has been used for marking bags, blankets, etc. A vertical incision is made in the bark, and a 12 hours' flow produces about half a pint. The wood (light brown in colour) is fine and close-grained; it shows no tendency to split, and is impregnated with a resinous substance which burns readily in a green state.

Bananas of the plantain variety have been grown as garden plants round Sydney since the earliest days of settlement. Their cultivation for the market was undertaken first in the Gosford district, and has since been established as an important industry in the valleys of the Richmond and Tweed, where in 1922-3 3807 acres were under cultivation, producing fruit valued at £210,170. In Queensland the banana is at home near the coast, particularly in the north, where its cultivation was for many years (and still partly is) carried on by Chinese; but European labour and methods and the use of manure have produced better crops. In northern Queensland the industry is diminishing, partly through the substitution of sugar-cane; in the south-eastern districts, under more favourable conditions of transport, it is develop-

ing fast, a protective duty having been imposed on imported bananas. Bananas are also grown in Western Australia, but on a very small scale. The total Australian crop for 1922-3 was valued at £660,825, grown on 14,619 acres. The types cultivated include not only many varieties of the ordinary banana (*Musa paradisaica*, var. *sapientum*) but also the so-called Chinese or Cavendish banana (*M. Cavendishi*), a cool-climate type with a comparatively thin rind and a delicate flavour.

In 1922-3 the disease known as 'bunchy-top,' whose origin and nature is still uncertain, did much damage in the plantations of southern Queensland and New South Wales. In August 1924 an otherwise unidentified organism was discovered in the roots, corms and leaves of affected plants, and this is being experimented with as a likely cause of the disease; its non-discovery earlier is probably due to the fact that it is motile only at certain seasons and quiescent during the greater part of the year. The university of Queensland is experimenting with plants resistant to the disease.

Bancroft, JOSEPH (1836-1894), born at Stretford near Manchester in the first half of 1836, and trained for the medical profession (M.R.C.S. Lond., M.D. St. Andrews), at first practised at Nottingham, where he developed a liking for the investigational side of his profession; he also became interested in the problem of packing salmon and trout eggs for transmission to Tasmania and New Zealand, and himself helped to pack the first batch of trout eggs that reached Tasmania alive. In 1864 he migrated to Australia and settled down to practise in Brisbane, but gave up a great part of his time to the study of hybridization, the pharmacology of the local flora, and the diseases of the banana and sugar-cane. He produced new varieties of strawberry, grape and castor oil plant, some of which proved commercially useful; he also made many experiments with the object of producing a wheat that could be cultivated profitably in a subtropical climate, established works for the preparation of a form of pemmican that found favour with the British war office, and devised a useful method of preserving fish. His investigations into the properties of the pituri plant led to the discovery of the mydriatic properties of a near relative, *Duboisia myoporoides*, which have placed its alkaloid, duboisin, in the Pharmacopoeia; another of his researches brought about the inclusion in that list of the bark of *Alstonia constricta*.

His most important discovery, however, was that (made in 1876) of the adult female form of a *Filaria*—named after him, by Cobbold, *Bancrofti*—which is responsible for many diseases of the lymphatic system in man. Early in 1877 he suggested that the embryos of these filariae were sucked in by mosquitos when biting human beings, and the same year Patrick (afterwards Sir Patrick) Manson in China, working independently, confirmed the suggestion by actual discovery; it was believed, however, that the young filariae, after metamorphosis within the mosquito, transferred themselves to water and were later introduced to human bodies in the act of drinking. In 1899 THOMAS L. BANCROFT, a son of Joseph Bancroft, suggested 'that the young filariae may gain entrance to the human host while mosquitos bearing them are in the act of biting,' and this was confirmed definitely both by himself and by Dr. G. C. Low. It was the discoveries and suggestions of Manson and the elder Bancroft that guided Ronald Ross to his parallel discoveries (1895-8) concerning the life-history of the malaria parasite in mosquitos; and the Bancrofts, father and son, may thus be considered pioneers in the development on which practically the whole of recent tropical medicine is founded. Joseph Bancroft, who was at one time president of the Royal Society of Queensland, died at Brisbane on 16 June 1894. —T. L. Bancroft has of late years turned his attention to breeding varieties of cotton-plant suited to the climatic conditions of Queensland (for details see COTTON), and samples submitted to the experts of the Imperial Institute in 1924 were favourably reported on.

Banded Anteater (*Myrmecobius fasciatus*), one of the most remarkable Australian marsupials, is usually classed with native cats in the family Dasyuridae, but by some zoologists is placed in a family by itself. Its size is that of a rat or squirrel; it has a light, graceful body, broad head and elongated sharp muzzle, pointed ears, long flexible bushy tail, and rather slender limbs, the hind pair longer than the fore. The rather coarse fur is reddish on the upper surface, darkening behind and crossed by nine bands of white; a white band occurs over the eye; the lower surface is pale yellow. The fore-limb has five clawed digits, the hind-limb only four, the first toe being absent. The teeth are remarkable on account of their number, which is greater than in any other marsupial or mammal, except the American armadillo and certain Cetacea. The female has no pouch.

The marsupial anteater is found only in certain districts of South and Western Australia. It is not nocturnal, but seeks its food—mainly ants, white ants, and sometimes other insects—by daylight. The ants are captured by means of the long narrow tongue. See MARSUPIALS.

W.A.H.

Banded Sea Perch, a rock-haunting species (*Gilbertia annulata*) which is not uncommon on the coast of New South Wales, though it rarely appears in the markets. It is marked with conspicuous black bands on a reddish ground, and its fins are deep scarlet. Smaller allied species, such as the Half-banded Sea Perch (*Gilbertia semicincta*) are commonly taken by seine-net fishermen in inlets along the coasts of the southern half of Australia.

A.R.McC.

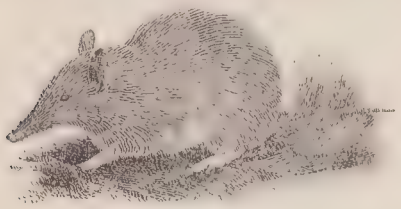
Banded Wallaby, a small wallaby (*Lagostrophus fasciatus*) living in scrub and on the margins of swamps in Western Australia. It differs from wallabies of the genus *Macropus* (see KANGAROOS AND WALLABIES) in various features of the skull and teeth, in having the two halves of the lower jaw immovably fused together, and in having the feet covered with long coarse hairs, which completely conceal the claws. The fur is thick and soft, of a general grey-brown colour above, with cross bands of white and black on the back; the lower surface is a mixed grey and white. The tail is uniformly covered with short close-set hairs, which are yellowish-grey above and dull yellow below; there is an inconspicuous pencil of longer hairs at the tip. See MARSUPIALS. W.A.H.

Bandicoots, a family (Peramelidae) of polyprotodont marsupials of small or medium size, insectivorous or omnivorous and of burrowing habits, restricted to the Australian re-

gion. The Common Bandicoot (*Isoödon obesulus*) occurs throughout extra-tropical Australia, including Tasmania; the Long-nosed Bandicoot (*Perameles nasuta*) is restricted to the eastern

Common Bandicoot.

districts, the Long-tailed Bandicoot (*I. macroura*) to northern Australia, and Gunn's Bandicoot (*P. gunni*) to Tasmania and south-eastern Victoria; the Striped Bandicoot (*P. bougainvillei*) ranges from Western Australia to New South Wales. Other species are found in Papua (five species), the Aru Islands, New Britain, and Duke of York Islands. All bandicoots are rat-like or rabbit-like animals with (in most species) coarse, bristly, brown fur, and long muzzle. The hind-limbs are rather longer than the fore-limbs. The fore-limb has the three middle digits long and clawed, the two outer being rudimentary or absent. The hind-limb has the first toe short and clawless; the second and third slender, with flat twisted nails, and united together throughout; the fourth long and powerful, with a strong pointed claw; the fifth like the fourth, but smaller. The length of the snout, ears and tail varies considerably in different species; the tail, usually long and hairy, is not prehensile. The teeth are numerous (46 or 48). The pouch of the female opens backwards. There are six or eight teats. Alone among marsupials the female bandicoot has a placenta; further discussion of this remarkable phenomenon will be found under MARSUPIALS.



Long-nosed Bandicoot.

Bandicoots live usually in companies or associations, and excavate burrows, numbers of which, branching in all directions, may form a veritable warren. In the open they run quickly, with movements not very different from those of a rabbit. Their chief food is of a vegetable character—mainly roots, bulbs, and tubers—and their burrows are excavated in search of these as well as for the sake of shelter. They also eat earthworms and a variety of insects, and are fond of grain of any kind. Useless to man as far as their fur and flesh are concerned, bandicoots, where they occur in large numbers, are capable of doing extensive damage—by their burrowings as well as by the loss of what they actually consume—to crops of potatoes, roots and grain. They may also cause much loss if they gain an entrance to granaries or wheat-stacks; but their inability to gnaw makes it easier to guard against them than against rats or mice.

Besides the ordinary bandicoots (*Isoödon* and *Perameles*), two other genera, *Choeropus* and *Thalacomys*—both confined to the inland parts of Australia—are comprised in the family Peramelidae. The Pig-footed Bandicoot (*Choeropus castanotis*) is so named on account of the structure of the fore-foot; this has a superficial resemblance to that of the pig, owing to the suppression of the first and fifth digits and the reduction of the fourth, the second and third alone being fully developed. It is a slight animal, smaller than a rabbit, with coarse straight fur of a general grey hue with a touch of fawn. The ears are long and narrow, chestnut on the backs, darkening towards the tips. Both pairs of limbs are long and thin. The hind-foot virtually consists of the large third toe. The tail is about half the length of the body, cylindrical, with a short inconspicuous crest above.

The Rabbit-bandicoot or Rabbit-rat (*Thalacomys lagotis*) is an animal about the size of an

Rabbit Bandicoot.

ordinary rabbit, but of slighter make. The snout is long and narrow, the ears very long. The hind-limbs are slender, and longer than the fore-limbs. The structure of both pairs is essentially the same as in *Perameles*, except that in the hind-foot the first toe is absent. The fur is long, soft and silky, of a general fawn-grey above, white below. The tail is about as long as the trunk, hairy throughout, the middle third black, the terminal third white. The flesh of the rabbit-bandicoot is said to be edible, and is highly valued by the natives.

The name 'bandicoot' is a corruption of a Telugu word meaning 'pig-rat,' and was originally applied to a large species of rat common in southern India and Ceylon. There is no evidence to show how it first came to be applied to the Australian animal, but Collins in 1802 (apparently reproducing Bass in 1799) uses it without explanation as a well-known name. See MARSUPIALS. W.A.H.

Banfield, EDMUND JAMES (1852-1923), born at Liverpool in England on 4 September 1852, was brought while a boy to Victoria by his father, who settled in Ararat. Adopting journalism as a profession, he worked on many newspapers in the three eastern States, during the nineties reaching Townsville in Queensland, where he joined the staff of the *Cleveland Bay Times*. Here after a few years of strenuous toil he was warned that phthisis would probably kill him within six months; he therefore abandoned journalism, and took a lease of Dunk Island—an islet about three miles square, lying off the Queensland coast half-way between Townsville and Cairns. From 1897 to 1923 he and his wife lived on this island simply and

healthily, Banfield devoting himself to the close study of tropical nature and of the aborigines of northern Queensland; he embodied his studies in *Confessions of a Beachcomber* (1908), following it up in 1911 with *My Tropic Isle* and in 1918 with *Tropic Days*—books that can never lose their charm or their value. He died on Dunk Island on 2 June 1923. *Last Leaves from Dunk Island* was posthumously published in 1925.

Banking. Sir John R. Paget, the greatest living authority on banking law, said in 1916 that no one was really a banker who did not habitually pay out money on cheques, and that nothing was banking business which did not include habitual payment of cheques. In 1915 Sir Samuel Griffith, late chief justice of the high court, declared that in Australia the term had never been used except to designate incorporated banking companies carrying on the ordinary business of banking, although it had sometimes been used by moneylenders in order to deceive the public. In his opinion, an institution upon which it was not lawful to draw a cheque was not a bank within the meaning of the bills of exchange act. In this article Griffith's definition has been accepted, and only cheque-paying banks are dealt with.

A description of banking as practised in Australia to-day would have horrified an English banker of a century ago, but happily the heresy of one generation often becomes the orthodoxy of the next. It cannot be claimed that any one of the leading traits which characterize contemporary banking practice in Australia is by itself peculiar to the country. It is rather in their combination and rapid adaptation that the distinguishing feature is to be found.

The branch-bank system has held the field from the beginning. The only known record of the existence of a private bank is in Widowson's *Present State of Van Diemen's Land* (1829), where it is stated that the Gellibrands, father and son (see GELLIBRAND, JOSEPH TICE), had a private bank in Davey-street, but did very little business. Until 1924 (see COMMONWEALTH BANK) there was never a banking monopoly in notes held by a privileged central institution, such as exists in England—where out of less than £30,000,000 worth of circulating notes over £29,000,000 worth are issued by the Bank of England. In Australia all banks had equal rights; when in 1910 the Commonwealth taxed bank-notes out of existence (substituting for them treasury notes under direct government control), they had long since become a minor factor in banking operations. Modern Australian banking business is based on deposits, and—except by a few recently established banks—interest is allowed only on deposits fixed for a term. Such fixed deposits permit of a greater range in making advances, and consequently (or concomitantly) the banks lend money freely on land. But land in Australia is usually a readily realizable security—at a price.

Thanks to Sir R. R. Torrens (q.v.) and the registration system, land can be transferred or mortgaged easily, cheaply and quickly, the validity of its title remaining beyond doubt. Banks also make advances on the security of growing crops, wool (even while on the sheep's back) sheep, and cattle, laws having been made to permit of acquiring valid security over these chattels. Banks also buy gold, and in the days of the early rushes this was a most important and profitable part of their business. Each of these departures from the orthodox tradition has been made under the stress of circumstance; but the Australian banker has never questioned the application to himself of the maxim that his success or failure is to be measured by the liquidity of his advances. In other words, his first duty is to his depositors, and to keep faith with them his investments must be of a readily realizable nature. The great crisis of 1893 may be regarded as the culmination of a period when this principle seemed to have been forgotten. That, however, was a national aberration, when even the wise and experienced were swept along in a current of unreasonable optimism. No country has escaped experiences of this sort, and no banking system ever invented by the brain of man can do more than alleviate the results of human folly.

Enterprising as the banks have been, they have never been lured into directly investing their funds in commercial or manufacturing enterprises, although much has been heard of German practice in this respect. In this they have steadfastly adhered to British tradition. There have been instances of banks affiliated to land companies, but the experiments were unhappy and not persisted in.

Australia, however, was and is primarily a pastoral and agricultural country; had the banks limited their business to discounting commercial bills, they would to-day be struggling for a precarious existence, instead of occupying a dominant position in the financial life of the country. They might, indeed, have been shouldered out by more vigorous rivals, capable of adapting themselves to the new environment. An illustration from the history of the United States will point the moral. According to the theory of banking which prevailed in America as late as the end of the 19th century, the chief function of a bank was to issue notes and discount bills. Hence the act establishing 'national' banks, although it authorized them to receive deposits, practically confined them to commercial deposits, because they were empowered to lend money only upon, or in discount of, commercial paper or bills of exchange. These national banks were created to help the government in financing the civil war, and no doubt served that purpose well; but, with the rapid reconstruction which followed the establishment of peace, the legal restriction on their powers prevented them from expanding as they might have done, and to maintain their place they had to ally themselves with trust companies or go under. These trust companies are practically banks, and absorb an increasing proportion of the real banking business of the country.

Australian banks, on the other hand, have been little hampered by legal regulations, and have been practically free to develop their usefulness, controlled only by public opinion. Publicity has been the rule from an early date, the banks having for many years been compelled by law to furnish to the government quarterly sworn statements of the average weekly balances, as explained below. One other characteristic may be mentioned. The banks make advances on current accounts by way of overdraft, and the tendency of this form of accommodation to displace bills of exchange, especially between wholesale houses and retailers, dates back many years and has been of steady growth. The shopkeeper who can, with the help of his banker, pay cash is free to buy where he likes, and in the long run all parties appear to benefit. Such are the chief characteristics of banks in Australia.

Legislation.—Banking is within the scope of the powers delegated to the Commonwealth parliament, but these have not yet been exercised with respect to the regulation of banking operations in general. State laws concerning banks (other than those enforcing publicity) are of small importance, and space does not permit of reference to them. As indicated above, Australian banks have developed with the country, and have adapted themselves to the growing needs of its commerce and industry. Freedom has been the rule; where restrictions (either legal or institutional) have proved irksome, they have been avoided or circumvented—sometimes even defied. Most banks that carry on business in Australia are incorporated under the companies' act. The others are under special acts of parliament, royal charter, or acts in council. The oldest, the Bank of New South Wales, was established in 1817 by an act in council, and re-incorporated by a New South Wales act of parliament in 1850.

Probably no act of parliament touches the banker's daily life at so many points as the bills of exchange act. Each colony had an act bearing this name, and closely modelled on the British act; but in 1909 these were replaced by a federal act which is practically identical with the British act. This facilitates business intercourse with the motherland, and makes available for general guidance the wealth of experience embodied in British textbooks and in the decisions of English judges.

Two other groups of laws have had a far-reaching influence on the development of Australian banking, and deserve more than a brief reference. The real property acts, by providing for registration, mortgage, and transfer of freehold lands at a very low cost, place a sound security in the hands of farmers and pastoralists who desire to borrow money to carry on their businesses. It must be reiterated that Australia is essentially an agricultural and pastoral country. Even to-day the greater portion of occupied Australia is held by pastoralists under lease from the crown. Before the discovery of gold, the wealth of the enterprising part of the community was in sheep and cattle, grazing on land to which the user had no title, or a very precarious one. Profits for a time were large, and this as usual led to riotous speculation, followed by the inevitable collapse (1823-1830). Having no security to offer, men of considerable wealth were reduced to bankruptcy. To meet the need of the moment, the New South Wales council passed an act 'to give a preferable lien on wool from season to season, and to make mortgages of sheep, cattle and horses valid without delivery to the mortgagee.' This was too revolutionary for the conservative mind of the colonial authorities in London, and was so repugnant to English commercial law that the act was vetoed several times; but the pertinacity of the men on the spot, who knew what they wanted, at last prevailed, and consent was given. Credit was re-established. The squatter, with a good security to offer, could turn part of the only wealth he had into money by pledging the whole, and could thus carry on his business. However it might perturb foreign legists, it soon became possible in Australia to hear that a grazier had borrowed money from one man on the security of his sheep, and from another on the pledge of his wool, while yet on the sheeps' backs. The climax was complete when the borrower, if possessed of freehold, obtained money from a third person by mortgaging his land. Crown leases soon became valuable, and provision was made to enable mortgages to be given over them, while a registered lien on a growing crop was legalized for the benefit of the agriculturist, whether freeholder or tenant. Australia is probably the pioneer in inventing an effective method of security over chattels that remain in the actual possession of the borrower.

Branch-bank System.—Australian banking institutions naturally bear the stamp of their British origin. Their salient features, however, derive more from Scotland than from England—notably the branch-bank system, and the advancing of money on current account. Also, until the Commonwealth monopolized the note issue, Australian banks, like their Scottish brothers, enjoyed the unfettered privilege of circulating their own paper in notes as low as £1. Scottish banks were firmly established in the 18th century as corporate bodies with numerous branches, so the safety and utility of this system had been tested by experience before Australia was founded. Historians of the industrial and commercial progress of Scotland always stress the potent influence of its banking system, and it is difficult to conceive what Australia's financial story would have been without its branch banks. Some other instrument might have equally well promoted its astonishing progress, but it is difficult to imagine what other kind of institution could have carried such abundant supplies of capital, at so small a cost, to the remote settlers in a sparsely populated land. The fierce opposition in the United States to the branch-bank system is incomprehensible to Australians. Complaints are occasionally heard here that too much money is withdrawn from the country districts to be used in the cities. Even if this had to be admitted, the advantages have on the whole been overwhelming. Probably in no other country do so many people (proportionally speaking) use a cheque book, and in no other country can remote settlers arrange loans so easily—for large amounts if necessary—at a branch office of a powerful bank. Keen competition has carried banking facilities into the most sparsely populated districts; the depositor has the security of an institution with large resources, which in turn are at the disposal of the borrower; the manager is under the control of men of wide experience, who command the means of meeting his requirements if he can justify them. The rapid development of Australia, especially since the gold discoveries, would have been impossible without a vast influx of British capital. The banks were the conduit-pipes through which it flowed, and its direction was largely determined by those responsible for their management.

The technical efficiency of banking in Australia is also of a high order, and will stand comparison with any known elsewhere. The Imperial Bank of Germany, in an annual report published during the war, thought it worth while to boast of having devised a scheme by which a payment could be made by a person in one town to a person in another by a book entry and letter of advice, without the use of currency or a credit instrument. If there is a banker living in Australia who can remember the time when a proposition of this kind was a problem to be solved, he must be a very old man.

Publicity.—In addition to publishing half-yearly or yearly balance sheets, every bank in Australia is compelled by federal law to supply the Commonwealth statistician quarterly with a sworn statement of its total averages, and by

State laws to furnish to the State government quarterly a similar statement of its assets and liabilities; these are published, in the press, and freely commented on by those interested in finance. The particulars supplied include deposits by the crown and by the public, notes and bills in circulation, balances due to other banks, and, on the assets side, cash, property, and all debts due to the bank. The ratio of liquid resources to the bank's liabilities—the sheet-anchor of sound banking—is thus revealed, and deviations from sound practice incur caustic criticism. The figures being weekly averages, the process known in England as window-dressing is reduced to a minimum. The public is protected, and one salutary restraint at any rate is placed on a banker disposed to rashness. A reform in this direction is much discussed at the present time in England, but a proposal to follow Australian practice would be regarded as extremely drastic, although two generations at least of Australians have been familiar with it.

Banking Business.—The great majority of Australian banks do not allow interest on current accounts. Five shillings per half-year is charged for keeping the account, and customers refund the price of the duty stamps which are impressed on cheque-forms for convenience at a government office. Fixed deposits are taken for 6, 12, and 24 months; for these interest is allowed, and receipts are issued, which are not transferable. A commission is charged for collecting cheques drawn on places outside the town where the deposit is made; as in Scotland, the charge is made at the time of each transaction. The rate varies roughly with the distance, but is usually uniform for all places within a State; in Queensland and Western Australia, however, the enormous distances between branches make very considerable variations necessary. One or two recently established banks both allow interest on current accounts and refuse to charge the half-yearly fee for keeping an account.

Though a bank's first business is to discount bills of exchange, a large part of the Australian banks' funds are loaned out on current account —that is, the bank allows a customer to overdraw up to a certain limit upon a more or less definite undertaking as to repayment. The rate of interest charged is about two per cent above the rates allowed on fixed deposits, and is calculated on the average daily balance of the actual advances; the customer has the right to pay off the overdraft without notice at any time.

The second function of a modern bank, the transfer of money from place to place, is in Australia performed with great thoroughness. Within the country the means employed are drafts, warrants, simple letters of advice, or telegrams; or travellers may carry a letter of credit which enables them to get cheques cashed in any place where there is a bank.

Foreign Exchange and Credits.—Nearly the whole of Australia's foreign trade, both imports and exports, is settled in London in sterling. The monetary unit of both countries being the same, exchange problems are simple compared with those of foreign bankers; but, as trade with America and the East grows, this simplicity may disappear. Australia being a gold-producing country, the banks were before the war frequent shippers of gold; occasionally they made shipments to India and the United States, but only to get the equivalent in London at less cost than by direct shipment. When the unlimited export of gold was prohibited, the gold-producers were permitted to form a company, to which was granted a licence to sell a limited amount of gold abroad for whatever currency could be converted at best advantage into Australian legal-tender money. For instance, in June 1921 it was reported in the public press that the association had sold 164,794 oz. in New York for 3,500,000 dollars; this made the net price in Australian currency approximately £5 8s. per oz. fine gold, or £3 17s. 10½d. for standard gold.

The Australian banks have correspondents in the principal cities of the world, and collect or pay debts due therein by bills of exchange. Travellers are supplied with circular letters of credit, which enable them to obtain foreign money in exchange for drafts on London. Documentary credits, varying in form, are supplied when required to cover imports into Australia. Before each wool season foreign banks establish credits with Australian banks, through which the buyers who arrive from abroad obtain the means to make their purchases; it is usual to lodge the shipping documents with the Australian banks as security. Other sales are financed in a similar way, and the keen competition for this class of business secures its working with a minimum of friction.

Clearing-house System.—Melbourne adopted the clearing-house system in 1868. Until 1914 all settlements were made in sovereigns. A pool for a substantial amount was formed, and the money placed in the control of three bank-directors, who issued certificates of £500 and £1000 denominations to the banks for their contributions to the pool. In Sydney the system (which was not adopted until 1894, owing to the opposition of some of the banks) differs somewhat in operation from that of Melbourne.

Bank-notes.—To meet the urgent demand for a regular currency (q.v.) the Bank of New South Wales was established in 1817. Notes were also issued by private traders until 1826, when this practice was officially suppressed, and by the various banks established before the gold rush. The discovery of gold, followed by the establishment of branches of the royal mint in Sydney and Melbourne, solved the currency problem of the colonies, and the rapid growth of the cheque-system soon made notes a negligible factor in banking operations. Australia affords no instance of reckless banking based on notes. In 1910 the Commonwealth government began to issue its own notes, and brought the banks' privilege to an end by a tax of 10 per cent per annum on their circulation. For years the banks had been paying a tax of two per cent to the various State governments (three per cent in Queensland), and it is doubtful whether they suffered any direct pecuniary loss by this action; it deprived them however, of facilities for supplying their numerous branches with till-money, and of coping by means of an increased note issue with the seasonal fluctuations in the demand for currency due to the marketing of wheat, wool, etc. A Commonwealth act (No. 11 of 1910) authorized the federal treasurer to issue notes, holding against them a gold reserve of not less than one-fourth of the total issue up to seven millions, and pound for pound for any sum in excess of that amount. An amending act in 1911 required that he should hold one-fourth of the total amount. The rest of the money derived from the issue he might invest on deposit in any bank, or in securities of the United Kingdom, the Commonwealth, or any

State; in 1920 his sphere of investment was extended to include trade bills with a currency of not more than 120 days. He was forbidden to pledge notes with any bank or person for money, but he might sell treasury bills for the redemption of his notes, if required. The 1910 act provided for full convertibility of the notes, and left the determination of the amount to be circulated at any time to the demands of the public. This amount on 3 August 1914 was £9,854,923; on 30 June 1923 it had risen to £52,102,025, a reserve of gold coin and bullion to the sum of £24,346,328 being held against this amount. By an act passed in 1920 the management of the note issue was transferred to the Commonwealth Bank, acting through a special board consisting of the governor and secretary of the bank, a leading treasury official, and two outside financial experts. For recent modifications of this scheme see COMMONWEALTH BANK. Statistics relating to the issue are incorporated (under a separate heading) in the balance-sheet of the Commonwealth Bank, though the notes remain treasury notes.

Financial Crises.—Australia has experienced its full share of violent financial crises. Over-speculation in sheep and cattle between 1825 and 1830 ended disastrously; again in 1842-3, after a land boom, the New South Wales banks, owing to the withdrawal by the government of its deposits in order to meet special obligations, were forced to restrict credit to such an extent that the whole financial machinery of the country was upset. Gipps, however, attributed the crisis entirely to over-speculation and the facility with which persons of no real substance obtained discounts at the banks. Capital had poured into the country rapidly between 1834 and 1840. In 1834 there were two banks in the colony with total paid up capital of £84,321; on 1 January 1843 there were seven banks with total paid up capital of £2,300,955; yet at the same time interest on money continued to rise reaching, in some cases, 15 per cent in Sydney. The banks as a rule weathered these early storms, and comparatively few failures were recorded. The Bank of Australia (Sydney, 1826) and the Royal Bank of Australia (London, 1840)—not to be confused with the present Royal Bank of Australia Limited—were liquidated in 1848. The Bank of Queensland failed in 1866, and the Oriental Bank Corporation in 1884, and a few other banks were absorbed. These, however, were mere financial ripples compared with the cataclysm that overwhelmed the banking world in 1893. Victoria was the storm-centre. For a decade English capitalists had been investing freely in Australia; according to the estimates of H. G. Turner, in 1885-91 £38,000,000 of borrowed money entered Victoria—an almost incredible sum compared with the population. This money, shared by land companies, mortgage and investment companies, building societies, municipalities, etc., was for the most part squandered in unnecessary undertakings. The market was flooded with land bills. Desperate efforts postponed the crisis until 1893, and then there was a panic. The Victorian government, by proclaiming a moratorium for five days (1-6 May 1893), increased the confusion. However, four banks—the Bank of Australasia, the Union Bank of Australia, the Royal Bank of Australia, and the Bank of New South Wales—refused to close their doors, and the others gradually resumed work. During the crisis 12 institutions, having 965 branches throughout Australia, with aggregate liabilities of over £100,000,000, had suspended business. Eleven of these banks were reconstructed, a portion of their liabilities being converted into fixed capital in the form of preference shares or stock. Only ten banks weathered the crisis; 23 failed between July 1891 and May 1893—five in 1891, four in 1892, and 14 in 1893. In New South Wales the pressure was relieved by the action of the government in making bank-notes legal tender and a first charge on assets for six months; nevertheless the colony suffered severely. The other colonies were more or less drawn into the vortex; the Queensland government took over the note issue in that colony, and maintained the monopoly until, nine years later, the Commonwealth authorities took control of the currency. The period of recovery was long and painful, the depression being prolonged by the low world prices obtaining at the time.

Banks.—Besides the Commonwealth Bank (q.v.) there are now 18 banks doing business in Australia, of which three have their head offices in London, five in Sydney, four in Melbourne, and one each in Brisbane, Adelaide, Perth, and Wellington (N.Z.). The Comptoir National d'Escompte de Paris and the Yokohama Specie Bank of Japan have branches in Sydney and Melbourne. The Ballarat Banking Company is a small bank with a local business. The bank amalgamation movement, so pronounced in Britain in recent years, has had its lesser counterpart in Australia, five amalgamations of two banks and one of three having been effected since 1917.

Statistics.—As several banks that do business in Australia have branches in New Zealand, and the Bank of New Zealand, whose head office is in Wellington, has branches in Australia, it is impossible to ascertain accurately the amount of banking capital employed in the Commonwealth. But the paid-up capital of the 19 banks that do business there was on 30 June 1923 over 52 millions, though of this 20 millions is accounted for by the two foreign banks with headquarters in Paris and Yokohama: the reserve profits of the 19 banks amounted to over 37 millions (over ten millions belonging to the two foreign banks). Roughly speaking, the assets of banks operating in Australia are cash and reserves, 47.1 per cent; advances, 51.4 per cent; premises, 1.5 per cent. Their liabilities are to shareholders, 12.1 per cent; to the public, 87.9 per cent. Very full details of assets and liabilities may be found in the successive Commonwealth Year Books and in the *Insurance and Banking Record.*

By the Commonwealth bank act the following institutions are recognized as banks in Australia:—

Australian Bank of Commerce.
Ballarat Banking Co. Ltd.
Bank of Adelaide.
Bank of Australasia.
Bank of New South Wales.
Bank of New Zealand.
Commercial Bank of Australia, Ltd.
Commercial Banking Company of Sydney, Ltd.
Commonwealth Bank of Australia.
Comptoir National d'Escompte de Paris.
English, Scottish and Australian Bank, Ltd.
Federal Deposit Bank, Brisbane.
Rural Bank of New South Wales.
National Bank of Australasia. Ltd.
Primary Producers' Bank of Australia, Ltd.
Queensland Deposit Bank and Building Society, Ltd.
Queensland National Bank, Ltd.
Royal Bank of Australia, Ltd.
Union Bank of Australia, Ltd.
Western Australian Bank.
Yokohoma Specie Bank, Ltd.

J. T.

Banks, Sir Joseph (1743-1820), only son of William Banks of Revesby in Lincolnshire, was born in Argyle-street, London, on 13 February 1743, and educated at Harrow, Eton and Oxford. During his first year at the university (1761) his father died, leaving him Revesby with an ample fortune; and in December 1763 he left Oxford with an honorary degree (M.A.), determined to devote himself to the study of natural science. Even at Eton he had begun this, picking up botanical facts from 'wise women' in the villages round Windsor and from torn old books discovered at home; and at Oxford, finding that botany was not taught there, he imported a lecturer from Cambridge—Israel Lyons—whose fees were paid by Banks and his fellow-students directly. At Revesby, after forming a friendship with Lord Sandwich (a neighbouring landowner) which was to affect considerably his subsequent career, he devoted himself to botanical studies with such zeal that in 1766 he was elected a fellow of the Royal Society—probably the youngest on record. In the same year he investigated the flora of Newfoundland, and in the following year made the acquaintance of Dr. Solander, a pupil of Linnaeus.

The transit of Venus due to occur in 1769, and the choice of James Cook (q.v.) to take charge of an expedition to the Pacific to observe it, gave Banks the chance of his life. Thanks to his friendship with Lord Sandwich—who was now first lord of the admiralty—he obtained permission to join Cook, and promptly got together a very full equipment for making collections in every branch of natural science, and a staff that included Dr. Solander and four artists. The story of the *Endeavour's* voyage is told under Cook, James and Exploration by Sea. The share of Banks in it was, as might be anticipated, mainly of scientific value, and its immediate result for him was that his university made him a D.C.L. But in the particular episode that is of most interest to Australians he played by far the most important part. Cook, a navigator by profession and instinct, was but slightly interested in the new lands he discovered except in so far as he considered them hindrances to navigation and fresh boundaries of the ocean which was his sphere. 'The discoveries made in this voyage are not great,' he told the admiralty. But Banks never forgot the new southern land. His first impressions, certainly, were unfavourable; 'barren it may justly be called, and in a very high degree . . . . upon the whole the fertile soil bears no kind of proportion to that which seems by nature doomed to everlasting barrenness.' But at that moment he had come from tropical islands, and was going back among tropical islands. Once back in England, the more his imagination dwelt on Botany Bay the better he thought it; and by 1779, when the house of commons was looking for a new location for a convict settlement, he had quite made up his mind that New Holland was worth occupying even in spite of its remoteness. By this time he was president of the Royal Society (elected on 30 November 1778), and a man of note and influence; when, therefore, he in 1779 advocated before a committee of the house of commons the establishment of a penal colony at Botany Bay, in 1783 warmly commended the proposal of James Mario Matra (q.v.) to colonize the country with loyalist Americans and Chinese, and in 1785 backed Sir George Young's revival of the Matra proposal, the British government became slowly convinced that the far-off country must really be of some value; and in 1786 it was decided to send a batch of convicts out as an experiment. When once the settlement was made, Banks (who in 1797 was made a privy councillor) set himself to make it a success by every means in his power. He was constantly consulted by the British government on matters relating to the administration of affairs in the new colony. He had a hand in the appointment of governors; King was his protégé, Bligh his nominee. The arrangements connected with the despatch of Flinders's expedition in the *Investigator* were left in his hands. No better illustration of the trust reposed in him can be exhibited than a slip of paper on which is written—'28th of April 1801—Is my proposal for an alteration in the undertaking of the *Investigator* approved? J.B.' 'Any proposal you may make will be approved. The whole is left entirely to your decision.' The last sentence is not signed, but was probably written by Evan Nepean, secretary to the admiralty. The governors almost invariably maintained a correspondence with Banks, giving him valuable information that was not contained in their official despatches. Hunter sent him specimens of the newly discovered coal. King, while still a minor official, brought him waratahs and Norfolk Island pines. Macarthur sent him fleeces—which he did not think much of. Kent took home for him emus and black swans. He provided the young colony with gardeners and explorers—though Mungo Park was not allowed to try his hand on the Blue Mountains. Robert Brown, George Suttor, George Caley, and Allan Cunningham all were friends and for a time employees of the great man. There is reason to believe that he actually refused high office on the ground that his services would be of more value to the colony if he kept aloof from ministerial responsibility. A memorandum in his own writing runs thus:—'I could not take office and do my duty to the colony. My successor would naturally oppose my wishes. I prefer, therefore, to be friendly with both sides.'

By the time he reached middle age, he occupied a unique position in the scientific and social world of England. He had achieved a reputation for universal wisdom, and was approached for information on subjects as various as hydraulics, tanning, the plucking of geese, coinage, earthquakes, and his pet subject botany. He was a diligent member of the Society of Arts, the Engineers' Society, the Dilettante Society, and the Society of Antiquaries; a founder of the Royal Institution, and a member of the National Institute of France. His active connection with Australian affairs, however, diminished considerably when Macquarie, first of the soldier-governors, initiated the new regime, though he maintained his interest in the country through Allan Cunningham and others, and was entrusted with the superintendence of the draughtsmen and engravers who prepared Flinders's charts, etc., for his *Voyage to Terra Australis.* It was probably a sign of failing energy and growing conservatism that he prevented Flinders from using in that book the name 'Australia' which the author so much favoured, and insisted on the retention of the cumbrous Latinism which disfigures the title. His interests, however, if narrowed in one direction,

widened elsewhere, and he actively promoted explorations in China, Brazil, Sumatra, Egypt and the Congo valley. For at least 14 years before his death he had lost the use of his legs, but continued to preside actively over the Royal Society, and gathered round him such savants as Stamford Raffles, Barrow, Hooker, de Candolle, Humphry Davy and W. E. Parry. On 16 March 1820 he sat for the last time in the chair at a council meeting; on 18 May he offered to resign, but the council refused to let him; on 19 June he died without issue. (Baronet, 1781; K.C.B., 1795.) See OBEREA.

Banksia, a genus of the family Proteaceae, endemic in Australia, containing some 48 species of stunted trees. The flowers are in pairs in dense cylindrical oblong or globular spikes; corolla straight or curved, the slender tube opening equally or along the lower side only, the segments remaining coherent, or rarely separating as the tube opens; anthers seated within the concave segments of the corolla;

Honeysuckle.
(*Banksia collina*)

style longer than the flower; fruit a compressed capsule, opening at the broad end in 2 horizontal valves; seeds 2, compressed, with a terminal membranous wing, broad and rounded like valves; leaves alternate, entire, toothed, or deeply divided. In the fruit the floral bracts become consolidated with the axis of the spike into a thick woody cone. The proportion of perfect capsules to flowers is usually very small. The genus is named after Sir Joseph Banks. The popular name 'Honeysuckle' is generally applied to the Banksias, whose flowers contain honey in considerable quantities; 'Bottle-brush' (a name frequently bestowed on the *Callistemons*) is also in use. *B. ericifolia* would be a useful shelter-tree in low-lying or swampy land. *B. aemula, B. dentata, B. littoralis,* and *B. marginata* have ornamental timbers which are, however, only available in small sizes, and require to be carefully seasoned.

Banksia serrata (Red Honeysuckle), is a gnarled tree reaching 50 feet in height with a trunk diameter of 3 feet, usually growing on poor, sandy soil. The tuberculate, corky bark contains tannin. The timber is a purplish-red with a coarse grain. It is a good working timber, not liable to split with nailing, and is reputed to last well. It is used for window-frames and boats' knees. A dark red gum or resin is obtained from this species; this renders the wood specially useful for camp fires, as it is readily combustible both green and dry.

Banksia integrifolia (White Honeysuckle), is a tree of 40-50 feet high. The specific name implies an entire leaf margin as a distinguishing character; but it is not altogether reliable, as the margins are frequently more or less deeply toothed. It ranges from Victoria to Queensland, mostly haunting the coastal districts, but extending in places to the tablelands. It is capable of withstanding the harsh conditions of the sea-coast, where it frequently forms groves on the dunes, and is valuable for sand-binding and reclamation. The pinkish timber has a neat grain, and is used for boats' ribs and knees. The bark is occasionally used for tanning.

Bannerman, CHARLES, born in Sydney on 3 July 1851 and still living, was one of the most brilliant batsmen ever reared in Australia, though he took part in very few important matches. In the first test match between England and Australia, played at Melbourne on 15 March 1877, he made the first century recorded in test cricket—165 retired hurt: no other Australian batsman made more than 20 in either innings, so that Bannerman's score won the match for Australia, and £165 was collected on the ground and presented to him there and then. As a member of the Australian eleven of 1878—that notable collection of pioneers who laid the foundation of Australia's greatness in cricket—he was the first Australian batsman to score 100 against English bowling in England, a feat which he repeated against local bowling both in the United States and in New Zealand.

His younger brother ALEXANDER CHALMERS BANNERMAN (usually known as 'Alick'), born on 21 March 1857, was a member—at the age of 19—of the same eleven; but his temperament was exactly opposite to that of Charles, and his batting reflected it. He was the greatest stone-waller Australia has known. He visited England with the teams of 1878, 1880, 1882, 1884, 1888, and 1893; he played against England in 28 test matches, scoring over 1000 runs in 50 innings, and thus obtaining an average of 23.08. In those days, it must be remembered, wickets were inferior to those of to-day, and the bowlers Alick had to meet were of a quality no one has ever questioned. His patience was inexhaustible, his defence rock-like, and he invariably went in first for Australia. Perhaps his finest achievement was in the Sydney test match of 1892

against an eleven brought out by Lord Sheffield and captained by W. G. Grace. Going in for the second innings in face of a deficit of 162 runs, he batted for 7½ hours, scoring 91 runs—one of the most valuable innings ever played in a test match. Alick was also a great fieldsman at mid-off.

Charles has frequently officiated as umpire in 'big' cricket, and Alick was for some years official coach at the Sydney cricket ground. Both were shrewd judges of the game and the players, and did yeoman service in helping to develop the skill of a later cricket generation. Alick died at Sydney on 19 September 1924.

See CRICKET. L.O.S.P.

Bannister, SAXE (1790-1877), born at Steyning in Sussex on 27 June 1790, and educated at Tonbridge and Oxford (B.A., 1813; M.A., 1815), during the 'hundred days' of Napoleon's return to France in 1815 raised a company of militia and was given a captain's commission therein. After Waterloo he retired on half-pay and was called to the bar from Lincoln's Inn. When on Bigge's recommendation it was decided to appoint an attorney-general for New South Wales, Bannister obtained the appointment, and reached Sydney on 5 April 1824, bringing with him the 'Charter of Justice' by which the first supreme court was established in the colony. While able and high-minded—Darling, who quarrelled with him, describes him as 'a Philanthropist almost in the extreme, often misled by an injudicious zeal, but indefatigable, conscientious and honorable in the highest degree'—he was inclined to magnify his office and insist upon his personal rights to an extent which antagonized even Brisbane. The clash came when Brisbane ordered him to prepare a bill indemnifying certain magistrates (among them Samuel Marsden and Hannibal Macarthur) for irregularly condemning convicts to floggings, not for crimes committed, but in order to extort confessions of crime or evidence against other convicts. Bannister declared that such a bill conflicted with 'the fundamental law of England' and its draftsman might be exposed to punishment; Brisbane maintained that the attorney-general's opinions were irrelevant and his office in this respect 'merely Ministerial'—i.e. that it was his duty to draft any bill 'which may be required by the Governor with the advice of the Council.' The dispute was remitted by Brisbane to the colonial office for decision: but meanwhile Bannister had been worrying Earl Bathurst with requests for an increase of salary (he was originally allotted £600 with leave to increase to £1200 by private practice, but had little spare time for the latter), the British authorities decided to replace him by a less important official, and Bathurst seized with joy the opportunity of leaving the constitutional dispute undecided.

With the arrival of General Darling (q.v.) there began an era of party quarrels within the framework of the colonial government, John Macarthur with Archdeacon Hobbes Scott, attorney-general Saxe Bannister, surveyor-general Oxley and Dr. Bowman forming a quite definite Opposition in the inner circles. In Darling's eyes, however, Bannister was the least objectionable of the bunch, and several passages in this governor's early despatches show a quite unusual admiration of his character and work. But in June 1826 Bannister refused to sit at Darling's table with Dr. Wardell, who as editor of the *Australian* was bitterly attacking the Macarthur party, and was at the moment receiving Darling's support; and from that time on Darling's adjectives altered. Bannister was now 'eccentric,' 'extremely weak and easily led astray,' so hasty 'that no dependence can be placed on the soundness of his opinions or the expediency of the measures he proposes;' and Darling began to urge on the colonial office 'his unfitness for his situation' and the necessity of appointing a successor at once. In September arrived the despatch announcing the appointment of a successor, and Darling immediately seized the chance of dismissing Bannister and nominating the government solicitor to fill his place pending the new appointee's arrival. The dismissal was followed by press attacks on Bannister's character, one of which, in the *Australian*, was extremely malicious; but Darling refused to prosecute on the ground that the victim was no longer a government official, and Bannister, determined to lay his case before the authorities in London, sailed on 22 October, after fighting on the 21st a harmless duel with Dr. Wardell. His Australian career is chiefly remarkable for the quarrels with Brisbane and Darling; but it must not be forgotten that he founded the first infant school in Sydney, and took an active interest in the treatment of the Australian aborigines by white settlers. During 1827 he was stationed at the Cape of Good Hope, but was recalled to England early in 1828.

After his return to England little is known of his doings, except in so far as he wrote a good deal on legal and historical subjects. The colonial office rejected his complaints about Darling's behaviour, and a later appeal for compensation (in 1853) was equally unsuccessful. In 1838 he helped to found the Aborigines Protection Society; in 1848 he was appointed bedel to the Royal College of Physicians, London, and thenceforth busied himself a good deal with the life and work of William Paterson, the founder of the Bank of England. He died on 16 September 1877, at Thornton Heath near London.

Baptists. The Baptists in Australia hold, numerically, the fifth position among religious denominations. Being congregational in church government, and independent in church polity, their early history must necessarily be a record of individual churches; only in 1858 did these become sufficiently numerous to combine in unions. In 1831 there arrived in Sydney from England John McKaeg (q.v.), a fully accredited Baptist minister, and the Sydney *Monitor* of 27 April announced: 'A Mr. McCabe has commenced preaching in the long room of the Rose and Crown Inn, Castlereagh-street. On Sunday last (24th) a few persons of the Baptist persuasion attended.' Services were subsequently held in a room in King-street, and in a larger room in Hart's Buildings, Pitt-street, where a Church was formed. The first baptisms took place in Woolloomooloo Bay, at the foot of Bourke-street. In September 1832 the governor granted the site upon which the Bathurst-street church now stands. Funds were raised, and building material purchased, but the erection was delayed, and early in 1834 McKaeg resigned. In response to a request made to the Baptist Missionary Society in London, John Saunders arrived on 1 December 1834, and held services in a room in the old court house in Castlereagh-street (which afterwards became the girls' high school); simultaneously the erection of the

Bathurst-street church was resumed, and the church was opened on 23 September 1836 at the modest cost of £1400. The first membership had apparently lapsed, for on 17 November 1836 the Church was again formed; it included several who were not Baptists, and was therefore formed on an 'open membership' basis, but in 1840, after the transfer of several members to the Pitt-street Congregational Church, the constitution was changed to 'close' membership with 'open' communion. Saunders did much to establish the Baptist position before ill-health compelled him to resign in 1847. He was succeeded by John Ham, of Melbourne, who died after four and a half years' ministry. A second application to the Baptist Missionary Society brought out James Voller, who had the misfortune to be shipwrecked on Amsterdam Island, but eventually reached Sydney on 30 December 1853, and exercised his ministry for 17 years. The second Baptist Church was formed at Parramatta in 1851, and was followed by the formation of Churches at Smithfield and Hinton (1857), Newtown (1860), Maitland (1861), Harris-street, Sydney (1862), Bathurst (1863), and Newcastle and Wallsend (1864).

Baptists of the 'strict and particular' order met first in the schoolroom of Joseph Kemish in Macquarie-street, Sydney, and afterwards in Kent-street, under the ministry of Simeon Emery, until in 1858 the congregation of the Goulburn-street church was dissolved, and they occupied that building. Pastor John Bunyan McCure succeeded Emery, and a Church was formed on 4 July 1861. In 1863 the building in Castlereagh-street was erected, and for a period of 21 years was the scene of the labours of Pastor Daniel Allen.

Tasmania claims the second Baptist Church in Australasia. Henry Dowling, a Strict Baptist minister, arrived at Hobart on 2 December 1834, proceeded in February 1835 to Launceston, preached in the court-house, and decided to reside there and itinerate through the island. On 14 June 1835 a Church was formed in the house of W. J. Ware at Hobart; this, with one formed about the same time at Launceston, constituted 'The Particular Baptist Society of Van Dieman's Land' of which organization Dowling became secretary. Land granted for a building at Launceston was sold, and the first church building was erected there on a purchased site in York-street. In 1840 a building was erected in Harrington-street in Hobart. Dowling died in 1869. In 1846 S. Hewlett of Wollongong in New South Wales became pastor of the Hobart Church. A visit from Thomas Spurgeon in 1880 gave a considerable impetus to the work, but the chief advance was due to the denominational loyalty and generosity of William Gibson, his wife and son, of Perth in Tasmania. The benefactions of the Gibson family (including £11,000 to establish a sustentation fund) amounted to almost £70,000.

In *Victoria* Baptists first met in a tent in 1838; services were conducted by Peter Virtue and James Wilson. A Church was formed in 1839, and several persons were baptized on the beach below Emerald Hill. John Joseph Mouritz, who belonged to the Scottish Baptists, arrived in 1840, combined dairying with the ministry, and conducted services in a room in Collins-street where the Victoria coffee palace now stands. This room belonged to Samuel Crook, who came from Sydney, and whose wife was the first person baptized in Melbourne. In 1841 a move was made to Little Collins-street, where Presbyterians had granted the use of a small wooden building. In December 1842 John Ham, whose passage was booked to Sydney, was prevailed upon to stay in Melbourne, and Mouritz in 1843 formed a Church in Fitzroy, where he lived. The site of the Collins-street church was then secured from the government, and the opening services were held on 28 December 1845. Ham left for Sydney in 1848, and was succeeded by J. Taylor, J. Martin, and (in 1877) Samuel Chapman.

In *South Australia* the first Baptists to settle were W. Finlayson and his wife in 1837. They were joined shortly afterwards by David Maclaren, manager of the South Australian Company. In July 1838 13 Baptists met in Finlayson's house and formed themselves into a Church, and on 2 September they began services in a schoolroom that had previously been the banking office of the South Australian Company. D. Maclaren (father of Dr. Alexander Maclaren of Manchester) conducted the meetings, but declined to accept the pastorate. In 1839 a removal was made to a building previously used by Wesleyans; and after some vicissitudes a new congregation was formed and a building opened in Franklin-street on 4 January 1846. Meanwhile in 1843 a Church had been formed in North Adelaide, and a building erected in Kermode-street, under the pastoral care of James Allen; this was used until his departure in 1846. A Church was also formed in 1843 at Gumeracha under J. P. Butterfield. In 1847 George Stonehouse re-formed the Church in Kermode-street, which was occupied until a new building was opened in Lefevre Terrace in 1850. The most powerful influence upon Baptist life in South Australia was exercised by Silas Mead, who arrived in 1861, formed a Church in Flinders-street, and ministered to it for 34 years.

Baptists in *Queensland* were much indebted to the immigration scheme of Dr. Lang (q.v.). Adherents of the Presbyterian, Congregational, and Baptist denominations, being too few to establish separate churches, joined in a 'United Evangelical Church' with Charles Stewart, who had come out by the *Fortitude* in 1849, as the first minister. A building was erected in William-street, Brisbane, where the executive building now stands, and it was provided that, when the various denominations felt sufficiently strong to separate, this building should be sold and the proceeds divided between them. On 5 August 1855, the Baptists resolved to form a separate Church, and (Stewart having returned to England) invited Charles Smith of Sydney to the pastorate. They first met in the old police court, and afterwards in the old supreme court, Queen-street. As a number of Congregationalists desired association with them, the Church adopted the 'open membership' basis, but on the formation of a Congregational Church this was changed on 20 April 1857, to 'close' membership and 'open' communion. When Smith left Brisbane, the Church appointed as pastor one of its foundation members, R. A. Kingsford. In June 1857 J. Voller of Sydney visited Brisbane, exciting much enthusiasm, and baptizing in an open water-way near the present Roma-street markets George and James Grimes, members of a family of staunch Baptists who had come out under Dr. Lang's scheme. On Voller's advice the Church applied to the Bap-

tist Missionary Society, and B. G. Wilson arrived on 12 September 1858. The William-street building having been sold for £1500, the Baptists received about £500, purchased a site in Wharf-street, and erected a stone building at a cost of £2050. At the opening service on 6 February 1859 Wilson baptized 20 persons. The second Baptist Church was formed at Ipswich. Samuel Welsby, a teacher who arrived in the *Fortitude*, commenced there services which resulted in the formation on 17 March 1853 of a Union Church with Thomas Deacon, a Baptist, as its first pastor. In the following year a Congregational Church was formed, and according to arrangement Deacon retired, but in January 1860 he became pastor without emolument of a Baptist Church then formed. It met first in a bowling alley, but a small church was soon erected in West-street; Deacon died on the day of its opening. 'Jireh' Church in Fortitude Valley was formed on the 'strict' basis on 2 December 1861, with John Kingsford as honorary pastor. In Rockhampton two earnest Baptist brothers, W. H. and C. H. Buzacott, started the first newspaper in that town. After a visit from B. G. Wilson, services were started in W. H. Buzacott's house, and on 25 January 1862 a Church of seven members was formed.

Western Australia was the last Australian colony to establish a Baptist Church. Services had been held in Perth by George Johnson, but no Church was formed until after the arrival from Victoria of J. H. Cole, who held meetings in Perth town hall in October 1894. Churches were formed at Fremantle in 1895 and at Katanning in 1896, the first building being erected at Bayswater in 1896. Cole returned to Victoria, and was succeeded by A. S. Wilson, a young man of unbounded enthusiasm, under whose ministry much progress was made, and the building in Museum-street was opened on 5 May 1899. As Wilson felt constrained to advocate 'open' membership, a Church on 'close' membership lines known as the North Perth Baptist Church was formed under the leadership of J. W. Jaques as honorary pastor.

A Baptist Union is on a voluntary basis, and possesses no legislative authority except by agreement among the component members, but the desire for fellowship and for the extension of the Kingdom of God invariably leads to steps for the close association of Churches of the same faith and order. Thus on 20 July 1858 a meeting held in the vestry of the Bathurst-street church in Sydney decided to form an Association of Baptist Churches, and drafted a basis. On 21 September the first meeting was held at the same church, delegates from the Bathurst-street, Parramatta, Hinton, and Smithfield Churches being present. A 'Colonial Missionary Society' was formed for home mission work. For some reason the association lapsed, but ten years later, after an address by Pastor D. Allen in the Castlereagh-street church, J. H. Knibbs on 27 December 1867 convened a meeting in his own house; a further meeting on 3 January 1868 was attended by representatives of three Churches, but two only (Masonic Hall and Newtown) formed themselves into an Association, framed a draft constitution, and appointed Allan W. Webb secretary. The first official meeting was held on 11 February in the Castlereagh-street church. Delegates present represented four Churches, and three others were affiliated, but for various reasons some Churches did not immediately seek admission. On 20 January 1869 the Association comprised 11 Churches and 359 members, and at the third annual meeting on 19 January 1870, 18 Churches were represented—all there were in the colony except the 'strict' Churches. The name was then changed to 'Baptist Union of New South Wales.' Steps were at once taken to educate young men for the ministry, and to organize a preachers' society and an auxiliary of the Baptist Missionary Society. In 1871 the Colonial Missionary Society mentioned above was merged in the New South Wales Home Mission Society. A resolution was carried 'to secure the co-operation of all the Colonies in some common plan of action by means of an Australasian Baptist Union.' In 1872 a resolution was carried, on the motion of James Greenwood, then pastor of the Bathurst-street Church, 'That the Baptist Union protests against the extension of Denominational Schools at the expense of the State, as being another form of State Endowment of religion.' Greenwood is understood to have been the real father of the New South Wales education act passed in 1880 by Sir Henry Parkes.

Unions with similar objects and methods of operation were formed in other colonies—Victoria in 1862 (comprising 10 country and 6 city Churches), South Australia in 1863 (with about 12 Churches), a Northern District Association in 1884, Queensland in 1877 (with 7 Churches), Tasmania in 1884 (with 8 Churches), and Western Australia in 1896 (with 4 Churches).

Some of the early Churches displayed remarkable zeal, their members travelling widely and holding meetings in cottages and public buildings. With the formation of Unions the organization of home missions became specially important. Mention has been made of the Colonial Missionary Society in New South Wales, and in 1872 the Union directed the New South Wales home mission 'to aim at the establishment of a Christian Church in every centre of industry throughout the colony.' But the Churches were few and small, and a marked development did not occur until the superintendent, A. J. Waldock, was set free in 1908 to devote his whole time to the work. More than half the Churches in New South Wales owe their origin to home mission enterprise. In Victoria a society was formed in 1871, but made little progress until the appointment of F. J. Wilkin as superintendent in 1893. In South Australia the Union was practically a home mission society, and its formation initiated the expansion of the Baptist cause. The same may be said of other States.

Unions having been formed at a time when great interest was being displayed in foreign missions by Baptists in England, it was natural that Baptists in Australia should contribute to the funds of the missionary society in London. Silas Mead was an enthusiast for foreign missions, and on 10 November 1864 called a meeting at the Flinders-street church in Adelaide, at which it was unanimously agreed to organize a South Australian Missionary Society. At first the committee sent money to India for the support of native missionaries; but in 1865 J. C. Page, from India, who visited Australia in search of health, met the recently formed society, and urged that it should take up a definite mission-field, offering to give partial oversight to such a field in Bengal. Faridpur in eastern Bengal was selected, and the committee guaranteed £100 a year for the support of four native preachers and a schoolmaster. In 1881 two Australian ladies, Marie Gilbert and Ellen Arnold, offered for zenana work, and in October

1882 left for India. Two years later Miss Arnold had to return through serious illness. Recovering her health, she proceeded as missionary evangelist to all the Australian colonies except Western Australia; her advocacy greatly stirred the Churches, and she took back other workers on her return to Bengal in 1885. The mission house at Faridpur became a general training school for missionaries who there acquired the language and went to other districts in eastern Bengal. The foreign mission workers were the first to realize the advantages—and the urgency—of united effort, and after steadily increasing co-operation complete federation took place in 1922. The Australian board of Baptist foreign missions has its headquarters in Melbourne, with branches and committees in every State. Ten districts in eastern Bengal are occupied, with eight out-stations. Australian missionaries and wives number 37, with 22 native preachers, 12 colporteurs, 11 Bible women, a Church membership of 1988, and a Christian community of 4166. The foreign mission estimates total about £16,000 yearly. A monthly journal, *Our Indian Field*, circulates among the Australian Churches.

The work of home missions involved the training of young men for that ministry, and as early as 1871 a Baptist educational institute was formed in New South Wales and classes started under the direction of James Greenwood. Similar steps were taken in other colonies. In Victoria in 1884 an anonymous donor offered £25,000 conditionally upon the raising of a similar amount. This 'Victorian Baptist Fund' was to be used (*a*) for the establishment and maintenance of a college for training students for the ministry, (*b*) for a church loan and building fund, (*c*) for a ministers' sustentation fund, (*d*) for an aged ministers' fund. Under the leadership of Samuel Chapman the Churches accepted the offer, and the fund was completed in 1886, the Jubilee year of Victorian Baptists. The fund now amounts to £78,000. In accordance with its objects a Victorian Baptist college was established, with Dr. W. T. Whitley as principal, and started work in 1891; in 1911 W. H. Holdsworth became principal. At first students from other colonies, especially from New South Wales, took advantage of the college; but it was found that the terms of the trust did not permit non-Victorian students to receive pecuniary advantage, so in 1916 a college was established in New South Wales under Principal Alexander Gordon, who resigned in 1920 and was succeeded in 1921 by G. H. Morling. The South Australian Union has a mutual arrangement for educational purposes with the Congregational Union, and Queensland utilizes the services of ministers holding pastorates. In most States some subjects are studied at the local university, and others in conjunction with the colleges of other denominations. Victoria leads the ways in secondary school education, the Carey grammar school having been opened in 1923; it possesses a fine property at Kew.

The Victorian Baptist Fund included an aged ministers' fund, the capital of which now stands at £11,000. In New South Wales a fund, established in 1900 by the generosity of Hugh (afterwards Sir Hugh) Dixson, has a capital of £12,250. South Australia has a contributing fund, with a capital of about £12,000. In Queensland the fund has reached only £500. Western Australia has a capital of £1500. The basis of the South Australian fund is regarded as the most suitable for all the States, and resolutions carried by the congress (see below) recommend other States to adopt a similar basis, so that the removal from one State to another will not deprive any minister of the advantage of the fund; but the terms of the different trusts present serious difficulties. Loan and building funds for the assistance of Churches exist in most of the States.

The desire for federation found early expression, but the most important step in that direction was the holding of the first Australasian Baptist congress in 1908 in Sydney. The second was held in Melbourne in 1911, but owing to the war the third was not held until 1922. One result already mentioned has been the federation of foreign missions. A weekly paper, *The Australian Baptist*, which first appeared in 1912, took the place of monthly papers published in each State, but after several years the monthly papers were resumed in all States, being supplementary to the *Baptist*. At the third congress a first step was taken towards inter-State home missions, and the forming of an Australian Baptist Union has been considered. Business between meetings of the congress is carried on by an inter-State board, with representatives in each State.

In the census of 1921 105,703 persons enrolled themselves as Baptists. In association with various Unions there are in New South Wales 76 Churches, 72 ministers and home missionaries, 6469 Church members, and 8300 Sunday-school scholars. In Victoria the figures are 90, 89, 7419, and 10,688 respectively; in South Australia 80, 57, 5148, and 7699; in Queensland 46, 34, 3468, and 4937; in Tasmania 18, 20, 1407, and 2167; and in Western Australia 27, 17, 1175, and 1607. The totals for Australia are 336 Churches, 292 ministers and home missionaries, 25,086 Church members, and 35,398 Sunday-school scholars. There are also a large number of preaching stations connected with the Churches.

W.H.

Barff, Henry Ebenezer (1857-1925), born on Tahiti in the Society Islands on 9 July 1857, was brought by his parents to Australia in 1865 and educated at the university of Sydney (B.A., 1876; M.A., 1882). In 1876 he was appointed a master of studies at the university, in 1878 a mathematical lecturer, and in 1880 acting-registrar. In 1882 this appointment was made permanent, and in 1914 was dignified for him with the additional title of 'warden.' His life was thus bound up with the university, of which he was for many years the senior and the most experienced official, the guide of four chancellors, 11 vice-chancellors, and numberless professors. In his time the institution grew from a body of four professors and about 50 students to one of nearly 250 teachers and staff with over 5000 students. In November 1922, worn out by the strain of administration during the war and the period of over-crowding that followed it, he offered to resign; refusing the offer and granting him instead long leave of absence, the senate by resolution attributed to him 'such performance of duty as places him historically among the chief makers of the university, and will remain its model of highest executive capacity and achievement.' On 31 August 1924 he retired from all active work, and died at Sydney on 2 May 1925. His only written work is *A Short Historical Account of the University of Sydney*, published in 1902. (C.M.G., 1923.)

Barker, COLLETT, entered the army in 1806 (ensign, 1806; lieutenant, 1809; captain, 1825—all in the 39th regiment), and during 1828 joined his regiment in Sydney, being sent away almost immediately to take over the establishment at Raffles Bay in northern Australia from his fellow-officer George Sleeman, who had been transferred to King George's Sound. Reaching the Bay on 13 September, he worked hard to ensure the health of the settlement and to conciliate the neighbouring aborigines, who had been always hostile to the settlement and in 1827 had come into collision with the garrison. Barker established his reputation with Darling by his handling of both these problems, and was able in February 1829 to report both that the garrison was healthy and that the blacks were friendly and frequent visitors. He deprecated the despatch to the Bay of soldiers 'under 25 years old or of a weakly, scrofulous or indolent habit.' In February he received the personnel and stock of the Melville Island settlement, which the British government had decided to abandon; in July he was ordered to abandon Raffles Bay also, transferring the settlement to King George's Sound. This decision, he thought, was unfortunate, as in March, April, and May the Bay had been visited by a large number of Malay fishermen and traders from Macassar; the Dutch governor of that place and the visitors themselves had been delighted to find a permanent British settlement so handy to their trepang fishing grounds, and its premature abandonment was disappointing and disadvantageous.

On 28 August Barker sailed from the Bay, leaving a flag flying at the fort there, and proceeded via Kupang and the Swan River to King George's Sound, where on 3 December he again succeeded Sleeman as commandant. His tenure of command there (which was praiseworthy but uneventful) ended in January 1831, when the colonial office decided to place the Sound under Stirling, then in charge of Swan River. Darling at once arranged to make Barker Resident at the Bay of Islands in New Zealand, where his known ability for handling uncivilized tribes would make him a valuable intermediary with the Maoris. But on his way back from the Sound Barker by instructions landed in April at the mouth of the Murray, to discover whether any communication existed between Lake Alexandrina and the Gulf of St. Vincent. Finding none, he swam the mouth of the river with the intention of trying to find some better outlet from the lake to the sea, disappeared over a sandhill, and was never seen again. It was afterwards ascertained that he had been speared by natives. Barker's zeal and ability were warmly praised both by Darling in a government order and by Goderich, then colonial secretary, in a special despatch of 24 December 1831.

Barker, FREDERICK (1808-1882), born at Baslow in Derbyshire, England, on 17 March 1808, was educated at Jesus College, Cambridge (B.A., 1831; M.A., 1839), ordained in 1831, and spent three years as curate of Upton in Cheshire. From 1835 to 1854 he held the living of St. Mary's at Edgehill near Liverpool, and in 1854 was transferred to Baslow, but in August Archbishop Sumner chose him to succeed Dr. Broughton as bishop of Sydney and Metropolitan of Australia. Consecrated on 30 November 1854 and made D.D. *per literas regias*, he reached Sydney on 25 May 1855. As metropolitan he found four dioceses besides his own—Tasmania, Melbourne, Adelaide, and Newcastle—under his jurisdiction: to these during his primacy he added Perth (1856), Brisbane (1859), Goulburn (1863), Grafton and Armidale (1866), Bathurst (1869), Ballarat (1875), and North Queensland (1878). The system of state aid for religious denominations, which had been in existence since the early days of the settlement, was abolished in 1863—except to the then recipients—by a 'Grants for Public Worship Prohibition Act,' and Barker at once set about the preparation of a constitution for the Church of England in Australia. In 1866 he secured the passing of an act to give the Church power over its own property, and on 5 December of that year was in consequence able to preside over the first diocesan synod of Sydney. He succeeded further in establishing a general synod of the whole Anglican Church in Australia, which met three times during his primacy. In his own diocese his unceasing work was of the greatest value; St. Andrew's cathedral was completed and consecrated, rural deaneries were established, Moore College was founded at Liverpool, New South Wales, for the education of candidates for holy orders, a church buildings loan fund and a Church Society were formed, and the work of the parochial clergy was made easier and more effective both by the primate's intimate supervision and encouragement and by the financial assistance which he procured from the laity. During his episcopate 236 churches were erected in the diocese. In 1881, being attacked by paralysis, he visited England and the French Riviera, but died at San Remo on 6 April 1882. See CHURCH OF ENGLAND.

Barkly, SIR HENRY (1815-1898), was the only son of Aeneas Barkly, a West India merchant, and on leaving school entered his father's business. In 1845 he was returned to parliament as member for Leominster, but in 1848 took the governorship of British Guiana, where he had large estates, and began a career of nearly 30 years as professional governor—of Jamaica 1853-6, Victoria 1856-63, Mauritius 1863-70, the Cape Colony 1870-7. It is not easy to understand why he was appointed to Victoria, as his special qualification was an intimate knowledge of the requirements and conditions of coolie labour which made his terms of office in Guiana, Jamaica and Mauritius particularly valuable: but his Victorian career, which coincided with the first seven years of the 'responsible government' regime, was markedly successful, partly because he followed a governor (Sir Charles Hotham, q.v) who had seemed to leading colonists deficient both in social qualities and in economic and constitutional knowledge, partly because he handled with sagacity and tact several important constitutional problems which were bound to crop up at the beginning of the new regime. The experience he gained in Australia proved extremely useful when at the Cape of Good Hope he again found himself helping to introduce responsible government, and at the same time being pressed by an over-enthusiastic secretary of state to force a system of federation on the South African colonies.

From the personal point of view Barkly's governorship is chiefly notable for his political self-effacement; he was in that respect the beau-ideal of a constitutional governor. It was also a remarkably progressive epoch in the history of Victoria; it included the construction of the first two main railway lines—from Melbourne to Bendigo and from Geelong to Ballarat—the des-

patch of the Burke and Wills (q.v) exploring expedition, drastic reforms in the prison system, the founding of the national art gallery and the national museum, and the establishment in Melbourne of permanent gas and water supplies. In all these matters Barkly was much interested, and his active support appreciably aided their completion. Gyles Turner describes him at this time as follows:—'A tall, handsome man, of cultivated tastes, with a considerable store of scientific knowledge and a thorough grounding in the principles of political economy and constitutional law . . . . His services were always readily available in public movements having philanthropic aims . . . . and his speeches on such occasions were invariably thoughtful in substance and happy in form.'

At the close of his term at the Cape he retired on a pension, and spent the remainder of his life in literary and scientific pursuits. In 1864 he had been made F.R.S., and in 1870 F.R.G.S.; and during eight years of his retirement he took an active part in the administration of the latter society. He died in London on 20 October 1898. (K.C.B., 1853; G.C.M.G., 1874).

Barley. The production of barley within the Commonwealth fluctuates considerably from year to year; thus in the five seasons 1916-21 the acreage under crop varied from as low as 205,000 acres to as high as 335,000, while the yield per acre varied from 16 to 21 bushels. Since 1914 South Australia has been the chief barley-producing State. Ninety per cent of its yield is used for malting, but in Victoria, which has the next highest yield and acreage, little more than half the crop is thus used. The Queensland figures are usually almost negligible (though their variation is extreme) and those of the other States taken together show barely an eighth of the South Australian yield. The greater part of the crop supplies the home market; small quantities are exported to the Straits Settlements and to New Zealand. Malting barley is in normal years entirely consumed at home; but in 1917-8 (during the stress of the German submarine campaign), and in 1920-1, a good deal was exported to Japan, the Philippines and South Africa. During the last two years for which figures are available (1921-2 and 1922-3) the average yield for the Commonwealth was 6¼ million bushels (5 millions malting) from about 325,000 acres; of this crop about 2,100,000 bushels were exported. These figures do not include the acreage grown for hay and green forage.

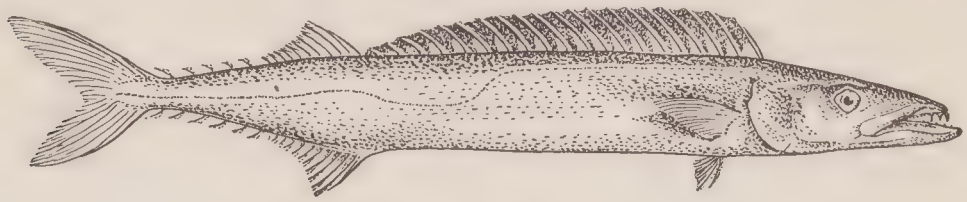
W.S.C.

Barney, GEORGE, (1792-1862), born in London on 19 May 1792, entered the army when only 16 (2nd lieutenant, 1808; 1st lieutenant, 1809; 2nd captain, 1813; 1st captain, 1825; lieutenant-colonel, 1840), and served in the garrison of Tarifa (1811) and at the taking of Guadeloupe (1815). Then for nearly 20 years he was attached to a detachment of engineers in the West Indies, and rose to command it. Employed for a short time on improving the defences of Portsmouth, he was in July 1835 chosen to inaugurate a new system of public works construction in New South Wales. Up to that time all public works in the colony had been designed and constructed in a somewhat haphazard fashion, under the supervision of such persons as the local authorities might think expert enough: but in 1834 Governor Bourke, confronted with the need for more elaborate harbour works at Sydney and Newcastle than had hitherto been found sufficient, proposed the appointment of a civil engineer. The British government had already decided to station in New South Wales a branch of the ordnance department to construct and control buildings belonging to the military or the convict department, and soon afterwards chose Captain Barney for the command of this branch. Early in 1836 Bourke suggested that Barney should also undertake the duties of civil engineer, and arranged with him in advance to clear a channel in the Parramatta River and inspect the Newcastle breakwater: in February 1837 he added to this list the construction of the series of wharves in Sydney Cove now known as Circular Quay, the formation of pier harbours at Wollongong and other coastal ports, and the general supervision of roads and bridges. Approval was reluctantly extorted from the department in London, but Barney took over the work Bourke asked of him without waiting for approval, and even busied himself with the building of an engine for a North Shore ferry-boat. At the same time he devised plans for 'putting the Principal Seaports of this Country in a State of Defence against desultory attacks from Foreign Cruisers.' In the colony, it should be noted, he was always known officially as Major Barney—probably to give him precedence over captains in the infantry regiments stationed there—although in the royal engineers of those days the rank of major was unknown. He designed the Victoria barracks at Paddington, Sydney, and was first chairman of the Australian Gaslight Company. In April 1844 he returned to England in order to take over the engineer command at Woolwich; but when Gladstone determined to establish a new colony in North Australia he chose Barney—probably as a man used to rule, who knew something both about Australia and about convict discipline—for the colony's first lieutenant-governor. Appointed on 25 May 1846, Barney reached Sydney on 15 September, and almost at once set out in the little *Cornubia* to examine the coast-line of his new domain, which commenced at lat. 26° S. The story of his selection of Port Curtis and of the settlement which he began to found there is told under GLADSTONE COLONY. When Earl Grey, succeeding Gladstone as colonial secretary, reversed his decisions and ordered the abandonment of the colony, Barney returned to his position at Woolwich, but soon retired from the army, came back to New South Wales, and on 1 January 1849 was made chief commissioner of crown lands. In October 1851 he became a member of the legislative council, but retired on the introduction in 1856 of responsible government. He was surveyor-general from 11 October 1855 to 13 August 1859; resigning that post, he lived in Edward-street, North Sydney, until his death on 16 April 1862.

Barracouta, a southern circumpolar fish (*Thyrsites atun*) occurring in the waters of New Zealand, Tasmania, and southern Australia, South Africa and South America; it occasionally ranges northwards to the latitude of Port Jackson. It is very elongate (sometimes four feet in length), with flattened sides and a large oblique mouth armed with powerful teeth. Its colouring is brilliant silver on the sides and steel-blue on the back, while the dorsal fin is ornamented with a broad black margin. The name 'barracouta' is a corruption of that of a West Indian fish, the barracuda—a very different species, allied to the Sea-pike (*Sphyraena*) of Australian waters. Bar-

racouta provide fine sport for fishermen, who catch them with a large hook concealed in a brightly coloured rag and trolled behind a boat. They are commonly infested with round-worms, which at times almost completely fill the intestinal tract. These do not affect the value of the fish as food; but it is not regarded as a high-class fish even when in its best condition, though smoked barracouta finds a ready sale in the markets.

The King Barracouta (*Jordanidia solandri*) was first discovered in New Zealand waters by the naturalist Charles Solander, who accompanied Cook on his first voyage to Australia. It was among a number of fishes purchased from the Maoris, and, being three feet in length and obviously good eating, was served up with the rest to satisfy the demands of the ship's company for a variation of their diet of pickled pork. Before reaching the cook's hands, however, it was carefully described by Solander, in a note-book which was later deposited in the British Museum. His manuscript notes were subsequently examined by Cuvier and Valenciennes, who recognized the affinities of the fish with the rare gempyllids, and therefore named it *Gempylus solandri*. The



Barracouta.

species was not again recognized until 1882, when it was taken in Tasmanian waters in great abundance; it was afterwards found off the southern coasts of Australia and in New Zealand waters; a very similar species was obtained in Japan, and its genus was named *Jordanidia* after the greatest of modern ichthyologists, David Starr Jordan. The king barracouta is an excellent food-fish, and may attain a length of three feet, though its usual size is considerably less. It occurs in shallow waters on the cooler Tasmanian coasts, but descends to a greater depth as it extends northwards, being trawled in over 100 fathoms off Port Jackson. It is commonly known in Tasmania as 'kingfish.' A.R.McC.

Barrallier, Francis Luis (1773-1853), of French descent but son of a surveyor in the service of the admiralty, was born in 1773 and while still a young man attracted the attention of C. F. Greville (a prominent politician of the day), who in 1799 recommended the Duke of Portland (then secretary for the colonies) to make him deputy-surveyor-general of New South Wales when that office should become vacant. Portland refused to commit himself in advance, but suggested that Barrallier should proceed at once to the colony so as to be on the spot. Accordingly he sailed with King in the *Speedy*, reached Port Jackson on 15 April 1800, and on 2 July in a general order issued by Hunter was commissioned ensign in the New South Wales Corps; the commission was dated 14 August. His work, however, was concerned with scientific rather than with military tasks; his first job was the designing of a building for the Parramatta orphan asylum, and in March 1801 he was sent with Grant in the *Lady Nelson*, nominally as officer commanding a small guard, but really to help Grant in surveying harbours, etc.; the charts then made of Jervis Bay, Western Port, and Bass Strait (from Cape Northumberland to Cape Howe) were mainly or entirely Barrallier's work. In a second trip (June-July) he mapped the Hunter almost up to Greta and the Williams almost to Dungog. It is remarkable that in his maps the name 'Hunter' is given to the Williams, the Hunter above Raymond Terrace being called 'Paterson.' In recognition of his services King made him engineer and artillery officer of the corps. In October 1802 an unfortunate misunderstanding between King and Paterson led to the temporary withdrawal of Barrallier from all but military duties; King, however, who was planning an exploration of the ranges west of the Nepean and needed Barrallier for it, solved the difficulty by appointing him on 18 October 'aide-de-camp to the governor,' so that his duties were thenceforward fixed by King and not by Paterson. Of the explorations he then undertook an account will be found under Exploration by Land; for many years it was believed that he had crossed the main range and discovered some tributary of the Lachlan, but it is now known that he never crossed the watershed, though he reached it. During his Sydney career he also designed a fort on Observatory Hill which is now the signal station, and made the plans for the first vessel built in Sydney (see Shipping).

But in spite of King's subterfuge Barrallier found the divided allegiance irksome, and in May 1803 resigned his commission in the corps and returned to England in H.M.S. *Glatton*, sailing on 17 May. Thenceforward he followed the regular course of a regimental career (lieutenant, 1805; captain, 1809; major, 1831; retired on half-pay, 1833; brevet lieutenant-colonel, 1840), but was for the most part employed on survey and engineering work, chiefly in the West Indies. From 1812 to 1817 he was employed on an elaborate survey of Barbados. After retirement from the service he settled in London, and died there on 11 June 1853.

Barramundi, a remarkable fish (*Scleropages leichhardti*) first discovered by the explorer Leichhardt in the Burdekin River, Queensland. It is remotely related to the herrings, and is of very ancient lineage, belonging to the family Osteoglossidae, which comprises a small group of freshwater fishes from South America, Africa, Malaysia, and northern Australia. To the same family belongs the great arapaima of Brazil, the largest of freshwater fishes; this attains a length of 15 feet and a weight of over 400 pounds, and is highly valued as food. The Australian fish does not grow above three feet in length, and its dry flesh is so beset with a wall of needle-like ribs as to be scarcely worth the trouble entailed in eating it. The body is greatly compressed, and the head is covered with large flat plates, whereas the scales are very large and thick.

The name barramundi is applied in Queensland to several of the larger freshwater fishes, and in particular to the present species, the Giant Perch (*Lates*) and the Lung-fish (*Epiceratodus*). 'Burramundi' and 'barramunda' are variant spellings. A.R.McC.

Barrier Reef, THE GREAT. Perhaps the most remarkable geographical feature of Australia is the Great Barrier Reef, the largest deposit of coral in the world (the next in size being the Barrier Reef of New Caledonia). Between the extremes of Bramble Cay and Lady Elliot Island, from 9° S. lat. to 24° S. lat., the Barrier Reef stretches 1200 miles. Towards the north it hugs the shore almost within sight of land, but its southern section slants seaward till it is 150 miles away. It is probably built along a foundered coast-line, for beyond it the sea-floor suddenly plunges to great depths, while within it the water is only a few fathoms deep. Northwards its margin is composed of banks a few miles in length, separated by intervals of a mile or so; only a few (the broader) of these channels are charted. As it extends into southern latitudes, the lower temperatures become less and less favourable to coral growth, so that it gradually breaks up into small scattered clusters of reefs, the last of which nearly coincides with the tropic of Capricorn.

The whole of this area is notorious for the dangers and difficulties that beset shipping. Hurricanes occur as far south as latitude 16°, and few summers pass without disaster to vessels and ports. The northward-flowing tide, once inside the line of reefs, is squeezed between them and the mainland till it reaches heights unknown farther south; at Broad Sound, for instance, the spring tides have a range of 30 feet. As the Barrier Reef draws in towards the land, the ship-channel becomes increasingly narrow and crooked; between Cooktown and Thursday Island the route is so difficult that it can be navigated only by day, and under the guidance of a pilot. On the other hand, the outer reefs act as a huge natural breakwater to shelter the coastal waters. From the deck of a vessel within the Barrier the tremendous surf on the outside edge is a magnificent spectacle. Far out of sight of land, and with no apparent cause, a line of boiling surf springs suddenly out of the blue ocean, and runs from one horizon to the other as an unbroken ribbon of dazzling foam. The space between the mainland and the outermost reefs is thickly strewn with islands of two types. In the first group are the coral islets or atolls, whose recent formation can be recognized, as far away as they are visible, from their flat contour; of the other type are the lofty mountain islands of granite or palaeozoic rock, fragments of a former coast-range which existed when the land stood at a higher level. Their chain extends so continuously that for several hundred miles each is in sight of at least one other. Often they are grouped in clusters, some rocky and barren, others clothed with forests of pine and palm. It is islands of this type that make the beauty of the Whitsunday Passage and the Hinchinbrook Passage, winding channels regularly traversed by coastal steamers that pass under towering peaks, among a maze of islets and harbours, where streams cascade through tangles of green foliage to beaches of yellow sand.

The Great Barrier is not a single reef, but an aggregate. The individual reefs that compose it are coral banks of all shapes and sizes—submerged, awash, or topped by a pile of sand, shingle and shrubbery. So inaccessible are these reefs that ordinary travellers or residents on the mainland never see them. Along the actual coast-line the sea is too much muddied with the discharge of rivers to be endured by the coral, which luxuriates in the clear warm water several miles off shore. This, indeed, may be one explanation of the seaward slant already referred to; it is the outflowing waters of the Herbert, Burdekin, and Fitzroy that push the reefs farther away from dry land. When a reef is neared, the first indication of coral may be the appearance on the horizon of a long, low, level block, representing an islet, often covered with plant life. If the reef be covered at high tide, the roar of the surf on the windward side calls a warning. On the sheltered side a sudden change occurs in the colour of the water, from deep dark-blue to vivid emerald-green. It is this change of colour that gives the watchman at the masthead his best warning of a coral shoal-patch. The exposed side of a reef is studded with storm-tossed lumps of coral, varying from the size of a table to that of a haystack, the taller projecting even at high water. At a distance these 'negro-heads,' as they are called, are magnified by mirage, and look like tombstones in a cemetery.

Earlier writers represented a coral reef as resulting from the intelligence of the coral 'insect,' that planned its reef as a bee might construct its honeycomb. Actually the coral animal is a polyp, not an insect, and is not intelligent. It is an animated piece of jelly, which only differs from the sea-anemone by unconsciously forming lime as the human body unconsciously forms bone. Indeed, the animal contribution to a coral reef is chiefly the production of the raw material, lime; the shaping into reef form is mainly done by the mechanism of wind and waves. A reef is not exclusively composed of coral; it is rather a framework of coral, in which all manner of other animals and plants occur. Only at the lowest spring-tides are the fields of living coral exposed to the air. At other states of the tide the living edge of the reef, as seen from a boat through clear water, is a wonderful sight—a sort of landscape whose brilliantly-coloured vegetation has been turned to stone. The coral masses assume the aspect of tufts of heather, or of gigantic mushrooms, or of elegant vases. A general tone of browns or yellows is brightened by dashes of vivid blue or orange, pink or purple. Instead of soft green foliage, there are strewn among the coral endless varieties of animal life, many quaintly shaped and richly coloured. Here and there are giant clams, said to be capable of breaking a man's leg. At low-water the clams gape, and display myriads of eyes like golden beads set in plush or velvet. Sea-urchins are there, with sharp, poisonous spines as long as knitting-needles. There are starfish of many forms, a common one being sky-blue; others have long snake-like arms that writhe about. If one of these be handled, it throws off first one arm and then another till it is completely dismembered. There is a huge brown sea-anemone as big as a dinner-plate, whose broad bosom is the refuge of a small fish coloured brilliant scarlet with a white bar. Lying on the sand in shallow pools are many kinds of bêche-de-mer; in shape like a great sausage, in colour black, brown or yellow, they spread their circle of feelers, and mop up and swallow indiscriminately a mass of sand and weed on the chance that it may contain food.

That part of the reef which is exposed by ordinary tides is not beautiful at all. It consists of banks of sand and piles of dead, discoloured and broken coral. Every storm tears off masses of coral from their roots, flings them on the beach, and grinds them to sand—the sand of such a beach is yellower than ordinary sand, because of the multitude of foraminifera it contains. The beach is often paved with slabs of coral-sand-rock, the petrified core of a former sand-heap. After the wind has sifted and stacked the sand, rain dissolves lime from the surface strata and, re-depositing it farther down, cements the loose grains into solid rock. When another gale strips the cover, stone has replaced the sand. New land is made when sand and shingle are piled high enough to be dry at high tides. Drift or bird-carried seeds take possession, and the spot grows green with shrubs and herbs. The drift flora of a coral strand is a peculiar assemblage, unknown elsewhere, of plants of any kind whose seeds, immune to the poison of salt, are adapted for flotation. As soon as shelter from the surf is obtainable, a colony of mangroves rises from the mud on tall stilt roots. The sand-beach is fringed with a screen of slender willowy *Casuarina*. Over the scorching sand, just out of reach of the waves, trail the long vines of an *Ipomoea*, with a large red flower and leaves shaped like a cloven hoof. The quaint *Pandanus* bears fruit like a wooden pine-apple, and tufts of long, saw-edged leaves set in screws. *Tournefortia* has a round top of beautiful silvery foliage, and the Queensland laburnum decorates the beach with clusters of bright yellow blossoms. The one tree that the visitor expects to find on a coral island—the coco-nut palm—is never seen in this region, except where it has been introduced. Towards the interior of the islet there is often a dense, cool forest of low trees. A sand-bank thrown up four years previously was found by E. J. Banfield (q.v.), a resident on one of the inner islands, to support more than 40 different kinds of herbs and shrubs.

So seldom do men intrude on these lonely islands that myriads of sea-fowl choose them for a refuge. Flocks of birds stream so densely off them as to resemble sometimes a volume of smoke rising from a bush-fire. Several kinds of turtle—the green, the logger-head and the hawksbill—resort in early summer to the coral islets to lay their eggs in the sand, while dugong graze on the seaweed on the flats in sheltered water.

The wide space of warm, smooth, shallow water enclosed by the Great Barrier Reef is rich in economic products. Pearling (q.v.) is the oldest and the largest business of the Barrier fisheries. The variety that yields the pearls of Ceylon is not taken here, being replaced by larger kinds, the black-lip and the golden-lip—the latter the largest pearl-shell in the world. It is the mother-of-pearl shell, rather than the contained pearls, that forms the staple of the industry; it is exported to be manufactured into knife-handles, buttons and similar articles. The headquarters of the trade is Thursday Island, which commands the rich and extensive grounds of Torres Straits. But valuable, though smaller, fields occur for several hundred miles southwards. The pioneers, gathering the shell that lay exposed on the reefs at low-tide, reaped a rich harvest; as these deposits were exhausted, the search was extended into deeper water by expert native swimmers and divers; then, with the aid of pumps and diving helmets, shell was gathered from still greater depths. So many deaths resulted from work at the limit of human endurance that the law prohibited diving on the deepest beds. From time to time the beds have been stripped to the margin of profitable collecting, but have recovered after a few years' rest.

Bêche-de-mer fishing is another lucrative industry; it produces a harvest worth from 14 to 40 thousand pounds annually, and employs a corresponding number of men and boats. The bêche-de-mer (otherwise called the trepang, sea-cucumber or sea-slug) is a soft, cylindrical animal, sometimes as thick as a man's wrist, which crawls about on coral reefs. An unpleasant habit of voiding the viscera when handled has given it the additional name of 'cotton-fish.' A great number of different kinds are gathered for the market, and there are other species of no commercial value. The 'fish,' as they are called, are picked up at low-tide by men who dive for them in shallow water; they are prepared for export by being boiled alive, gutted and dried—after which the product resembles a crumpled lump of leather. The Chinese, who make it into excellent soup, are the sole consumers.

A smaller industry of recent growth is that of Trochus gathering. Trochus (often spelt 'trocas') is a snail which inhabits a sea-shell like a huge periwinkle, of nacreous substance and pyramidal shape, four inches in diameter, and coloured with broad red and white stripes. Preparation consists merely of gathering the shell on the reefs and ridding it of the snail. The trade is chiefly in the hands of the Japanese; they export from five to ten thousand pounds' worth annually to Japan, where factories are equipped with elaborate machinery for cutting the shell into 'pearl' buttons.

Both green and 'tortoise-shell' turtle are plentiful, but have not as yet been commercially exploited. Dugong (q.v.) are caught for food by the aborigines. No sponge fishery has been established, but 'hard' or second grade, though marketable, sponges are known to occur, and further search may probably discover a superior 'soft' article.

There has been much theorizing about the formation of the Great Barrier Reef. Since raised reefs are unknown in this area, it is plain that elevation has not occurred. Agassiz argued that neither elevation nor depression had happened, and that the Barrier had grown under stationary conditions; but the evidence that he advanced has been denied by subsequent observers. It is generally agreed that the reef has been built up during a period of slow and continuous subsidence. A crumpling inwards of the land has produced both large submergence and a slight emergence. In harmony with this theory are the steep seaward foundation of the reef: the sunken coast-range, whose peaks now form islands in the channel: the intricate dissection of the mainland into bays and capes, the drowned river-mouths of the Queensland coast, and the break-down of an isthmus that once spanned Torres Straits. As regards the evolution of the features in detail, it has been shown that the growth of an individual reef proceeds in a regular cycle. If the axis of the reef, when it reaches the surface, lies along the direction of the prevailing wind, its shape endures; if it lies across the wind, the ends are produced backwards, forming first a crescent, later a horseshoe, and lastly an oval, thus enclosing a lagoon. Then the lagoon walls broaden; the lagoon itself is filled up with sediment; a sandbank spreads on the summit and

is covered with vegetation; and the atoll, grown to a cay, has arrived at maturity. C.H.

Barrington, GEORGE (1755-1804), born at Maynooth in Ireland on 14 May 1755, was the son of Henry Waldron, and the name by which he is now always known was merely assumed at the age of 16 for theatrical purposes. He was evidently a bright boy, for a local physician undertook his early education, and a dignitary of the Irish Church sent him to school in Dublin and expected him to enter the university. In 1771, however, he ran away from school and as 'Barrington' joined a strolling company of players; the manager taught him the gentle art of picking pockets, and very soon he crossed the Channel to London and pursued his trade there in the disguise of a clergyman. He first attracted public notice when in April 1775 he was charged at Bow-street with having robbed Prince Alexis Orloff of a gold snuffbox worth £40,000; but, as Orloff recovered the box from him and did not trouble to appear in court, he could not be convicted. Later on, being caught picking a woman's pocket at the theatre, he was sentenced to three years' hard labour on the hulks at Woolwich; good conduct procured his release within 12 months, but he was caught again and given five years; the eloquence of his speech from the dock induced a well-meaning person to procure his release again, on condition he left the country; within a few weeks he was caught once more and given a year in Newgate, and stood in the dock again in February 1784 (acquitted), April 1785 (acquitted), January 1787 (broke gaol, was attainted and outlawed); became a 'racecourse pest' at Glasgow, Carlisle, Derby, and Newcastle; was in the dock again in December 1789 (acquitted); and on 15 September 1790 was tried at the Old Bailey for picking pockets on a racecourse, and on this occasion sentenced to seven years' transportation. By this time his numerous trials and remarkable acquittals had made him a notoriety; *The Times* in 1794 used him in a satire on Jacobinism as 'Citizen Barrington, Representative from Botany Bay,' and any Fleet-street hack with a melodramatic tale to sell could double his price by attributing it to George Barrington.

King on his way to Norfolk Island saw Barrington in the convict-transport *Active* at the Cape, and reported that he was 'now a religious convert; he performs service and gives a sermon twice on Sundays.' On arrival in Sydney he continued this conduct; Phillip used him as a watchman at the Toongabbie barracks, found him diligent, sober, impartial, and 'eminently serviceable'—to quote Collins—and on 3 November 1792 emancipated him within the colony (he was one of the first three so treated) and granted him 30 acres near Parramatta. Hunter praised him highly and on 17 September 1796 made him chief constable and superintendent of convicts at Parramatta; when he resigned this post in November 1800, he was allowed half-pay as a reward for good service. In 1801 he was said to be a mere living skeleton, emaciated and almost without intelligence, and when towards the end of 1804 (the exact date is disputed) he died, he was officially described as a lunatic.

Round this remarkable person legends of all kinds have accumulated. The facts stated above are authentic from 1775 onwards; the story of his early life is taken from the one book a share in which may with some probability be assigned to him—*A Voyage to New South Wales*, published in London in 1795, with a dedication written (allegedly) at Parramatta in 1793. This passed through many editions, and was translated into French; the greater part of it was probably written up in London from the works of Phillip, Collins and Tench. The other works bearing his name—which are listed as his even by the *Dictionary of National Biography*—are indubitably not his. The famous prologue which he was supposed to have written for the first theatrical performance in Australia is discussed below. W.J.

Barringtonia, a genus of the family Myrtaceae, chiefly tropical, consisting of trees whose habitat is usually a river-bank or seashore. The two species indigenous to Australia are also found throughout Malaysia, and one is common in India. The calyx-tube is ovoid; petals 4-5, adhering at the base to the staminal cup; stamens numerous in several series, joined at the base into a ring or cup; fruit pyramidal, ovoid, or oblong, hard and fibrous; leaves alternate. The fruit is eminently adapted for dispersal by ocean currents, as its inner coat is a layer of fibrous tissue, the interstices forming air-spaces which make for buoyancy. The outer coat is varnished and waterproof. *B. speciosa* is a large tree with big showy flowers. In Fiji the outer portion of its large 4-angled poisonous fruits is used to catch fish by stupefying them. Its timber is yellow, tough and firm, and is useful in cabinet work.

'Barrington' Prologue, THE. In almost all works published during the last 120 years that deal, however incidentally, with the Australian drama, reference has been made to a famous Prologue supposed to have been either written by George Barrington for, or spoken by him at, the opening of the first Australian theatre in 1796. About twenty years ago, however, Alfred Lee, a well-known Sydney bibliophile, discovered the Prologue in a book (described below) which was previously unknown. This book passed with the rest of Lee's collections into the possession of David S. Mitchell (q.v.), and is now in the Mitchell Library at Sydney. Bertram Stevens announced the true source of the Prologue in the *Native Companion* of 30 March 1907.

In 1802 F. and C. Rivington of St. Paul's Churchyard, London, issued a small volume of *Original Poems, and Translations . . . . chiefly by Susanna Watts.* Susanna belonged to the old Leicestershire family of Watts, and was a near relative of Alaric Watts, poet, critic, and founder of the *Standard* newspaper; and her book was advertised as 'sold by all the Booksellers in Leicester.' On p. 84 of this volume occurs the first known draft of a poem described there as follows:

> The Newspapers having announced, that a Theatre was to be opened at Sydney Town, Botany Bay, and Plays to be performed by the Convicts, this Prologue is supposed to have been spoken by the celebrated Mr. B-rr-ngt-n, on that occasion. 1801. By a Gentleman.

To those acquainted with eighteenth century humour the phraseology of this introduction is evidence enough that the poem is avowedly a *jeu d'esprit*, the offspring of some witty gentleman in Susanna's circle: and a pencilled note in the Mitchell Library copy gives the author's name as 'Hy. Carter Esq.'—several other poems in the book being similarly noted as his. The title-page of the book is also backed with a note to the effect that none of its contents had

been ever published before. If further proof is needed that the prologue appeared then for the first time, the date attached to it may be considered decisive. A newspaper announcement of the opening of a Sydney theatre, if made in 1801, could refer only to the second theatre established in 1800 (see DRAMA); and it has never been suggested that the 'Barrington' prologue was connected with this theatre. Furthermore, among the other verses attributed in the Mitchell Library copy to Henry Carter are four more prologues for plays, and two other poems in heroic metre which repeat or adapt phrases from the 'Barrington' prologue. Thus a poem entitled 'The Flight to Paris'—written in January 1802, obviously in anticipation of the rush of British tourists to Paris that occurred as soon as the Peace of Amiens was made—ends with the wish:—

May future Tourists . . . .
Stem Dissipation's wide o'erbearing flood,
And turn their travels to their *Country's Good!*

The Carter authorship may therefore be considered established. Henry Carter, it may be added, died on 30 August 1806, and his obituary notice in the *Gentleman's Magazine* describes him as 'a gentleman of considerable literary attainments and great benevolence.'

Good though it was, the jest would have sunk into undeserved obscurity had not an enterprising publisher in 1802 conceived the idea of attributing to 'the celebrated Mr. Barrington' a *History of New South Wales* the greater part of which is stolen from Collins. While he was stealing, he stole also the Carter prologue, improved several of the couplets, omitted the Shylock couplet (which could not possibly have been spoken in the alleged circumstances), and on pp. 152-3 of the *History* inserted the new version as a prologue spoken at the 1796 opening. It is not there definitely asserted to have been spoken, or even composed, by Barrington; but its occurrence in a book supposed to have been written by him was basis enough for the further attribution to him of both its authorship and its first delivery. It may be noted (*a*) that in the 1801 editions of the *Voyage to New South Wales* (see BARRINGTON, GEORGE), which contain an account of the 1796 opening almost identical with that of the *History*, there is no mention of a prologue; (*b*) that the 1802 *History* version of the Prologue was in the second (1810) edition still further emended, and brought into the form in which it has ever since been reproduced. Below are printed two versions—Carter's original poem, and the 1810 revision.

From *ORIGINAL POEMS*, 1802.

From distant climes, o'er wide spread seas we come,
(Though not with much eclât, or beat of drum)
True patriots all; for be it understood,
We left our country for our country's good;
No private views disgrac'd our generous zeal;
What urg'd our travels, was our country's weal;
And none will doubt, but that our emigration
Has proved most useful to the British nation.
But you enquire, in us whence springs this rage,
"To strut and fret our hour upon the stage?"
Could aught lift, within our former practice, teach,
Talents like ours, dramatic fame to reach?
List, list, Oh list, before this Court I plead,
Our claim well founded to Theatric meed.
He, who to midnight ladders is no stranger,
You'll grant will make an admirable *Ranger;*
To seek *Macheath* we have not far to roam,
And sure in *Filch* I shall be quite at home;
Unrival'd there, none will dispute my claim
To high pre-eminence, and unequal'd fame.
As oft on *Gadshill* we have ta'en our stand,
"When 'twas so dark, you could not see your hand,"
Some true-bred *Falstaff* we may hope to start,
Who, when well-bolster'd, well will play his part.
The scene to vary, we shall try in time,
To treat you, now and then, with Pantomime;
Here light and easy Columbines are found,
And well-try'd Harlequins with us abound;
From durance vile our precious selves to keep,
We oft had recourse to the flying leap;
To a black face have sometimes ow'd escape,
And Hounslow-heath has prov'd the worth of crape.
But how, you ask, can we e'er hope to soar
Above these scenes, and rise to tragic lore?
Oh! we have forc'd, too oft, th' unwilling tear,
And petrify'd the heart with real fear;
Macbeth a harvest of applause will reap,
For some of us, I fear, "have murder'd sleep."
His *Lady*, too, with grace, will dream and talk;
Our females have been us'd at night to walk;
While *Shylock*, thirsting to extinguish life,
With ready hand will whet the murderer's knife:
Sometimes, indeed, so various is our art,
An actor may improve and mend his part;
"Give me a horse," bawls *Richard*, like a drone;
We'll find a man would help himself to one.
Grant us your favour, put us to the test;
To gain your smiles we'll do our very best,
And, without dread of future Turnkey *Lockits*,
Thus, in an honest way, still *pick* your *pockets*.

From *HISTORY OF NEW SOUTH WALES*, 1810 edition. (Principal alterations in lines 9-14, 20, 26, 30, 35, 39; lines 41-2 omitted.)

From distant climes, o'er wide-spread seas, we come,
Though not with much eclat, or beat of drum:
True patriots all; for, be it understood,
We left our country, for our country's good;
No private views disgrac'd our generous zeal,
What urg'd our travels was, our country's weal;
And none will doubt, but that our emigration
Has prov'd most useful to the British Nation.
But, you inquire, what could our breasts inflame
With this new passion for Theatric fame;
What, in the practice of our former days,
Could shape our talents to exhibit plays?
Your patience, Sirs, some observations made,
You'll grant us equal to the Scenic trade.
He, who to midnight ladders is no stranger,
You'll own will make an admirable Ranger.
To seek Mackheath we have not far to roam,
And sure in Filch, I shall be quite at home.
Unrivall'd there, none will dispute my claim
To high pre-eminence, and exalted fame.
As oft on Gadshill we have ta'en our stand,
When "'twas so dark you could not see your hand,"
Some true bred Falstaff we may hope to start,
Who, when well bolster'd, well will play his part.
The scene to vary, we shall try, in time,
To treat you with a little pantomime.
Here light and easy Columbines are found,
And well-try'd Harlequins with us abound;
From durance vile our precious selves to keep,
We often had recourse to th' flying leap;
To a black face have sometimes ow'd escape,
And Hounslow Heath has prov'd the worth of crape.
But how, you ask, can we e'er hope to soar
Above these scenes, and rise to Tragic lore?
Too oft, alas, we've forc'd th' unwilling tear,
And petrify'd the heart with real fear.
Macbeth a harvest of applause will reap,
For some of us, I fear, have "murder'd sleep;"
His lady, too, with grace will sleep and talk,
Our females have been us'd at night to walk.
Sometimes, indeed, so various is our art,
An actor may improve and mend his part:
"Give me a horse!" bawls Richard, like a drone,
We'll find a man would help himself to one.
Grant us your favour, put us to the test,
To gain your smiles we'll do our very best;
And, without dread of future turnkey Lockits,
Thus, in an honest way, still pick your pockets.

Barron, SIR HARRY (1847-1921), son of Charles Robert Barron of Denmark Hill, London, was born on 11 August 1847, educated at Tunbridge Wells and Woolwich, and in 1867 entered the royal artillery (lieutenant, 1867; captain,

1879; major, 1884; lieutenant-colonel, 1894; colonel, 1898; major-general, 1904). From 1897 to 1900 he was chief instructor of the school of gunnery at Shoeburyness, and was then given command of the royal artillery in the Thames district, taking a similar position at Malta in 1904. When he retired from active service in 1909, he was made governor of Tasmania, and transferred in 1913 to Western Australia. In 1917 he retired from this position also, and spent the rest of his life quietly at Weybridge in Surrey, receiving in 1920 the position of colonel commandant in the royal artillery. He died on 27 March 1921. (C.V.O., 1907; K.C.M.G., 1909).

Barry, Alfred (1826-1910), born in London on 15 January 1826, and educated at King's College, London, and Trinity College, Cambridge (B.A., 1848; M.A., 1851; B.D., 1860; D.D., 1866; D.C.L., 1870), distinguished himself both in mathematics (4th wrangler and 2nd Smith's prizeman, 1848) and classics (7th in 1st class of classical tripos) and was made a fellow of Trinity. He took orders in 1850 (priest, 1853), but until 1871 devoted himself to educational work, being vice-principal at Glenalmond in 1849-54, headmaster of the Leeds grammar school in 1854-62, principal of Cheltenham College in 1862-68, and principal of King's College, London, in 1868-71. In 1871 Gladstone made him a residentiary canon of Worcester; in 1875 he became honorary chaplain to Queen Victoria, and in 1879 chaplain in ordinary; in 1881 he was, again by Gladstone, made a residentiary canon of Westminster Abbey. In 1876 he refused the bishopric of Calcutta, but in 1883 accepted that of Sydney, and was consecrated in Westminster Abbey on 1 January 1884.

He was, however, never at home in Australia. His active and highly intellectual mind faced boldly, but with a good deal of distaste, the crude conditions and comparatively petty problems of colonial administration, and his clergy found the value of his guidance, great though it undoubtedly was, somewhat diminished by a too apparent lack of sympathy. In a five years' term he managed to include several visits to England, and in 1889 resigned the see and returned to England for good. His absence had injured his chances of further preferment, and for the rest of his life he was never more than an official or unofficial assistant to English bishops. Thus he was assistant to the bishop of Rochester in 1889-91, locum-tenens for the bishop of Exeter in 1891, and (as rector of St. James, Piccadilly) assistant to the bishop of London in 1895-1900. In 1891 he was made a canon of St. George's chapel at Windsor, and from 1900 to the day of his death—1 April 1910—confined himself to the duties of that position. He was a powerful orator and a sound administrator, but his literary work—except that which embodied the substance of his Boyle lectures (1876-8) and Hulsean lectures (1894)—was not of outstanding merit.

Barry, Sir Redmond (1813-1880), born at Ballyclough near Cork in Ireland was the third son of Major-general Henry Green Barry. Educated at Trinity College, Dublin (B.A., 1833; LL.D., 1876), he was called to the bar in 1838 and the next year migrated to Sydney, going on almost immediately to the young town of Melbourne. There in 1841, when branches of the New South Wales supreme court and court of requests were established, he was appointed commissioner of the latter court. At first he lived in a small cottage fronting the lane just west of the Bourke-street synagogue; in or after 1843 he moved a little farther west to a larger (5-roomed) cottage close to Goldsborough's woolstore; and in both houses he seems to have set aside one room for a public reading-room, supplied with standard works and many current English magazines, to which he invited anyone who had not a home of his own to spend his evenings in. The action symbolized his whole life, which was devoted, to the utmost of his power, to promoting the educational and artistic growth of the community he lived in. When in 1851 Victoria became a separate colony, Barry was made solicitor-general and given a seat in the council; in 1852 he was promoted to the supreme court bench, and remained there till his death in 1880, acting as chief justice on several occasions and (for a few days) as administrator of the government in 1876-7.

His greatest services to Victoria, however, lay in another direction. 'Though not a man of deep learning himself,' says Gyles Turner, 'he had been above all others the means of bringing both learning and learned men to the colony . . . . The University, the Public Library, and the National Gallery were his foster-children, and for their advancement he worked with unceasing activity.' (*History of Victoria*, ii. 222.) These were 'the invaluable services' commemorated on the pedestal of his statue in front of the Melbourne public library. Childers and Latrobe inaugurated the movement for establishing a university, but Barry's was the persistent and considered zeal that nursed it to maturity; he was its first chancellor, and retained the position till his death. The library owes him no less, and he was rightly made the first president of its trustees; his work in this respect was so valued that during a visit to England in 1877 he was made vice-president of a great conference of librarians, at which he read important papers. He was a commissioner for Victoria at both the London international exhibition of 1862 and the Philadelphia centennial exhibition of 1876. He died in Melbourne on 22 November 1880. (Kt. Bach., 1860; K.C.M.G., 1877.)

Barry, Shiel. See Donohoe, Andrew.

Barton, Sir Edmund (1849-1920), born at the Glebe, Sydney, on 18 January 1849 and educated at the Sydney Grammar School and the university of Sydney (B.A., 1868; M.A., 1870), was called to the New South Wales bar in 1871 and became a Q.C. in 1889. Preferring politics to law, he contested the university seat unsuccessfully in 1877 and successfully in 1879; but in that year university representation was abolished, and Barton became successively member for Wellington (1880-1), East Sydney (1882-7 and 1891-4), and the Hastings and Macleay (1898-9), interpolating two terms (1887-91 and 1897-8) as a member of the legislative council. From 1883 to 1887 he was speaker of the legislative assembly, and might have been premier when he left the chair, but for a certain constitutional laziness that more than once hampered his career. Partly because he believed in protectionist tariffs, partly from distrust of Henry Parkes, he attached himself to George Dibbs, then leader of the opposition, and when that leader came into office was his attorney-general in the 1889 ministry, as well as (for a time) in that of 1891-4. But by that time Barton's whole outlook upon local politics had altered. From the commencement of the final movement towards federation he abandoned all minor interests to devote himself

to that cause. In the 1891 convention he was one of the representatives from New South Wales, and one of the four members chosen by the convention to draft the constitution bill; later in the year he stood (and was elected) for East Sydney as a federationist, and joined the Dibbs ministry explicitly as the leader of the federal movement in New South Wales—a position which he took up at the direct request of Sir Henry Parkes. The dual position, however, proved impossible; though in 1892 he carried through the assembly a pro-federal resolution, he found (to use his own words) that certain colleagues were 'always strewing tacks in my path;' and in December 1893 he resigned office on a personal question in order to regain full freedom for carrying on outside the cabinet the campaign for the 1891 bill. Unfortunately that campaign was already moribund. New South Wales was for the moment interested solely in the fight between freetraders and protectionists, which raged with all the greater fury because George Reid, the new freetrade leader, was advocating a drastic system of land taxation. Nevertheless Barton maintained a persistent attack on the popular mind by a series of addresses—nearly 300 in four years—designed to explain the principles of the 1891 bill. He was never a really popular speaker, and the addresses fell flat as far as the public was concerned, the agitation for federation during those years being revived by different means (see FEDERATION); what he did achieve was to attract and inspire a number of young men, most of them from the various universities, who when the great effort of 1897-9 was being made became missionaries of the idea throughout Australia, and looked up to him all the while as their hero.

When the Quick proposals of 1894, as modified by the Hobart enabling bill of 1895, at last found fulfilment in the federal convention elections of 4 March 1897, Barton headed the poll for New South Wales with nearly 75 per cent of the total votes polled, and when the convention met was without difficulty made 'leader of the Convention' and chairman of a constitutional committee. This body at once appointed him chairman of the sub-committee that drafted the new bill, and the Commonwealth act, though much trimmed and partly re-shaped in the various meetings of the convention and by the British authorities, owes a good deal to his work. When the period of conventions was over and the referendum campaign began, Reid's notorious 'Yes-No' attitude made the thorough-going Barton more than ever the leader of the eager federalists; the campaign proving at last successful, he was made the New South Wales delegate to London to help the Commonwealth bill through the Imperial parliament, and when the process was complete and the first governor-general reached Australia, it was expected everywhere that he would at once be made prime minister. An obscure intrigue, however, which was directed towards making Sir W. Lyne prime minister first astonished and then angered the public, and ended ignominiously. The men who, as everyone knew, must be included in the first federal cabinet would serve under no one but Barton; he therefore took the prime-ministership along with the department of 'external' affairs (i.e. the relations of Australia with the mother-country and with other nations through her)—and almost at once, under the influence of one of his recurring fits of laziness, dropped out of active politics and allowed his subordinates to go their several ways. His one personal contribution to federal policy was unfortunate; it was the naval agreement of 1902 (for which see NAVAL DEFENCE), which reduced Australia's share in the defence of the Empire to a mere subsidy of the admiralty, and did much to lose seats for many of his supporters in the elections of 1903. Before then, however, Barton had left politics for ever, retiring in September 1903 to the dignified seclusion of the high court bench, where he was quite overshadowed by the brilliant energies of Sir Samuel Griffith and was apparently content to be known as the embodiment of the court's 'concurrent' jurisdiction because he almost invariably concurred in the bigger man's judgments. The history of his later years, except where it was interrupted by severe illness, is a record of honoured but on the whole inactive serenity. He died at Medlow on the Blue Mountains (N.S.W.) on 7 January 1920.

One of the great names of modern Australia, Barton was not actually a great man, though he easily might have been. The cause of federation alone was near enough to his heart to make him work really hard; and, just because he never worked really hard for any other object, he lacked the experience of popular needs and feelings that made far less able politicians far more effective advocates. To the cause of federation he made two invaluable contributions—the legal and constitutional skill which moulded the instrument of government, and the inspiration (born of his high ideals, his unselfish aims, his lovable character) which he afforded to the young missionaries already spoken of. (P.C., 1901; G.C.M.G., 1902.)

Barytes occurs almost all over the Commonwealth, but has been obtained for commercial purposes chiefly in South Australia, which in the three years 1920-22 produced 8231 tons. In 1920 Tasmania produced 1000 tons (no later production is recorded), and in 1920-1 New South Wales produced 622 tons. Willunga in South Australia is the chief centre of the industry; it has extensive deposits, in veins varying from two to seven feet in thickness, of mineral of good quality but slightly discoloured by iron. Large deposits, still unworked, are known to exist in Victoria and Western Australia.

Basking Shark (*Cetorhinus maximus*), one of the largest of recent sharks, attaining a length of 35 feet. Notwithstanding its great size, it is quite harmless to man, and feeds upon minute floating animals, which are evidently strained from the water by means of peculiar comb-like structures upon the gill-arches. It is said to be sluggish, and derives its vernacular name from a habit of floating almost motionless near the surface of the sea; at such a time it perhaps collects the drift-life which forms its food. It ranges over all temperate seas, and several large specimens have been taken in southern Australian waters. The teeth are very small, weak, and numerous, about 200 being in each row. Another characteristic feature lies in the great size of the gill-openings. The basking shark is sometimes sought for the oil contained in its liver, of which a large quantity is obtained from each individual; its capture is not unattended with danger, since a blow from the tail of a large specimen is sufficient to stave in the sides of a whaleboat.

A.R.McC.

Bass, GEORGE (1763-1808?), son of a Lincolnshire farmer, was born at Aswarby in that county; but on his father's death the family moved to the neighbouring town of Boston, and

the boy was apprenticed to a local surgeon. Obtaining his diploma in London, he was established by his mother as a village apothecary in his native county; but the passion for a seafaring life which had sprung up in him as a boy could not be suppressed—he abandoned his shop, and obtained a commission in the royal navy as surgeon to H.M.S. *Reliance*, which on 15 February 1795 left Plymouth for Australia. She carried Governor Hunter; she carried also—as a midshipman, not as a passenger—Matthew Flinders.

Between Flinders and Bass, both Lincolnshire men, there sprang up during the voyage a firm and long-lasting friendship. Twenty years later, when they had been long separated, Flinders narrates with a sort of fiery pleasure his first acquaintance with 'a man whose ardour for discovery was not to be repressed by any obstacles, nor deterred by danger,' and accompanies almost every reference to his companion in many dangerous explorations with epithets of affection and eulogy. No sooner were the two young men in Port Jackson, and at liberty from the ship's routine, than they began a career of adventure that has left its mark on Australian history. The detailed story of their explorations will be found under EXPLORATION BY SEA; but it may be said here that they included (*a*) a journey up George's River in a boat eight feet long with a 5-ft. beam, (*b*) a journey down the coast almost to Lake Illawarra, in a slightly bigger boat, (*c*) after an interval during which the *Reliance* was sent to South Africa to fetch back live stock, Bass's famous voyage in the whaleboat to Western Port, (*d*) Flinders's trip in the *Francis* to the Furneaux Islands, (*e*) the Bass-Flinders circumnavigation of Tasmania in the *Norfolk*. Of these the whaleboat voyage was at the time particularly and deservedly renowned; Péron in 1802 writes that the boat itself was preserved on the foreshore of Port Jackson 'with a kind of religious respect,' and souvenirs were made from its timbers.

Nor was Bass's adventurous spirit content with exploration by sea. In June 1796, after the Illawarra voyage, he attempted the piercing of the Blue Mountains barrier, but failed because he used the European method of working up the valleys, so that as soon as he climbed to the top of a ridge—by following which he could have anticipated Blaxland's achievement—he carefully and futilely let himself down again into the impassable gorge below (see EXPLORATION BY LAND). And in 1797, just before the whaleboat voyage, he discovered veins of coal at Coalcliff in northern Illawarra, and made a walking tour from Sydney to the Cowpastures and thence due east to the sea. It was possibly for the discovery of coal that Hunter gave him 100 acres at Bankstown; for the grant was made before the whaleboat voyage was completed.

In May or June 1799 Bass returned to England—why or how we do not know—and is next heard of as marrying, in October 1800, the sister of his old commander Waterhouse. Early in the following year a small (142-ton) brig, the *Venus*, sailed from England to take up trading in the South Seas, with Bass as managing owner and supercargo, acting on behalf of a syndicate of friends and relatives. She reached Sydney on 28 August, and was almost immediately employed in fetching salt pork from Tahiti and salt from Hawaii. Even in commercial work, however, Bass remained adventurous; after two Tahiti voyages pork could not content him—he contracted with Governor King to buy a government brig that had been wrecked on Tahiti, proposed to him a 7-year lease of the southern coast-line of New Zealand in order to establish there fisheries on a large scale, and enlarged his plans for a third trip to Tahiti by adding one to Peru in search of guanacoes. For this purpose King gave him a certificate showing that he was engaged on public business 'without any view to private commerce or any other view whatsoever.' He sailed from Sydney on 5 February 1803: and that is all we know.

It is worth noting that he still ranked as a naval officer, and in 1803 made an official report, as 'navy surgeon,' on the health of Lieutenant-governor Paterson. It must also be remembered that Péron, in 1802, was very alarmist about designs of the British government on Spanish Peru, and alleged that both by piratical attacks on Spanish vessels and by supplying arms and ammunition to the rebel Chileans Britain hoped to expel Spain from South America. In these circumstances it is not difficult to conjecture that the arrival of a British merchant vessel, commanded by a naval officer, in a Peruvian port might give rise to suspicions which even King's certificate could not altogether dispel; and we need not surmise that Bass was in reality trying to run a trade in contraband (the arguments for this surmise will be found in Scott's *Matthew Flinders*, pp. 149-54; those against it in the *Historical Records of Australia*, I., iv. 669-70). Early in 1805 the master of a British vessel, the *Harrington*, which had been privateering off the South American coast, reported that the *Venus* had been captured by the Spaniards and Bass sent as a prisoner to the mines inland; this is quite in accord with the rough and ready procedure of colonial governments in those days, and may be accepted as true. King, it should be noted, at the end of 1804 was still 'in constant expectation of hearing' from Bass, but after the arrival of the *Harrington* does not again allude to him. A rumour quoted (without acceptance) in the *Historical Records* which makes him still alive in South America in 1817 is too vague and unsupported to need closer consideration. Indeed, there are reasons for believing that he died in or before 1808.

Of Bass's appearance and character we know a good deal. He was six feet in height, handsome, dark, with very keen eyes (several friends use the word 'penetrating' in connection with his look). Flinders, who knew him most intimately, kept up a correspondence with him after their separation, was gravely disappointed when they missed each other in 1802-3, and submitted his own work to his friend's criticism with obvious respect as well as affection. Hunter had a high opinion of him. And his own doings and writings show him alert, resourceful, courageous, impatient of inactivity, and at the same time modest and unassuming beyond the normal—a man, that is, who wanted to get things done and rightly done, and was not much troubled about getting the credit for having done them.

Batchelor, EGERTON LEE (1865-1911), born at Adelaide on 4 April 1865 and educated at the North Adelaide public school, in 1877 became a pupil-teacher there, but in 1882 entered the locomotive workshops of the South Australian railways as an apprentice, and rose to be foreman. In 1889 he joined the Amalgamated Society of Engineers (in which later on he was four times president of the South Australian branch), and in 1891 left the workshops to enter politics. In 1893 he was elected senior

member for West Adelaide in the assembly, and held the seat until 1901, with C. C. Kingston (q.v.) as his junior colleague for 6½ years. He was also secretary of the South Australian Labour party until 1898, when he was chosen its leader. In December 1899 he joined the coalition ministry of F. W. Holder (q.v.) as minister of education and agriculture, but resigned in 1901 to enter the Commonwealth parliament, in which he was for a time the only Labour member from South Australia. In 1903 he became federal member for Boothby, and retained the seat until his death. In the Watson ministry of 1904 he was minister for home affairs, and minister for external affairs in the Fisher ministries of 1908-9 and 1910-11. In 1911 he accompanied Andrew Fisher to the Imperial Conference of that year, but shortly after his return from England died suddenly of heart failure at Warburton near Melbourne on 8 October. An obituary notice in *The Times* emphasized both the friendships he had made among British statesmen and 'his sound common sense and cool judgment' in the debates of the Conference.

Batfish, tropical fishes (*Platax*) which swim in small schools, and are widely distributed throughout the Indian and Pacific Oceans. They are rounded and sometimes deeper than long, and the body is greatly compressed; the anterior rays of the dorsal and anal fins are so greatly lengthened in the young that they trail backwards as pointed lobes, giving the fish a crescent shape. They alter considerably in appearance with growth, however, and it is often difficult to associate the young with the adults. The upper and lower processes of the vertebral column commonly develop large bony bosses; these, though apparently normal, have been supposed to be the result of disease, and one species has even been named *Platax arthriticus* in the belief that it was affected with arthritis. The Silver Batfish (*Monodactylus argenteus*) is an allied species of similar habits and distribution. It is common on Australian coasts, extending southward to Sydney.

A.R.McC.

Bathurst, Henry (1762-1834), 3rd Earl Bathurst, born on 22 May 1762, and educated at Christ Church, Oxford (where he matriculated in 1779, but in accordance with the custom of the time took no degree), during his youth contracted an intimate friendship with William Pitt the younger, who made him in 1783 a lord of the admiralty, in 1789 a lord of the treasury, and in 1790 a teller of the exchequer; this last office he held till his death. In 1793 he entered parliament as member for Cirencester, but vacated the seat in the following year because, owing to his father's death, he had become a member of the house of lords. When Pitt formed his second ministry in 1804, he offered Bathurst the mastership of the mint; Bathurst refused, not feeling himself entitled to such high office, but Pitt insisted. After Pitt's death he was president of the board of trade under the Duke of Portland and Spencer Perceval (1807-12), as well as master of the mint, and for a few months in 1809 was also foreign secretary. Lord Liverpool, who became premier after the assassination of Perceval, made Bathurst secretary for war and the colonies; this office he held until 1827, and from 1828 to 1830 was lord president of the council under the Duke of Wellington, with whom he had had intimate and satisfactory dealings during the latter part of the Peninsular war. He was, indeed, the best and most intelligent, if not the ablest, of all the war ministers with whom Wellington had to deal. A Tory of the old school by conviction, he yet favoured Catholic emancipation and the abolition of the slave trade, but could not abide parliamentary reform, and after the passing of the reform act of 1831 abandoned politics altogether. He died on 27 July 1834.

Bathurst's interest for Australia centres on his long administration of the colonial office. In the earlier years of it, when he was engaged in helping Wellington to win the war, he trusted a good deal to Henry Goulburn (q.v.); as the post-war ferment decreased and military affairs receded into the background, he began to take a personal interest in New South Wales affairs. In 1816 he supported Macquarie's action against the Bents, and his letters thereanent betray the personality of a strong and sober patriot, concerned rather with the public advantage than with technical points or personal prejudices. In 1817 he discussed at length the exploration of the interior, and insisted on the continuation by P. P. King of Flinders's surveys along the coast. During the same year, however, he took occasion thrice at least to censure Macquarie for undue severity—trusting, apparently, to accusations backed by Samuel Marsden. Macquarie promptly tendered his resignation, and Bathurst's reply of 18 October 1818 is a model statement of what should be the relations between a good governor and a good colonial secretary. Even when in 1819 he sent out J. T. Bigge, he definitely gave Macquarie permission to disregard the commissioner's wishes, though he naturally deprecated such a course. It might have been better if his first intention (expressed in his letter of 23 April 1817 to Lord Sidmouth, then home secretary) of appointing several commissioners had been carried out; for it was clearly Bigge's personality, not Bathurst's desires, that brought about the somewhat troubled close of Macquarie's rule. Bathurst, as his letter to Sidmouth and his farewell letter to Macquarie (10 September 1822) show, was concerned about the new conditions imposed on the colony by an excessive influx of convicts rather than about any supposed misdeeds of Macquarie's.

His correspondence with Brisbane strengthens the impression already formed of his good sense and loyalty to his officials. He adopted Bigge's recommendations in the main, but gave Brisbane—who was on the spot and could bring a fresh judgment to bear—full discretion to postpone any of them and supply the office with further information on the subject. Once again he showed an inclination to take anything Marsden said for gospel, but proved open to conviction. The one fault he would not pardon—as in the brothers Bent, so in Brisbane and Frederick Goulburn—was personal jealousy that impeded the public service; and he objected also to governors who, while shifting to his shoulders the responsibility of important action, did not aid him to the utmost extent with their expert advice. Thus he rebuked Darling in 1826 for forwarding a report from Archdeacon Scott without having taken time himself to examine the recommendations minutely and with acquired experience. In fact, everything we know of him depicts him as a statesman of unfailing good sense, not brilliant in parliament, but all the better suited to administer a great department; conservative, philanthropic, devoted to the public interest, but preserved by an unfailing sense of humour from the ponderous officialism that too often handicaps British statesmen. (K.G., 1817.)

Batman, JOHN (1800-1839), born at Rose Hill (now Parramatta) in 1800 and educated locally—he was a schoolfellow of Hamilton Hume (q.v.)—was the eldest son of William Batman, a settler who reached New South Wales in 1797 and soon became a member of the circle of pious men who gathered round the missionaries from Tahiti (see OAKES, REBECCA). John was brought up to the blacksmith's trade, but in 1821 left New South Wales to settle in Tasmania at Kingston in the Fingal district on the flanks of Ben Lomond. In 1826 he made himself notable by capturing singlehanded the dangerous bushranger Matthew Brady, and in 1828-30 made himself useful to Governor Arthur by his tactful and humane handling of the natives during and after the so-called 'Black War.' Meanwhile he had formed a close acquaintance with J. T. Gellibrand (q.v.), and in 1827 joined him in a proposal to establish a settlement at Western Port, which Darling, then governor of New South Wales, refused to entertain. At that time, it should be remembered, it was still supposed that the fine country through which Hume and Hovell passed towards the end of their famous journey was on the shores of Western Port. In 1831, however, Dr. Bland disclosed to the public what Hovell himself had known since 1826—that the explorers had reached the western shores of Port Phillip; Batman's hopes were therefore transferred to that district, and in 1834 he proposed to some friends the colonization of the yet untouched area without seeking any governor's permission in advance. (It is extremely probable, at the same time, that Arthur knew of the proposals and approved them; but as governor of Tasmania he had no status in the matter, Port Phillip lying within the colony of New South Wales.) According to one of his associates, Batman then declared that he had gathered his information about the area to be settled from Hume personally; but this is doubtful. In any case an association was formed there and then, Batman and Gellibrand being its most active members, and the other 13 including Arthur's nephew Henry; Gellibrand drew up formal deeds of conveyance—for the rights of native owners were to be strictly respected—and on 10 May 1835 Batman left Launceston in the schooner *Rebecca* with three white men and six aboriginals of some New South Wales tribe. Not till the 26th could he clear the Tamar heads, and it was two days more before he could leave the Tasmanian coast, but by midday on the 29th the *Rebecca* was anchored near Indented Head. Two days were spent in exploring south and west of Corio Bay (the area, be it remembered, of which Hume had given such glowing accounts); then the *Rebecca* was brought up to Yarra mouth and anchored off the bar, and Batman made a sweeping march up the Saltwater River, round past Sunbury, and down towards the Plenty. Near this stream he met a tribe of natives, and seized the opportunity to obtain the signatures of their camp-council to the deeds drawn up by Gellibrand; he had met no other adult males since his landing, and was quite ready to assume that they owned the whole territory and could, as 'chiefs,' grant it away. (This grant is more fully discussed under VICTORIA.) The documents once signed, he hurried back to Tasmania—after a brief inspection of the lower Yarra, for which see MELBOURNE, and the establishment of an occupying party on Indented Head—reached Launceston on 11 June, and by the 25th had with Gellibrand's help prepared a memorial asking for confirmation of the purchase and promising a definite scheme of colonization; this was signed by all the members of the association. Arthur could not hold out much hope, but sent the memorial on to London with a strong recommendation that something should be done for Batman.

Meanwhile another party had taken a hand in the game. The story of John Pascoe Fawkner's settlement on the Yarra will be found under FAWKNER and MELBOURNE. Here it need only be mentioned that his party deliberately settled down along the Yarra at the head of tide-water (on land previously visited by Batman and claimed by him under the purchase-deeds), maintained their position in spite of a formal notification given them by J. H. Wedge, one of the association, and were in the end allowed by the British government to purchase at a reduced rate the sites they had actually occupied. The Batman camp at Indented Head was at once moved to the Yarra, and by the middle of September both parties were ensconcing themselves on 'Batman's Hill' (on which the Melbourne law-courts now stand). Fawkner himself arrived on the Yarra on 10 October, and Batman on the 26th; the latter proceeded to mark out his personal share of the great purchase—a block extending from the Saltwater to the Plenty and about 15 miles northwards from the Yarra settlement. But already his plans had been annulled. Governor Bourke on 26 August proclaimed the purchase void and all white residents of Port Phillip intruders and trespassers; he had no intention, probably, of taking any active steps against them, but his proclamation put them outside the law, prevented them from establishing any sort of title to any land, and left the situation entirely in his own hands whenever he obtained from England authority to do anything. This he at once asked for; Batman's proceedings, he told the authorities in London, could not establish a lasting and law-abiding colony, but it might be advisable to make an official settlement at Port Phillip under the usual conditions, and so bring the new arrivals under proper legal control. In April 1836 approval was given to these proposals, and in September William Lonsdale reached Port Phillip and took charge as superintendent of the settlement. Batman had earlier in the year (about April) transferred his permanent home from Tasmania to Port Phillip and built a house on land, just outside the south-western corner of the settlement, which he claimed under his grant from the association. Here he lived for three years, although in June and November 1837 he purchased eight lots inside Melbourne at the official land-sales; but the government would give him no title to the outside area, repeated appeals failed to procure for him any substantial concession, and, even when the British colonial secretary expressed the opinion that he should be allowed the value of his improvements, the New South Wales government would only allow him to remove to another site the materials of the house and other movable property. Before this concession was obtained Batman died on 6 May 1839, and in the end the administrator of the settlement bought the cottage for £200. Australian pioneers have often suffered misfortunes, but few have been treated so harshly by their fellow colonists in official positions as was John Batman.

Batrachia. See AMPHIBIA.

Bats, an order (*Chiroptera*) of mammals comprising two sub-orders—the Megachiroptera

or fruit-eating bats ('flying foxes') and the Microchiroptera or ordinary bats, the great majority of which feed exclusively on insects. Both sub-orders are well represented in the Australian region. Of flying foxes there are seven Australian species; by far the most widely distributed is the Grey-headed Flying Fox (*Pteropus poliocephalus*), which frequents New South Wales, southern Queensland and parts of Victoria. It is distinguished from other species of *Pteropus* by the bright reddish-yellow colour of the fur on the neck, shoulders and fore-part of the breast, that on the back being greyish-black and on the head grey with a yellowish tinge. The Dusky Flying Fox (*P. brunneus*), which is yellowish-brown all over, has hitherto been found only on the Percy Islands, off the Queensland coast. Gould's Flying Fox (*P. gouldi*) is black all over, except for a brown patch on the back of the head and neck (the neck-patch in adult males is sometimes bright yellow); it is widely distributed in northern Queensland and on the islands off that coast. The Spectacled Flying Fox (*P. conspicillatus*), with a ring of pale brownish-yellow round each eye, also occurs in northern Queensland, but extends across Torres Straits to Yule Island in Papua. The Collared Flying Fox (*P. scapulatus*), which has a pale band round the neck, is another northern Queensland species. *Nyctimene papuanus* and *N. robinsoni*, which occur in north-eastern Queensland, are smaller than the ordinary fruit-eating bats, and have projecting tubular nostrils.

The smallest of all the fruit-eating forms, said to be exceptionally destructive, is the Little Flying Fox (*Syconycteris australis*) which has a very wide range—from western and northern Australia through the Malay Archipelago to the Philippines, as well as in New Ireland and the Solomons.

Of Microchiroptera, the ordinary insectivorous bats, Australia possesses a large number of species, belonging to many genera and several families. The great majority of Australian bats are not known to occur outside the region, and some are limited to particular parts of Australia; but a few have a wider range—two are found in Europe, and one in Africa. Of the two species that occur in New Zealand one is found also in south-eastern Australia. The most abundantly represented family is the Vespertilionidae; it consists of bats devoid of the elaborate nostril appendages present in the other families. The genus *Nyctophilus* is peculiar to the Australian region, taking the place occupied in northern lands by *Plecotus*—the genus to which the British long-eared bat belongs. The nine species of *Nyctophilus* have a wide range, extending over continental Australia, Tasmania, and the islands to Fiji on the east. The Little Bat (*Eptesicus pumilus*), which is only 1½ inches long and has black fur both above and below, is also widely distributed in Australia and Tasmania, but does not extend beyond the boundaries of the Commonwealth. The Yellow-headed Bat (*Pipistrellus abramus*), which is a little larger, extends from northern Australia to the Malay Archipelago, southern Japan, and Ceylon, and in summer is found in central Europe. A larger species of the same genus—Krefft's Bat (*P. tasmaniensis*)—inhabits New South Wales and Tasmania. The Chocolate Bat (*Chalinolobus morio*), widely distributed in extra-tropical Australia, is the species referred to above as extending to New Zealand; it is figured on plate xi. Other common species are Gould's Bat (*C. gouldi*) of eastern and south-eastern Australia and Tasmania, the Pied Bat (*C. nigrogriseus*) of northern and eastern Australia, Rüppell's Bat (*Scoteinus rueppelli*) of New South Wales, and the Great-footed Bat (*Leuconoë adversa*) which extends from Siam through Java, Borneo, and Celebes to northern Australia. The family Rhinolophidae, in which the nose is provided with leaf-like appendages, is represented by four Australian species. In the Greater Horseshoe Bat (*Rhinolophus megaphyllus*), of Queensland and the northern rivers of New South Wales, a part of these appendages assumes the form of a horseshoe. The Great Blood-sucking Bat (*Macroderma gigas*), which has only been found in the Wilson's River district of central Queensland, belongs to a genus of wide distribution in Asia and Africa, the members of which feed not on insects alone, but on smaller bats, other small mammals, and other vertebrates. The head and body have a length of over five inches.

Bat's-wing Coral. See ERYTHRINA.

Baucra, a genus of the family Saxifragaceae, endemic in Australia, consisting of three species of shrubs. The calyx is divided to the base into 6-10 spreading segments, often toothed; stamens inserted round a narrow disk; fruit a capsule opening in two valves; leaves opposite, each divided into 3 leaflets attached to the branch horizontally by their bases, giving the impression of a whorl of 6 leaves. *B. rubioides* (Native Dog-rose) is a scrambling shrub, usually found near a watercourse; in the blooming season it is covered with pink flowers. The flowers of *B. capitata* are terminal. *B. sessiliflora* is confined to the Victorian Grampians.

Bauhinia, a genus of the family Leguminosae, consisting of trees or woody climbers, chiefly tropical. The leaves are divided into two distinct leaflets, or united into an entire or 2-lobed leaf. *B. Carroni* (Queensland Ebony), the 'pegunny' of the Cloncurry River natives, is a small tree with a light-brown, heavy wood suitable for veneers. *B. Hookeri*, a large tree, also known as Mountain Ebony, has a similar timber.

Becke, GEORGE LEWIS (1855-1913), better known as 'Louis Becke,' was born at Port Macquarie in New South Wales on 18 June 1855 and educated locally and at Fort-street school in Sydney. At the age of 14 he was sent by an uncle to California to learn trading in the employ of a San Francisco firm; the voyage, which was made over devious routes, took 130 days, and the boy was enchanted by glimpses of island life. Soon after his arrival in America he left San Francisco to work in a coastal trader, and at 16 shipped aboard a vessel engaged in catching sharks off Christmas and Palmyra islands. For a time he was em-

ployed as supercargo in an island trader: then (in 1874) he revisited Australia, spent two years on the newly discovered Palmer goldfield in Queensland, and was employed for a short time by the Australian Joint Stock Bank's Townsville branch. But the Pacific had too strong a hold on him: by 1879 he was back in Samoa, and during a visit to the Marshalls met the notorious 'Bully' Hayes, with whom he worked for some years as supercargo. During the eighties he traded in practically every Pacific island group from the Gambiers to the Pelews—an area covering 100 degrees of longitude by 35 of latitude—everywhere welcome, but nowhere really successful. In 1893 he found himself in Sydney, none too well off, and took some stories of island life to J. F. Archibald (q.v.), then editor of the *Bulletin*, who encouraged him to write more and helped him with the writing; in 1894 a collection of these stories was published in London under the title *By Reef and Palm*. This was the first and best of a long series of novels and short-story collections dealing with the southern Pacific, many of which were written in collaboration with Walter Jeffery: *The Mutineer* (1898) which dealt with the 'Mutiny of the *Bounty*' (q.v.) was probably the best of these. Jeffery also collaborated with him in *Naval Pioneers of Australia* (1899). From 1897 to 1907 he resided in England or France, but in 1908 returned to the Pacific, living for a time at Suva in Fiji, then in New Zealand, and at last drifted back to Sydney, where he died on 18 February 1913.

Bedford, Sir Frederick George Denham (1838-1913), son of Vice-admiral E. J. Bedford, was born on 28 December 1838. He entered the royal navy in 1852, served in the Black Sea and the Baltic during the Crimean war, and became lieutenant in 1859, commander in 1871, and captain in 1876. He commanded the *Shah* in her engagement with the Peruvian ironclad *Huascar* in 1877, and as captain of H.M.S. *Monarch* in 1884 organized an armed flotilla to operate on the Nile for the relief of General Gordon. From 1889 to 1892 he was a lord of the admiralty; between 1892 and 1895 he had charge of naval operations against native chiefs on the west coast of Africa, then returning to the admiralty until 1899, and becoming commander-in-chief on the North American station until 1903. In that year he was appointed governor of Western Australia, and held the post until 1909. He died at Weybridge in Surrey on 30 January 1913. (C.B., 1886; K.C.B., 1895; G.C.B., 1902; G.C.M.G., 1909.)

Bedfordia, a genus of the family Compositae, two species of which are endemic in Australia. Its floral bracts are in a single row; disk pitted; florets without rays; fruits angular, with a pappus of slender bristles. *B. salicina* (Tasmanian Dogwood), also known as 'Cottonwood' owing to the abundant down on the leaves, is one of the few members of the family which yield a commercial timber. The wood is pale-brown and mottled, and is used for furniture. It emits a foetid smell when cut, and is exceptionally difficult to season. Fresh shavings change colour in a remarkable manner. The under-side of the leaves yields a white flock (about 1 oz. from 1 lb. of green leaves) which is obtained by means of a stiff brush or blunt knife.

Beech. This name is erroneously applied to several Australian trees, notably to *Gmelina Leichhardtii* (q.v.). The only true Australian beeches are three species of *Nothofagus* described under that heading. For the so-called brown beech see Cryptocarya; for colonial beech, Nothofagus; for evergreen beech, Cupuliferae; for Indian beech, Pongamia; for mountain beech, Lomatia; for negrohead beech, Cupuliferae or Nothofagus; and for white beech, Gmelina or Phyllanthus.

Bee-eaters. See Kingfishers and Bee-eaters.

Bee Farming. The honey bee (*Apis mellifica*) occurs in most parts of the world, but the forms found in different countries exhibit slight differences of appearance and behaviour. These some entomologists consider as distinguishing species, while others class all the forms as mere races or sub-species of *A. mellifica*.

The first reference to bees in Australian history occurs in a letter from Gregory Blaxland (1 March 1805), asking for cargo space on the *William Pitt* for a 'swarm of bees in cabin with wire cage over the hive.' There is, however, no record of their safe landing. The first record of the actual introduction of bees occurs in a letter from Samuel Marsden to the secretary of the London Missionary Society, in which he mentions that on his way back to the colony in the ship *Ann* he purchased at Rio de Janeiro two hives, which were safely landed on 27 February 1810, and placed in the garden of government house. In March 1822 Captain Wallace of the *Isabella* brought in a number of hives, and the first swarming is recorded as taking place in the following October. These 'black' or 'English' bees have since spread over the entire continent, and are now locally known as the 'bush' bee. The Italian race (*A. mellifica*, var. *ligustica*) was introduced between the years 1874 and 1878, and the so-called 'hybrid' is a cross between the black and the Italian races. The Italians, and even the hybrids, have shown themselves so far superior to the black bee as honey-makers that the great majority of bee-keepers consider all discussion of the matter at an end. Italians—where the race is still pure and not enfeebled by interbreeding with light-coloured bees—are superior to any other kind, and may be safely recommended to those who propose to keep bees, either as a commercial proposition or merely as a hobby.

Australia, with its widespread eucalypt-forests, offers an excellent field for bee-farming; for eucalyptus flowers provide both nectar and pollen in abundance, and from them nearly all our honey is obtained. Other important honey-producing plants are the prickly pear—which now overruns large areas in Queensland and New South Wales; lucerne (especially on river flats in New South Wales, where it is raised for seed); and the clovers, which are chiefly grown in Victoria and Tasmania. Another widely-distributed group of trees—the wattles, or acacias—although not nectar-yielding, supply large quantities of pollen in the early spring, when the bees most require it for the purpose of rearing their broods.

City flower-gardens, though of no use to the bee-farmer on a large scale, help the town-dweller with his one or two hives; most garden flowers yield nectar and pollen, but it takes a large area of plants to provide a really adequate supply. Near the cities, however, 30 or 40 lb. per bee-colony is considered a fair return. The most productive garden-flowers are the Labiatae

(rosemary, thyme, lavender, and salvia), as well as stocks, lupins, sunflowers, gaillardias, mignonette, honeysuckle, freesias, and lilies.

From the rich and varied Australian flora very large yields of honey are often obtained, of which the apicultural journals contain authentic records; a Victorian grower obtained 824 lb. and 807 lb. from two hives, exclusive of the weight of honey removed when uncapping.

Victoria is the only State that has any legislation dealing with bee-pasture. The forest department administers the act. A bee-farm site is an area (up to 10 acres) on which to place the bees. A bee range is an area of a mile radius (with the bee-farm in the centre) to be used as a foraging ground. The bee-farmer rents the tops of the trees only; he has no right over the grass or land. In the other States a prospective bee-farmer, after deciding on a suitable district, generally purchases or rents a small area on which to place his hives, extracting house, etc., after previously ascertaining (in his own interests) that he is at least two miles from any other apiary. To prevent horses or cattle from molesting the bees, it is advisable to fence the area. But, if sheep are grazing in the neighbourhood, it is a good plan to let them have free range of the apiary, to keep down the grass.

The methods of securing a honey crop may be obtained from textbooks dealing especially with Australian conditions. One or two points of general interest, however, may be mentioned. Owing to the genial climate the bee-farmer can dispense with the elaborate precautions—such as winter packing, chaff hives, and underground cellars—that are required in colder countries. Here the bees can remain on their summer stands, though spare supers should be removed, and the hive-entrances made smaller. In a district liable to frosts a few thicknesses of newspaper, placed on the frames under the mat, will keep the bees snug and warm. In early summer bees exhibit a tendency to swarm, which must be restricted to the utmost, as it divides the strength of a colony just when it is most wanted. With care and attention to modern methods swarming can be greatly reduced, if not altogether prevented. When the swarming impulse ceases, the bees settle down to steady work, and the bee-farmer, relieved of much worry, is able to devote more time to the commercial side of his business.

The old idea that bee-farming is easy, and that the farmer has only to wait until the hives are full of honey and then extract it, has gone by the board. Modern appliances have simplified work in the apiary, but have also increased it, and have both enabled and compelled the apiarist to deal more scientifically with his business.

The native bee (*Trigona*) produces a honey with very distinctive qualities, alleged by some naturalists to be antiseptic and anti-malarial. At one time it was bought up for exportation to France, and there realized from two to three shillings per pound, one small consignment even reaching 4s. 6d. When properly separated from the cells in which it is stored, *Trigona* honey is exceptionally delicious. But native bees must not be kept near hives of any imported species, as they at once devote themselves to robbing their neighbours instead of collecting their own supplies. If kept well apart, they are assiduous honey-makers, and their small size (not greater than a house-fly's) allows them to visit many sources of nectar that the larger imported species leave alone.

The returns of honey from productive hives during the 1922-3 season (the latest available) gave an average of 58¼ lb. per hive. The reported yield of 1917-8 averaged nearly 76 lb., but this was abnormal: the probable explanation is that, when in 1917 the price of honey suddenly doubled, quantities of previously stored honey were put on the market and so found their way into official statistics. In 1919-20 the yield was very low, but 1920-1—judging by a fairly long average of years—may be taken as normal. The figures for the last four seasons yet published are:—

		HONEY.		BEESWAX.	
		Product	Exports	Product	Net imports
1919-20	(Amount, lb.)	3,144,280	588,384	60,435	10,296
	(Value, £.)		18,815		502
1920-21	(Amount, lb.)	5,651,143	97,541	78,181	20,700
	(Value, £.)		5,328		1,642
1921-22	(Amount, lb.)	7,370,790	94,471	84,417	221,182
	(Value, £.)		4,448		12,362
1922-23	(Amount, lb.)	6,369,062	57,638	90,494	238,368
	(Value, £.)		2,718		13,817

The wax yield in 1922-3 was 13 oz. per hive. Australia exports honey but imports beeswax, owing to the general use of frame hives.

H.H.

Beef-wood, a name applied to several quite unconnected Australian trees, resembling each other in the red colour of their timber. See CASUARINA and STENOCARPUS. For western beef-wood, see GREVILLEA.

Bees, insects of the group Anthophila and order Hymenoptera, which is well represented in Australia, no less than 872 species being recorded in the latest catalogue; of these the Prosopididae claim nearly 300, and the Colletidae, Andrenidae, and Megachilidae more than 100 each. The Colletidae are moderate-sized, short-tongued and very hairy. Our best-known genus is *Paracolletes*. The Prosopididae, also short-tongued, are smaller and smooth. Both these families contain mostly black or brown species, though some are strikingly marked—e.g. the wasp-like *Hyleoides concinna*, which has bright red marks on the face and abdomen. *Prosopis* is often to be found in swarms round flowering shrubs in the bush.

All the other families are long-tongued. The Andrenidae are burrowing bees; the commonest genus in Australia is *Halictus*. *Nomia australica* and *Parasphecodes leptospermi* are well-known visitants to the flowers of the tea-tree.

The Megachilidae (leaf-cutting bees) are represented by numerous species of the great genus *Megachile*, noted for their habit of cutting out of leaves circular pieces to be used for lining their nests. *M. mystacea* is shown on plate xix, fig. 41.

The large, stout carpenter bees (Xylocopidae)

bore holes in the stems of plants; the best-known of them are the bright metallic-green species of the genus *Lestis*, and the very large and handsome *Mesotrichia bryorum*.

The Anthophoridae are banded brown or fulvous; fewer than 20 species of this family are known in Australia. The handsome *Anthophora bombiformis* is shown on plate xix, fig. 42. Of the other families, the Melectidae are represented by the handsome genus *Crocisa*; the Ceratinidae by the well-known *Allodape* and *Exoneura*; and the true honey-bees (Apidae) by a few species of *Apis* and *Trigona*. The honey-bee of Europe (*Apis mellifica*) has become firmly established in a wild state throughout most parts of the Commonwealth. Of the true native bee (*Trigona*) nine species are at present known; they are small, mostly black in colour, and not endowed with stings. They may be found in all parts of Australia, in communities often numbering many thousands, occupying cavities in the trunks or branches of dead trees. These cavities may be in a hollow trunk only a few feet from the ground, but more usually occur near the top of a tall eucalypt; entrance is obtained through a small hole or crevice, which the bees make still smaller, until only one bee can enter at a time. *Trigona* makes no comb, but stores its honey in an irregular mass of pod-shaped receptacles with a hollow centre; in this hollow is built up a pyramid of saucers, and in these the young are reared. The wax is chocolate in colour. Several quarts of honey may be obtained from a single nest, but only at the cost of destroying a number of bees out of all proportion to the yield. The aborigines prized the honey greatly and invented many ingenious ways of procuring it. See HYMENOPTERA and BEE FARMING. R.J.T.

Beetles, vernacular name of a very large order (Coleoptera) of insects, whose distinguishing character is that (except in a very few cases) the fore-wings (elytra) are horny and used as protective coverings for the hind-wings. In a few families the elytra are soft; in others the hind-wings are absent, or so much reduced as to be useless for flight, the wing-cases being then united along the middle to form a single casing. These flightless groups occur in many families—e.g. the Broscinae among the Carabidae, many Helaeinae among the Tenebrionidae, the Amycterinae among the weevils. In a few cases apterous species occur in a genus usually winged (e.g., *Telephorus, Natalis*), and still more rarely the male is winged and the female apterous. All beetles undergo complete metamorphosis from the egg through larva and pupa to the imago. Most are vegetarians throughout life, though a few completely change their food when they attain maturity; some species are carnivorous.

The life-histories of Australian beetles have —with very few exceptions—been little studied, and should provide much important work for students. The correlation of our genera with the world-system also requires the attention of entomologists. Many of our beetles show a marked divergence from those of other countries; whole groups, and many genera, occur nowhere else. This is especially true of those from the central and western areas, and of apterous forms like the larger fossorial Carabidae, the hard-shelled ground-weevils, and the many striking Helaeinae.

The northern and eastern coast-regions have a considerable admixture of genera (and even of species) found also in Papua and Malaysia; a few extend to Fiji, New Zealand, and other Pacific islands. *Tricondyla aptera, Setenis sulcigera, Glenea picta, Sipalus gigas* are notable examples of species found on both sides of Torres Straits. The interesting Broscinae of the Carabidae find their nearest allies in South America, whereas the tiger-beetles of the genus *Megacephala* have close relations in both Africa and America. The cosmopolitan species, introduced through commerce—few in species but disastrously numerous in individuals—are notorious grain and store pests.

More than 15,000 species, belonging to about 2250 genera and 67 families, have been recorded from Australia. The following families—arranged on a plan modified from that of modern authors such as Ganglbauer, Handlirsch, and Lameere—contain the great majority of the species:—

Sub-order ADEPHAGA.

Families	Cicindelidae (tiger-beetles) Carabidae (ground-beetles) Dytiscidae (water-beetles) Gyrinidae (whirligig-beetles) Paussidae

Sub-order POLYPHAGA.

Group	Families
Palpicornia	Hydrophilidae (water-beetles)
Staphyliniformia	Staphylinidae (rove-beetles) Pselaphidae Silphidae (carrion-beetles) Histeridae
Malacodermata	Malacodermidae Cleridae
Clavicornia	Colydiidae Cucujidae Nitidulidae Erotylidae Coccinellidae (ladybirds) Byrrhidae (pill-beetles)
Sternoxia	Elateridae (click-beetles) Buprestidae (jewel-beetles)
Heteromera	Tenebrionidae Cistelidae Anthicidae Mordellidae Cantharidae (blister-beetles) Oedemeridae
Phytophaga	Chrysomelidae Cerambycidae (longicorns)
Rhynchophora	Curculionidae (weevils) Scolytidae Brenthidae Anthribidae
Lamellicornia	Lucanidae (stag-beetles) Scarabaeidae (chafers)

Twelve species are figured on plate ix, and thirteen on plate xi. References in this article are to plate xi.

The sub-order Adephaga—in which the first ventral segment is divided by the hind coxal cavities, and the hind-wing has one or two cross-veins near the middle—consists in general of carnivorous and predatory beetles, most with filiform antennae, and terrestrial, arboreal, or aquatic in habit. It includes the families Cicindelidae, Carabidae, Dytiscidae, Gyrinidae, and possibly Paussidae.

The Cicindelidae (tiger-beetles), with about 70 species, are active, predaceous insects found

more commonly in the tropical areas, but scarce in the south and absent from Tasmania. Species of *Distypsidera* run about tree-stems in the coastal districts of Queensland and northern New South Wales. The brilliantly-coloured *Megacephala*, found in the central and northern areas, are nocturnal in habit. *Cicindela* includes many of the smaller species. The silvery *C. ypsilon* may be seen on the sandy sea-beaches of eastern Australia. *Nickerlea Sloanei*, a western species, combines the habit and appearance of *Cicindela* with the mouth-parts of *Distypsidera*. The Carabidae (ground-beetles) are represented by some 1500 species contained in about 200 genera. Of the seven sub-families the Lebiinae—small, flat, brown beetles with red or black markings—are extraordinarily abundant under the loose bark of trees. The genus *Carenum* (of the Scaritinae), of burrowing habits and often of brilliant lustre, is peculiar to Australia. The genera *Silphomorpha* and *Adelotopus* (of the Pseudomorphinae), also found under bark, are remarkable for their oval form, short legs, and active habits. The Feroninae comprise large species very abundant in eastern Australia, *Homalosoma* and *Catadromus* containing especially fine examples. The Helluoninae are unusually numerous in Australia, the genera *Gigadema* and *Helluarchus* containing very large species; those of *Aenigma* are brilliantly metallic. The Cnemacanthinae are very numerous, and the genus *Promecoderus* is widely distributed; the extremes of size are to be noted in the extraordinarily elongate *Hyperion Schroetteri* (in which the hind-legs are placed unusually far back) and the minute blind species of *Illaphanus* —the former living in rotten pipes of the larger eucalypts of eastern Australia, the latter to be found by a keen eye under deeply embedded stones in New South Wales and Tasmania. The Pamborinae (eastern) and Cuncipectinae (western) are the only sub-families confined to Australia. The bombardier beetle *Pheropsophus verticalis*, black with red spots, is a noteworthy and widespread member of the Carabidae.

The Dytiscidae (170 species) are flat, oval, smooth water-beetles of voracious habits, with legs adapted for swimming, and elytra enclosing air for sub-aqueous breathing; they are mostly dark in colour, with paler spots or stripes. *Sternopriscus* is a distinctive genus, its many minute species having curious antennae and legs. *Eretes australis* occurs in countless numbers in most waterholes and creeks 'out back,' and forms an important part of the diet of aquatic birds.

The Gyrinidae (whirligig-beetles) are often seen darting about in companies on the surface of fresh water. They have short antennae and long front-legs, especially in the male the other legs being flattened into paddles. All have four eyes, enabling them to detect enemies (or food) in water or air. About 30 species are recorded, all of genera which range beyond Australia.

The Paussidae are a curious family of doubtful position, but with ventral segments as in other Adephaga. The species, some 50 in number (mostly of the genus *Arthropterus*), have wide, flat legs, widely laminate antennae, and membranous elytra-tips. These beetles are able to bombard; they are attracted to light; some live in ants' nests, but *A. brevis* occurs, sometimes in colonies, under eucalypt bark, or in crevices of decaying logs in New South Wales. *Megalopaussus amplipennis* is the largest of our species. Besides Australia this family is found chiefly in Africa and Asia; a few are known in Europe, and one species occurs in Brazil.

The sub-order Polyphaga includes the remaining groups, distinguished from the Adephaga because the first ventral segment is not divided by the hind coxal cavities, and the wings are not cross-veined near the middle. There are nine chief groups, comprising 29 families.

The group Palpicornia includes convex water-beetles of the family Hydrophilidae, with 6-9 jointed antennae and curiously modified palpi, often of great length, and five tarsi on each leg. More than 100 species have been recorded, of varied size, but generally of dark colour. As with the Gyrinidae they often take flight, and are attracted to strong light; *Pseudohydrobius floricola* is found on flowers.

The group Staphyliniformia—with short elytra that expose much of the abdomen—includes four families. The Staphylinidae (rove-beetles) contain nearly 600 Australian species of 100 genera. They have a mobile abdomen with apical appendages, and are found in decaying animal or vegetable matter, whereas *Dabra* and others occur in ants' nests and the Omalinae on flowers. *Conosoma* occurs under bark or with ants, *Creophilus* and *Philonthus* are scavengers, *Cafius* haunts decaying seaweed, and *Sartallus* fish-refuse. *Metoponcus*, with its pleasant scent, lives under the bark of native figs and sassafras; *Stenus coeruleus* occurs on foliage in the eastern brush forests. *Cryptommatus jansoni* is recorded as inhabiting the base of the tail of Tasmanian rats.

The Pselaphidae are small reddish beetles, with clubbed antennae, often found in nests of ants or termites, or in moss or vegetable debris. They feed on mites and other minute creatures, and often possess curiously-formed antennae and palpi, with marked sexual differences. The tarsi are 3-jointed. About 360 species are recorded from Australia. The sub-family Clavigerinae is represented by two genera, *Clavigeropsis* and *Articeros*; the former consists of two species, one Abyssinian, the other Australian. The many species of *Articeros* (now regarded as confined to Australia) have 2-jointed antennae, and tufts of hair on the abdomen which secrete a fluid that is greatly appreciated by ants. The Silphidae (carrion-beetles) comprise some 40 species; *Ptomaphila lachrymosa*, a large species, is found on carrion; the species of *Myrmicholeva* are inquilines in ants' nests. The Histeridae (over 100 species), generally flat, with a hard polished black surface, occur in decaying vegetable or animal matter. Species of *Hololepta* are found in rotting *Xanthorrhoea* stems from Perth to Sydney, often in company with *Platysoma* or *Acritus*; *Saprinus* occurs in carcases. An interesting race—*Chlamydopsis* and its allies—which has recently been investigated by A. M. Lea, inhabits ants' nests, having protective armour and retractile appendages.

The group Malacodermata includes two families of soft-skinned beetles with 5-jointed tarsi, abundant in summer on flowers and foliage. The Malacodermidae (400 Australian species) have long serrated antennae. The red or black species of *Metriorrhynchus* occur in profusion, some having a long rostrum like that of weevils. They are distasteful to birds, and hence appear to be closely mimicked by corresponding species and varieties of *Pseudolychus* (of the Oedemeridae). The genera *Carphurus*, *Balanophorus*, and *Laius*, numerous in species, possess extrusible vesicles. The small fire-flies *Luciola* and *Aty-*

phella—the apical segments of whose abdomina are phosphorescent—are mostly found in the warmer areas of the eastern coast. *A. lychnus* is to be seen among tree-ferns on the Blue Mountains. The Cleridae comprise 300 species of small and graceful flower-frequenting beetles, often of beautiful colour; most belong to the genera *Lemidia, Phlogistus,* and *Elecale.* Of predacious habits, their larvae are active. *Cylidrus* species feed on scolytid larvae and other bark-borers; *Stigmatium, Omadius,* and *Natalis* live under bark. The last-mentioned genus contains the giants of the family, *N. titana* measuring up to two inches in length.

The group Clavicornia is heterogeneous; its members have clubbed antennae and, usually, 5-jointed tarsi, but in Coccinellidae they are 4-jointed. The group includes six families. The Colydiidae and Cucujidae (each with about 100 recorded Australian species) live mostly under bark. The former are, in general, black and cylindrical, the latter mostly red or brown and very flat. *Eutermicola sculpticollis* occurs only in the nests of termites, *Nepharis alata* in those of ants. *Hectarthrum brevifossum* (of the Cucujidae) is remarkable for its wide distribution and great variation in size. The Nitidulidae (about 100 species from Australia) are small, flat beetles, often with shortened elytra; many occur in over-ripe fruit, in fungi or decaying vegetation. One species of *Brachypeplus* occurs in *Xanthorrhoea,* another in *Macrozamia,* and a third—*B. auritus*—in the nests of the native bee. The Erotylidae are fungus beetles, of elongate form and hard surface, with variously ornamental patterns. *Episcaphula hercules,* from northern Queensland, is the largest. The Coccinellidae (ladybirds), many of whose genera are of world-wide distribution, are noted for their economic uses in keeping down scale-insects and aphides in gardens and orchards. Some 300 Australian species are known. This family was by earlier authors included under Trimera, being supposed to have only three tarsi on each foot. *Rhizobius, Scymnus,* and *Orcus* are very numerous in species. The Byrrhidae (pill-beetles), a small family of little spherical beetles, includes the beautiful metallic species of *Pedilophorus* found in Tasmanian moss (fig. 6).

The group Sternoxia is a numerous tribe of elongate, hard-skinned beetles with a specially-constructed prosternum; the most important families are the two following. The Elateridae (click-beetles) have the pro-sternal process so fitted into the mesosternum as to enable the insect to jump with a jerk. The larvae of some species are the garden pests known as wire-worms. Above 500 species are recorded, mostly of dark colour, as in *Lacon* and *Monocrepidius;* but the species of *Cardiophorus* and *Ophidius*—found on flowers or foliage—are often ornamented with patterns. The largest species occur in *Tetralobus* (with pectinated antennae) and *Haus* (with lichen-like markings). The Buprestidae (with 760 species of 44 genera) contain the gems of our insect world, their brilliant colour and horny covering making some species suitable for mounting as jewellery. The larvae (see WOOD-BORERS) tunnel stems or roots of trees, and may be recognized by their swollen thorax. The beautiful endemic genera *Stigmodera* (fig. 7), *Curis, Neocuris* and the tropical *Calodema* and *Metaxymorpha* are found on flowers—especially of the honey-bearing eucalypts and of *Leptospermum;* the Chalcophorinae, *Nascio* and *Cisseis* are chiefly found on foliage. *Astraeus* and *Germarica* are associated with casuarina trees; *Melobasis* usually with acacias; *Diadoxus* with pines; *Cyria* with banksias. The curious and active *Xyroscelis crocata* is found on *Macrozamia* cycads as far apart as Perth and Sydney. All are winged, and many have strong powers of flight.

The group Heteromera, members of which have four tarsal joints on the hind and five on the anterior and middle feet, includes six families. The Tenebrionidae are a large and multiform family of nearly 1000 Australian species contained in 150 genera. Winged or apterous, they are chiefly nocturnal, and found by day in or under rotting timber, leaves, or under bark. In size they vary from the bead-like *Trachyscelis* of the sandy beaches to the large and brilliant Cyphaleinae. The Boletophaginae (*Mychestes* and its allies) are fungus-eaters; *Byrsax macleayi* is remarkable for its strong, musky smell. Peculiar endemic groups are the Helaeinae and Nyctozoilinae (mostly apterous), which are widely spread over the whole continent, and are especially characteristic of the dry inland regions. In *Helacus* the head is completely surrounded by the curiously wide-flanged pro-thorax. The 80 winged species of *Pterohelaeus* are bark-dwellers. *Adelium* and its allies are ground-beetles, numerous and widespread, *Cardiothorax* being confined to the eastern States. The Torresian fauna is largely represented by the Cyphaleinae and Amarygminae, generally of metallic form, ranging from Australia to India. *Menephilus, Meneristes,* and *Hypaulax*—all found in decaying timber—are typical Tenebrioninae. The Cistelidae are a rather fragile family of 140 species, separated from the preceding by the pectinate claws and lamellate tarsi. The metallic *Aethyssius* and the duller *Chromomoca* and *Homotrysis,* with their allies, include the majority of the species. The Anthicidae are ant-like and very active beetles, of which about 120 species are recorded from Australia, largely of the genera *Anthicus* and *Formicomus. Lemodes* (fig. 9), velvety red, sometimes with blue markings—which was formerly classed under Pyrochroidae—and *Trichananca* are confined to Australia. *Mecynotarsus* (often found on sea-beaches) has a curious crest projecting over the head. The Mordellidae (100 species) are active, triangular beetles, mostly of small size, that frequent flowers and are remarkable as jumpers. The allied Rhipiphoridae contain fewer species of larger size, the males of which have fan-like antennae. The Cantharidae (blister-beetles) comprise 80 Australian species, mostly of the beautiful genus *Zonitis.* The rare *Goetymes* and *Sitarida* have curiously abbreviated elytra. The Oedemeridae (about 60 species) have elongate bodies, with soft integument, often closely resembling the malacoderms. *Pseudolychus, Copidita,* and *Oxacis* are numerous in species and wide in range. The male of *Dohrnia miranda* has singular antennae, and the red-and-blue *Agasma semicrudum* is the giant of the family.

The group Phytophaga is by its name strictly a leaf-feeding group, and should therefore contain the Chrysomelidae only; but it is usually considered as including the Cerambycidae also, their tarsi (apparently four on each foot, but really five, since the fourth is a mere nodule) resembling those of the former family. The Cerambycidae (longicorns) are elongate beetles with unusually long antennae, notorious as timber-borers (see WOOD-BORERS) and often possessing strong powers of flight. Some 800 species, contained in more than 200 genera and three sub-families, have been recorded from Australia. Of these the Prioninae

more commonly in the tropical areas, but scarce in the south and absent from Tasmania. Species of *Distypsidera* run about tree-stems in the coastal districts of Queensland and northern New South Wales. The brilliantly-coloured *Megacephala*, found in the central and northern areas, are nocturnal in habit. *Cicindela* includes many of the smaller species. The silvery *C. ypsilon* may be seen on the sandy sea-beaches of eastern Australia. *Nickerlea Sloanei*, a western species, combines the habit and appearance of *Cicindela* with the mouth-parts of *Distypsidera*. The Carabidae (ground-beetles) are represented by some 1500 species contained in about 200 genera. Of the seven sub-families the Lebiinae—small, flat, brown beetles with red or black markings—are extraordinarily abundant under the loose bark of trees. The genus *Carenum* (of the Scaritinae), of burrowing habits and often of brilliant lustre, is peculiar to Australia. The genera *Silphomorpha* and *Adelotopus* (of the Pseudomorphinae), also found under bark, are remarkable for their oval form, short legs, and active habits. The Feroninae comprise large species very abundant in eastern Australia, *Homalosoma* and *Catadromus* containing especially fine examples. The Helluoninae are unusually numerous in Australia, the genera *Gigadema* and *Helluarchus* containing very large species; those of *Aenigma* are brilliantly metallic. The Cnemacanthinae are very numerous, and the genus *Promecoderus* is widely distributed; the extremes of size are to be noted in the extraordinarily elongate *Hyperion Schroetteri* (in which the hind-legs are placed unusually far back) and the minute blind species of *Illaphanus* —the former living in rotten pipes of the larger eucalypts of eastern Australia, the latter to be found by a keen eye under deeply embedded stones in New South Wales and Tasmania. The Pamborinae (eastern) and Cuncipectinae (western) are the only sub-families confined to Australia. The bombardier beetle *Pheropsophus verticalis*, black with red spots, is a noteworthy and widespread member of the Carabidae.

The Dytiscidae (170 species) are flat, oval, smooth water-beetles of voracious habits, with legs adapted for swimming, and elytra enclosing air for sub-aqueous breathing; they are mostly dark in colour, with paler spots or stripes. *Sternopriscus* is a distinctive genus, its many minute species having curious antennae and legs. *Eretes australis* occurs in countless numbers in most waterholes and creeks 'out back,' and forms an important part of the diet of aquatic birds.

The Gyrinidae (whirligig-beetles) are often seen darting about in companies on the surface of fresh water. They have short antennae and long front-legs, especially in the male the other legs being flattened into paddles. All have four eyes, enabling them to detect enemies (or food) in water or air. About 30 species are recorded, all of genera which range beyond Australia.

The Paussidae are a curious family of doubtful position, but with ventral segments as in other Adephaga. The species, some 50 in number (mostly of the genus *Arthropterus*), have wide, flat legs, widely laminate antennae, and membranous elytra-tips. These beetles are able to bombard; they are attracted to light; some live in ants' nests, but *A. brevis* occurs, sometimes in colonies, under eucalypt bark, or in crevices of decaying logs in New South Wales. *Megalopaussus amplipennis* is the largest of our species. Besides Australia this family is found chiefly in Africa and Asia; a few are known in Europe, and one species occurs in Brazil.

The sub-order Polyphaga includes the remaining groups, distinguished from the Adephaga because the first ventral segment is not divided by the hind coxal cavities, and the wings are not cross-veined near the middle. There are nine chief groups, comprising 29 families.

The group Palpicornia includes convex water-beetles of the family Hydrophilidae, with 6-9 jointed antennae and curiously modified palpi, often of great length, and five tarsi on each leg. More than 100 species have been recorded, of varied size, but generally of dark colour. As with the Gyrinidae they often take flight, and are attracted to strong light; *Pseudohydrobius floricola* is found on flowers.

The group Staphyliniformia—with short elytra that expose much of the abdomen—includes four families. The Staphylinidae (rove-beetles) contain nearly 600 Australian species of 100 genera. They have a mobile abdomen with apical appendages, and are found in decaying animal or vegetable matter, whereas *Dabra* and others occur in ants' nests and the Omalinae on flowers. *Conosoma* occurs under bark or with ants, *Creophilus* and *Philonthus* are scavengers, *Cafius* haunts decaying seaweed, and *Sartallus* fish-refuse. *Metoponcus*, with its pleasant scent, lives under the bark of native figs and sassafras; *Stenus coeruleus* occurs on foliage in the eastern brush forests. *Cryptommatus jansoni* is recorded as inhabiting the base of the tail of Tasmanian rats.

The Pselaphidae are small reddish beetles, with clubbed antennae, often found in nests of ants or termites, or in moss or vegetable debris. They feed on mites and other minute creatures, and often possess curiously-formed antennae and palpi, with marked sexual differences. The tarsi are 3-jointed. About 360 species are recorded from Australia. The sub-family Clavigerinae is represented by two genera, *Clavigeropsis* and *Articeros*; the former consists of two species, one Abyssinian, the other Australian. The many species of *Articeros* (now regarded as confined to Australia) have 2-jointed antennae, and tufts of hair on the abdomen which secrete a fluid that is greatly appreciated by ants. The Silphidae (carrion-beetles) comprise some 40 species; *Ptomaphila lachrymosa*, a large species, is found on carrion; the species of *Myrmicholeva* are inquilines in ants' nests. The Histeridae (over 100 species), generally flat, with a hard polished black surface, occur in decaying vegetable or animal matter. Species of *Hololepta* are found in rotting *Xanthorrhoea* stems from Perth to Sydney, often in company with *Platysoma* or *Acritus*; *Saprinus* occurs in carcases. An interesting race—*Chlamydopsis* and its allies—which has recently been investigated by A. M. Lea, inhabits ants' nests, having protective armour and retractile appendages.

The group Malacodermata includes two families of soft-skinned beetles with 5-jointed tarsi, abundant in summer on flowers and foliage. The Malacodermidae (400 Australian species) have long serrated antennae. The red or black species of *Metriorrhynchus* occur in profusion, some having a long rostrum like that of weevils. They are distasteful to birds, and hence appear to be closely mimicked by corresponding species and varieties of *Pseudolychus* (of the Oedemeridae). The genera *Carphurus*, *Balanophorus*, and *Laius*, numerous in species, possess extrusible vesicles. The small fire-flies *Luciola* and *Aty-*

phella—the apical segments of whose abdomina are phosphorescent—are mostly found in the warmer areas of the eastern coast. *A. lychnus* is to be seen among tree-ferns on the Blue Mountains. The Cleridae comprise 300 species of small and graceful flower-frequenting beetles, often of beautiful colour; most belong to the genera *Lemidia*, *Phlogistus*, and *Elcale*. Of predacious habits, their larvae are active. *Cylidrus* species feed on scolytid larvae and other bark-borers; *Stigmatium*, *Omadius*, and *Natalis* live under bark. The last-mentioned genus contains the giants of the family, *N. titana* measuring up to two inches in length.

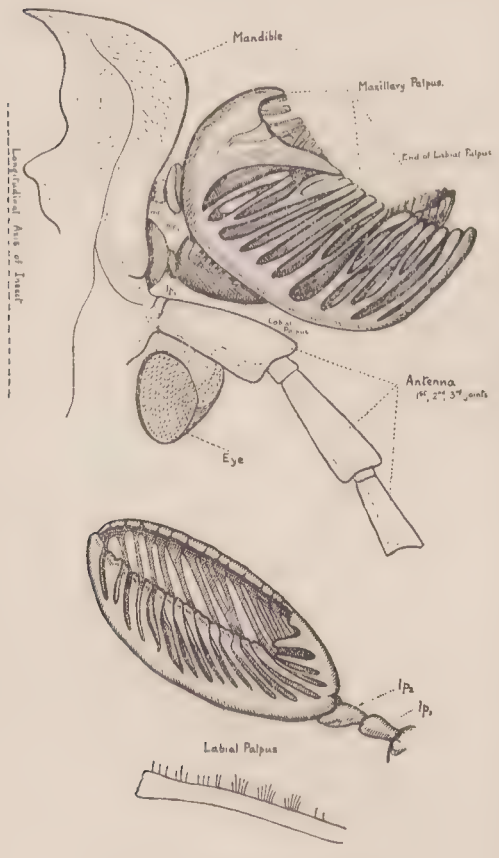
The group Clavicornia is heterogeneous; its members have clubbed antennae and, usually, 5-jointed tarsi, but in Coccinellidae they are 4-jointed. The group includes six families. The Colydiidae and Cucujidae (each with about 100 recorded Australian species) live mostly under bark. The former are, in general, black and cylindrical, the latter mostly red or brown and very flat. *Eutermicola sculpticollis* occurs only in the nests of termites, *Nepharis alata* in those of ants. *Hectarthrum brevifossum* (of the Cucujidae) is remarkable for its wide distribution and great variation in size. The Nitidulidae (about 100 species from Australia) are small, flat beetles, often with shortened elytra; many occur in over-ripe fruit, in fungi or decaying vegetation. One species of *Brachypeplus* occurs in *Xanthorrhoea*, another in *Macrozamia*, and a third—*B. auritus*—in the nests of the native bee. The Erotylidae are fungus beetles, of elongate form and hard surface, with variously ornamental patterns. *Episcaphula hercules*, from northern Queensland, is the largest. The Coccinellidae (ladybirds), many of whose genera are of world-wide distribution, are noted for their economic uses in keeping down scale-insects and aphides in gardens and orchards. Some 300 Australian species are known. This family was by earlier authors included under Trimera, being supposed to have only three tarsi on each foot. *Rhizobius*, *Scymnus*, and *Orcus* are very numerous in species. The Byrrhidae (pill-beetles), a small family of little spherical beetles, includes the beautiful metallic species of *Pedilophorus* found in Tasmanian moss (fig. 6).

The group Sternoxia is a numerous tribe of elongate, hard-skinned beetles with a specially-constructed prosternum; the most important families are the two following. The Elateridae (click-beetles) have the pro-sternal process so fitted into the mesosternum as to enable the insect to jump with a jerk. The larvae of some species are the garden pests known as wire-worms. Above 500 species are recorded, mostly of dark colour, as in *Lacon* and *Monocrepidius;* but the species of *Cardiophorus* and *Ophidius*—found on flowers or foliage—are often ornamented with patterns. The largest species occur in *Tetralobus* (with pectinated antennae) and *Alaus* (with lichen-like markings). The Buprestidae (with 760 species of 44 genera) contain the gems of our insect world, their brilliant colour and horny covering making some species suitable for mounting as jewellery. The larvae (see WOOD-BORERS) tunnel stems or roots of trees, and may be recognized by their swollen thorax. The beautiful endemic genera *Stigmodera* (fig. 7), *Curis*, *Neocuris* and the tropical *Calodema* and *Metaxymorpha* are found on flowers—especially of the honey-bearing eucalypts and of *Leptospermum;* the Chalcophorinae, *Nascio* and *Cisseis* are chiefly found on foliage. *Astraeus* and *Germarica* are associated with casuarina trees; *Melobasis* usually with acacias; *Diadoxus* with pines; *Cyria* with banksias. The curious and active *Xyroscelis crocata* is found on *Macrozamia* cycads as far apart as Perth and Sydney. All are winged, and many have strong powers of flight.

The group Heteromera, members of which have four tarsal joints on the hind and five on the anterior and middle feet, includes six families. The Tenebrionidae are a large and multiform family of nearly 1000 Australian species contained in 150 genera. Winged or apterous, they are chiefly nocturnal, and found by day in or under rotting timber, leaves, or under bark. In size they vary from the bead-like *Trachyscelis* of the sandy beaches to the large and brilliant Cyphalcinae. The Boletophaginae (*Mychestes* and its allies) are fungus-eaters; *Byrsax macleayi* is remarkable for its strong, musky smell. Peculiar endemic groups are the Helaeinae and Nyctozoilinae (mostly apterous), which are widely spread over the whole continent, and are especially characteristic of the dry inland regions. In *Helaeus* the head is completely surrounded by the curiously wide-flanged pro-thorax. The 80 winged species of *Pterohelaeus* are bark-dwellers. *Adelium* and its allies are ground-beetles, numerous and widespread, *Cardiothorax* being confined to the eastern States. The Torresian fauna is largely represented by the Cyphalcinae and Amarygminae, generally of metallic form, ranging from Australia to India. *Menephilus*, *Meneristes*, and *Hypaulax*—all found in decaying timber—are typical Tenebrioninae. The Cistelidae are a rather fragile family of 140 species, separated from the preceding by the pectinate claws and lamellate tarsi. The metallic *Aethyssius* and the duller *Chromomoca* and *Homotrysis*, with their allies, include the majority of the species. The Anthicidae are ant-like and very active beetles, of which about 120 species are recorded from Australia, largely of the genera *Anthicus* and *Formicomus*. *Lemodes* (fig. 9), velvety red, sometimes with blue markings—which was formerly classed under Pyrochroidae—and *Trichananca* are confined to Australia. *Mecynotarsus* (often found on sea-beaches) has a curious crest projecting over the head. The Mordellidae (100 species) are active, triangular beetles, mostly of small size, that frequent flowers and are remarkable as jumpers. The allied Rhipiphoridae contain fewer species of larger size, the males of which have fan-like antennae. The Cantharidae (blister-beetles) comprise 80 Australian species, mostly of the beautiful genus *Zonitis*. The rare *Goetymes* and *Sitarida* have curiously abbreviated elytra. The Oedemeridae (about 60 species) have elongate bodies, with soft integument, often closely resembling the malacoderms. *Pseudolychus*, *Copidita*, and *Oxacis* are numerous in species and wide in range. The male of *Dohrnia miranda* has singular antennae, and the red-and-blue *Agasma semicrudum* is the giant of the family.

The group Phytophaga is by its name strictly a leaf-feeding group, and should therefore contain the Chrysomelidae only; but it is usually considered as including the Cerambycidae also, their tarsi (apparently four on each foot, but really five, since the fourth is a mere nodule) resembling those of the former family. The Cerambycidae (longicorns) are elongate beetles with unusually long antennae, notorious as timber-borers (see WOOD-BORERS) and often possessing strong powers of flight. Some 800 species, contained in more than 200 genera and three sub-families, have been recorded from Australia. Of these the Prioninae

are large brown beetles, whose larvae form a favourite diet of the aborigines. *Tillyardia mirabilis*, the most wonderful of the group, has palpi of unique (basket-like) form. The Cerambycinae contain smaller species of varied form and beautiful markings and colour. *Pseudocephalus* is ant-like; *Hesthesis* mimics the wasps. *Distichocera* shows great sexual differences; *Pterostenus, Syllitus,* and others give out a scent like carbolic oil, and are consequently distasteful to birds. The Lamiinae include the finest of the longicorns, many of which are true members of the Torresian fauna—e.g. *Glenea, Batocera,*



Palpi of *Tillyardia mirabilis*.

Monohammus, Olenecamptus, Gnoma; these are also found throughout Malaysia to India. *Microtragus* and *Athemistus* are apterous, found on or under logs or dead leaves. *Ancita, Zygocera, Symphyletes,* and *Rhytiphora* (fig. 12), are important genera with a wide distribution. The Chrysomelidae are an extensive family; nearly 1800 Australian species have been described. The Sagrinae are the giants of the family; in this sub-family half the Australian genera are endemic, *Megamerus* and *Polyoptilus* being richest in species. The Cryptocephalinae, of small size and beautiful colours, present strong sexual differences. *Ditropidus,* of globular form, is the largest genus. The Eumolpinae contain many pretty species of *Edusa* and its allies, as well as the two lovely species of *Spilopyra.* The Chrysomelinae include genera that range beyond Australia, and contain gems of the insect world like *Aesernia* (fig. 10), *Augomela, Phyllocharis* and their allies. *Paropsis* contains more species than any other Australian genus, some of which closely mimic Coccinellidae; others have in life exquisite colours, which fade rapidly after death, and thus become difficult to identify. The Halticinae (flea-beetles) contain genera mostly limited to Australia. The Hispinae are often closely set with spines. The Cassidinae are tortoise-like in form, fragile in structure and often of fugitive colours.

The group Rhynchophora has the head prolonged into a beak, with small, cutting mandibles at the apex; the tarsi are 4-jointed. Of this group by far the most important family—in number about one-fifth of the whole world of beetles—is that of the Curculionidae (weevils), of which more than 3000 species have been recorded from Australia, and many are notorious as vegetable pests and borers (see WOOD-BORERS). The Leptopsinae are apterous; many species of the typical genus *Leptops* attain great size, and are destructive to native and cultivated trees. *Catasarcus,* except for one species that ranges to Victoria, is confined to Western Australia. *Mandalotus* is a large genus of small species, often with remarkable sexual features. The Amycterinae—apterous ground-weevils with hard, rough cuticles—are confined to Australia, many of the smaller genera being limited to Western Australia. *Talaurinus,* and the allied *Sclerorrhinus* abound in the temperate and drier regions. The spiny *Acantholophus* and *Hyborrhynchus* are especially numerous in the west. The most striking genus is *Psalidura,* the males of which have a pair of powerful forceps protruding from a large apical excavation of the abdomen.

The Gonipterinae, almost confined to Australia, are peculiar in their covering of powdery meal. *Gonipterus* and *Oxyops* are abundant. In *Syarbis* the clawjoint is lost, the third joint being modified into a pad. Of the Hylobiinae, *Orthorrhinus* occurs in great numbers; *Eurhamphus fasciculatus* (found on pine-trees in Queensland and New South Wales) is the most striking species. The ornate Diamond-beetle (*Chrysolophus spectabilis*) belongs to this group. The Erirhininae include hundreds of small species; the clawless *Misophrice,* almost confined to casuarina trees, contains many species with brilliant scales. The Belinae are narrow, winged species limited to Australia, except for a few found in Papua, New Zealand, and South America. Of the timber-boring Cryptorhynchinae nearly 1000 species have been described; some of the genera range to Papua and New Zealand. *Protopalus* contains the largest species, with unusually long beak and antennae: in *Glochinorrhinus* there are tusk-like processes on the rostrum of the male. *Embaphiodes pyxidatus, Aethreus cicatricosus,* and *Hybomorphus mc'anosomus* are curious forms found on Lord Howe Island. Of the few Calandrinae, *Trigonotarsus* (confined to Australia) has but one species, *T. rugosus,* found in *Xanthorrhoea* stems. The Cossoninae are very numerous in Lord Howe and Norfolk Islands, which together produce more species than the whole mainland; (their chief Australian habitat is Queensland). Two blind species of *Halorhynchus* are found in Western and South Australia, and the Tasmanian *Tasmanica myrmecophila* is also blind. Of the allied families, the Scolytidae, with short rostrum, are few in number, but destructive to timber. The Brenthidae, of narrow elongate form and straight rostrum continuing the axis of the body, are few, and belong mostly to wide-ranging genera. *Cordus hospes* occurs in nests of

ants and termites in all the States. The Anthribidae, often with long antennae, number about 50 species on the mainland, but are numerous on Lord Howe and Norfolk Islands.

The very large group Lamellicornia—in whose members the terminal joints of the antennae form leaf- or comb-like plates, the feet have five tarsi, and there are in the males horn-like processes on head or pronotum—includes two families. The Lucanidae (stag-beetles) are remarkable for the enlarged mandibles of the males. They breed in decaying wood, and number 90 species in Australia. *Rhyssonotus* and *Lamprima* are peculiar to Australia, the latter containing fine species of brilliant metallic colours. *Phalacrognathus muelleri* (fig. 1), from northern Queensland, is one of the handsomest beetles in the world. *Eucarteria floralis* is a singular little species, found on flowers in the Dorrigo district of New South Wales. *Ceratognathus* and *Lissotes* are strongly represented in Tasmania, and extend to New Zealand. The Passalinae consist of large, black, parallel-sided species that abound in decaying logs in forest country; the external sexual features are little in evidence. Their species mostly belong to two genera, *Pharochilus* and *Aulacocyclus;* they stridulate loudly, and form a connecting link with the Scarabaeidae (chafers). These are more abundantly represented in Australia than in any other continent, by nearly 1600 species, contained in 160 genera and 8 subfamilies. The Coprinae and Aphodiinae are mostly dung-eaters, and through the paucity of large native animals are but scantily represented. The species of *Cephalodesmius* form balls of earth in which they place their larvae. The Geotrupinae, chiefly of the genus *Bolboceras*, bore two feet or more into the soil, stridulate loudly, and are readily attracted to light. The Troginae occur mostly in dried carrion. The Melolonthinae, comprising more than half the family, occur on flowers and foliage. *Heteronyx* alone contains 400 species of dingy colours; *Haplonycha, Pachytricha,* and *Lepidiota* include the bulkier forms. The metallic species of *Diphucephala* sometimes cause foliage to seem bespangled with gems. The Rutelinae also occur in masses, denuding eucalypts of their leaves; among them *Anoplognathus* and its allies are prominent, *A. viridiaeneus* being the well-known 'King'-beetle of the Sydney district. The Dynastinae are mostly solid, polished black species, whose males have conspicuous horns. *Haploscapanes barbarossa* is the largest of Australian beetles; *Cryptodus, Cavonus,* and *Pseudoryctes* all contain interesting forms. The Cetoninae are especially valued by collectors for their beauty of pattern: they have strong powers of flight, and are usually taken on flowers. *Diaphonia* and *Chlorobapta* are widely distributed. *Lomaptera* and *Trichaulax* (fig. 2), are typical of the fine tropical genera. A single species of *Microvalgus* is the only Tasmanian representative of the sub-family.

For the systematic literature up to 1887 see Masters's *Catalogue of the Australian Coleoptera,* published by the Linnean Society of New South Wales. Amongst Australian entomologists the pioneer work of W. S. Macleay (see MACLEAY, ALEXANDER) has been followed up by Blackburn, Carter, Ferguson, Lea, Olliff, and Sloane, whose work may be found in the publications of various Australian learned societies. See also Tillyard's *Insects of Australia and New Zealand.* H.J.C.

ECONOMIC IMPORTANCE. Many beetle families —notably the chafers, scarabs, weevils, borers, and longicorns—are pests of great economic importance. The Sugar-cane Beetle (*Lepidiota albohirtum*), a large chafer densely clothed with white scales, infests the Queensland canefields, its larvae attacking the roots of the canes in large numbers. Tons of beetles and grubs are destroyed yearly, but these probably include many harmless species. The beetle's life-history is known, but root-pests are difficult to combat, and no satisfactory remedy has yet been found. *L. frenchi* also attacks sugar-cane, but to a slighter extent.

A small bright-green scarab (*Diphucephala colaspidoides*) is a serious pest to stone and pip fruits, and to raspberries, in Victoria and Tasmania. It occurs in numbers sufficient to bend and completely to defoliate branches, and is especially prevalent where wattle-trees have been numerous. When an apple-tree is attacked, every leaf is sometimes riddled, though only one out of a bunch of apples may be infested; on that apple, however, so many beetles will be crowded that room can be found only for their heads and front-legs. The larvae destroy grass-roots. A small brown chafer (*Scitala pruinosa*) similarly defoliates pear, cherry, and plum trees. When flying round a tree at night, its numbers produce a sound like that of swarming bees. Several species of *Heteronyx* similarly injure fruit and other trees at night.

The large, brilliantly metallic chafers (*Anoplognathus* and its allies) commonly known as king-beetles attack the foliage of eucalypts, pepper, and other trees; their larvae as a rule feed on rotting wood or grass-roots and, in some species, on strawberry plants. In Western Australia the allied *Anoplostethus opalinus* injures pear trees; in Queensland *Calloödes grayanus* attacks sugar-cane.

Among the weevils *Leptops squalidus* in Victoria and New South Wales, *L. robustus* and *L. rhizophagus* in South Australia, unsatisfied by their natural hosts the wattles, have become serious menaces to apple trees, and sometimes to grape-vines; the larvae gouge out channels along the main roots, and open the way for fungous growth. *Orthorrhinus cylindrirostris* attacks citrus, stone, and pip fruit with indiscriminate appetite, the beetles nibbling the buds and bark, the larvae boring the stems. They are especially prevalent near newly-cleared land or ring-barked country, and a newly-felled eucalypt may at night swarm with them. Two smaller species, *O. klugi* and *O. aethiops,* are destructive, the former to the rose in particular.

Strawberries are so injured by two species of weevils—*Rhadinosomus lacordairei* and *Rhinaria perdix*—that many Tasmanian growers have ceased to cultivate this fruit on a commercial scale. In South Australia *Neomerimnetes destructor* has been found to riddle the foliage. *Desiantha maculata, D. nociva,* and *Perperus malevolens* may be termed 'bud-weevils,' the first attacking the buds of fruit-trees and grape-vines by night, the second specializing in tomatoes and other vegetables, the third preferring apricots and other fruit-trees. In New South Wales and Queensland a tiny weevil known as 'Dicky Rice' (*Maleuterpes phytolymus*) attacks the leaves of citrus trees, so that they appear as if threshed by hail.

Shot-hole borers (Scolytidae) and auger beetles (Bostrychidae) attack trees and newly sawn timber. Of the latter family *Bostrychopsis jesuita* riddles orange trees over a wide range, *Xylion collaris* has been found attacking stored wheat, and *X. cylindricus* occurs in mills as well as in timber; *Xylothrips gibbicollis* has been recorded as boring into lead—as also have certain species of white ants. Introduced beetles be-

longing to the same tribe (Bostrychoidea), close relatives also of the European 'death-watch,' are described under WOOD-BORERS, as are the shot-hole borers which affect unseasoned wood.

Three introduced weevils of interest to horticulturists are *Neosyagrius cordipennis*, which breeds in maiden-hair fern, *Syagrius fulvitarsis*, which infests the frond-stems of larger ferns, and *Acythopeus aterrimus*, found in the pseudobulbs of orchids.

In eastern Australia citrus fruits may be attacked by a fine longicorn beetle, *Uracanthus cryptophagus*, whose larva drills a branch and constructs a special chamber above which it pupates. With the first heavy wind the branch snaps at this chamber. The allied species *U. maleficus* similarly destroys filberts in Tasmania. Many other longicorns attack eucalypts and wattles: thus the well-known 'firewood beetles' (*Phoracantha* and its allies) may be seen in quantities at night on felled timber; and they have lately been introduced into South Africa, where they are a serious pest on wattle plantations.

The Pumpkin Beetle (*Aulacophora hilaris*) attacks all the cucumber family, and is widely distributed in Australia, sometimes rendering pumpkin-growing almost impossible. Another leaf-eater in eastern Australia is *Monolepta rosea*, and *M. divisa* attacks grape-vines.

Among introduced grain-beetles the Wheat Weevil (*Calandra oryzae*) gained notoriety by his devastating attacks on immense stacks awaiting export during the war; over 8 millions of bushels were lost through this pest and *Rhizopertha dominica*. The former attacks maize, and may often be seen in the ripening cobs. Other mischievous pests in flour or grain are *Calandra granaria*, *Tribolium ferrugineum*, the horned *Gnathocerus*, *Tenebrio molitor*, and *T. obscurus*, *Anobium paniceum* (Biscuit Beetle) and the saw-toothed *Silvanus surinamensis*. The smaller kinds may often be seen baked in bread. It is now known that grain-weevils can develop only where the environment is sufficiently moist; protection can thus be secured by giving wheat perfectly dry storage, as in properly constructed elevators. (See WHEAT.)

Three European weevils of the large genus *Otiorhynchus* have become established in Australia. Of these the small brown *O. cribricollis* does an immense amount of damage to fruit-trees and other cultivated plants, including the rose, and in some districts is more injurious to apple trees than all other pests combined; leaves, bark and fruit are all attacked, and the roots are injured by the larvae. The larger *O. sulcatus* is troublesome in Victoria and Tasmania, but the third, *O. scabrosus*, has not yet become a serious danger.

In Queensland and New South Wales the Sweet-potato Weevil (*Cylas formicarius*) has been introduced.

The Cigar Beetle (*Lasioderma serricorne*) attacks tobacco, stored meals and other dried products; strychnine beans in a chemist's shop in Adelaide were reduced to powder by these beetles, which also injure dried plants and certain kinds of leather.

The skin-eating *Dermestes* are cosmopolitan and ubiquitous. *D. vulpinus* and *D. cadaverinus* are to be seen on carrion throughout the country, and green hides are painted with arsenical preparations as a protection against them. *D. lardarius* is a bacon pest, found in most stores, and the allied species of *Anthrenus* are notoriously destructive to natural history specimens in museums.

A.M.L.

Bell, SIR JOSHUA PETER (1827-1881), born in county Kildare, Ireland, on 19 January 1827, was brought by his parents to Sydney in 1831 and educated at Sydney College and the King's School. In 1847 the family acquired from Richard Scougall Jimbour station, one of the biggest and best estates on the Darling Downs, and Joshua soon became known as a grower of prize wool. Elected to the Queensland legislature in 1863, he joined the Herbert ministry as treasurer in 1864 and retained the post under Macalister. During 1866, being faced with the failure of two banks and a consequent financial crisis, he proposed to issue inconvertible 'legal tender' notes to the amount of £200,000, but Sir George Bowen, then governor, refused to countenance such a policy, and the ministry resigned. Bell retained his seat in the assembly until 1879, holding office under Macalister (1866-7) as secretary for lands and under Palmer (1871-4) as treasurer. In 1879 he was transferred to the legislative council and made president of that body—in which capacity he administered the government from March to November 1880 during the absence of the governor. He died on 20 December 1881. (K.C.M.G., 1881.)

—His son JOSHUA THOMAS BELL (1863-1911), born on 1 March 1863 and educated at Ipswich and Brisbane grammar schools and Trinity Hall, Cambridge, was called to the bar at the Inner Temple in 1888, and in 1890 became private secretary to Samuel Griffith. In 1893 he entered the assembly as member for Dalby (the constituency in which Jimbour lay), and after an active career as a private member—during part of which he was chairman of committees—joined Arthur Morgan as secretary for lands (1903-6), retained that office in the first Kidston ministry (1906-7), and resumed it for eight months in the second Kidston ministry, but was then ousted by D. F. Denham. For another eight months he remained in the ministry as home secretary, but on 29 June 1909 retired from active politics, a disappointed man, to the speaker's chair. In July 1910 ill-health forced him to hand over his duties to a deputy, and on 10 March 1911 he died. Bell was one of the ablest men in the parliaments of his day, but his polished manners and scholarly reputation cut him off from the mass of his fellow-members and detracted from his popularity. He was specially interested in land legislation. While still a private member he passed the first of a long series of acts designed to encourage the extirpation of the prickly pear pest. His land acts amendment act of 1905 was drafted 'with the object of putting as many people on the land in Queensland as official action can accomplish,' and might have accomplished a great deal but for the unsympathetic administration of his successors. Among many notable features it provided for the provisional selection and purchase of farms by intending settlers before they left England—the option being left to them of cancelling the purchase after a fair trial of the chosen farm—and for the settlement of groups of migrants (either from Britain or from other Australian States) on adjoining farms.

Belmore, EARL OF (1835-1913). Somerset Richard Lowry-Corry, born in London on 9 April 1835, was the eldest son of the third earl of Belmore and succeeded his father in December 1845. He was educated at Eton and Cambridge (M.A., 1856). Elected a representative peer for Ireland in 1857, he was for the next ten years employed on committee work of the house of lords, and in 1866 became a junior member of the third Derby ministry. The next year he was appointed governor of New South Wales, and arrived in Sydney on 7 January 1868, in time to receive Prince Alfred (the Duke of Edinburgh), who as captain of H.M.S. *Galatea* was on a visit to the Australian colonies. On 12 March, while at a public gathering in Clontarf gardens, Middle Harbour, Prince Alfred was shot in the back by a Fenian, Farrell, but not seriously hurt. This, and the opening of the first intercolonial exhibition in Prince Alfred park during 1871, were the only important events of Lord Belmore's governorship. His health compelled him to resign his post on 22 February 1872; he returned to England, and spent the rest of his life in minor public duties and in managing his Irish estates. As his wife was a niece of W. E. Gladstone and his cousin (Montagu Corry, afterwards Lord Rowton) private secretary to Lord Beaconsfield, he was a *persona grata* in both political camps. He served on two educational commissions and on the judicial committee of the Irish privy council. He died on 6 April 1913. (K.C.M.G., 1872; G.C.M.G., 1890.)

Benedictine Order, THE, IN AUSTRALIA. While the foundations of the Catholic Church in Australia were surely laid by a secular priest—Father Joseph Therry, q.v.—the credit of building it on those foundations for its first half-century belongs to a succession of Benedictine fathers and bishops. Even before Father Therry's arrival the settlements in Australia had been placed under the jurisdiction of a Benedictine, Bishop Slater of the Mauritius, who was succeeded in that see by another Benedictine, Bishop Morris. The first priest of the Order who actually worked in Australia was Father Ullathorne; he was soon followed by Dr. Polding, first bishop and archbishop of Sydney, who brought with him or in his train a long series of Benedictines, most of them from the monastery of Downside in Somerset. The most notable among these, after Drs. Polding and Ullathorne, are perhaps Archbishop Vaughan of Sydney, Bishop Davis of Maitland, Abbot Gregory of the monastery founded at Sydney, and (from the Spanish Benedictines) Abbot Salvado of New Norcia in Western Australia, whose work is still under Benedictine control. A short account of the New Norcia settlement is given under that name.

In 1847 Archbishop Polding brought out from English convents two Benedictine nuns to establish in New South Wales a convent and a girls' school. He settled them on an estate then known as 'The Vineyard' (now Subiaco) near Parramatta, which he bought from Hannibal Macarthur; the convent was opened on 2 February 1849 and the school on 25 March 1851. The school is now closed, and the convent has adopted the strict Benedictine 'enclosure.' In 1925 30 members of the community were securely maintaining the foundation. Details are given in H. N. Birt's *Benedictine Pioneers in Australia* (ii. 399-404), which should also be consulted on the whole subject. E.M.O'B.

Bennett, GEORGE (1804-1893), born at Plymouth in England on 31 January 1804, took to sea travel at an early age, and when only 15 visited Ceylon, returning in 1821 by way of the Mauritius. He then studied medicine (M.R.C.S., 1828; F.R.C.S., 1834; M.D., Glasgow, 1859), and as soon as he had obtained his first diploma joined the *Sophia*, which in November 1828 began a voyage of exploration in the Pacific. In this vessel, where he had charge of the scientific observations, he in 1829 visited Sydney. Returning to England in 1831, he left the next year in the *Brothers*, landed at Sydney on 25 August, and spent seven months in the western foothills of the main range from the Cudgegong southwards, devoting especial attention to the Tumut and upper Murrumbidgee districts; the results of his observations in Australia and during a very roundabout return to England he embodied in a book—*Wanderings of a Naturalist in New South Wales, Batavia, Pedir Coast, Singapore and China*—published in London in 1843. His most important observations, however, those on the platypus (which he was the first to describe with any detail), were entirely omitted from this book and published separately the same year as *Notes on the Natural History and Habits of the Ornithorhynchus Paradoxus*. During 1835 he was back in Sydney, where he settled down to practise his profession, but was never too engrossed in it to neglect the study of natural history. For 50 years he kept up a regular correspondence with Sir Richard Owen—whose first great scientific memoir 'On the Pearly Nautilus' was based on a specimen, the first ever preserved of the actual animal (as distinguished from its shell), which Bennett had obtained in the New Hebrides in 1829 and brought to England for him in the *Sophia*. In Sydney he took an active interest in the botanic gardens, the Zoological and Linnean Societies, and the Australian Museum, of which he was the first curator. His title in this office varied from time to time; prior to 1841 he was called director, superintendent, zoologist, curator or secretary in various equally official documents. In 1838-53 he was also a member of the museum committee, and in 1853-74 an elected trustee of the institution. Among his discoveries must be noted that of the New Britain cassowary (named in his honour *Casuarius Bennetti*). In 1877-9 he visited Europe, and received scientific honours in both England and Italy. He died at Sydney on 29 September 1893.

Besides the books already mentioned he was the author of *Gatherings of a Naturalist in Australasia* (1860), and of pamphlets or reports on influenza in sheep (1836), acclimatization (1862) and the cultivation of citrus fruits (1871). Among his many honours he received the gold medal of the Royal College of Surgeons, the silver medals of the Zoological Society of London and the Acclimatization Society of Victoria, and the Clarke memorial medal of the Royal Society of New South Wales.

Bennett, SAMUEL (1815-1878), born at Camborne in Cornwall on 20 March 1815, came to Australia in 1841 under engagement to the then proprietors of the *Sydney Herald* (now *Sydney Morning Herald*), Messrs. Stephens and Stokes, and when Messrs. Kemp and Fairfax took the newspaper over became head of the printing department, a position which he occupied for 17 years. In 1859 he bought the *Empire*, which

Henry Parkes had started in 1850, and ran it as a daily newspaper with a weekly edition until 1875. In 1867 he commenced publication of the *Evening News*, to which three years later he added a weekly paper, the *Town and Country Journal;* and in 1875 he amalgamated the *News* and the *Empire*. He contributed often to the literary columns of his papers, and in 1865 began to compile a *History of Australian Discovery and Colonization* which appeared in chapters in the weekly edition of the *Empire*. In 1867, however, when the narrative had reached the year 1831, he found business affairs too pressing to allow of further historical research, and accordingly published what had already been written as a book (five parts in one volume); this was for many years the best and most accurate account of early Australian history, and is still worth study. It may be noted that many copies have a double title-page, that dated 1865 being the original title-page of the first part, and that dated 1867 the title-page proper to the whole book.

Bennett died at Little Coogee, near Sydney, on 2 June 1878. Henry Kendall, with whom he had a warm friendship, enshrined his name with those of Stenhouse, Harpur, and William Ridley in 'By the Cliffs of the Sea.'

Bent, Andrew (1795-1850), is first heard of as an employee on the government printing press in Hobart soon after 1810. Fawkner's *Launceston Advertiser* on 3 August 1829 printed a statement in which Bent—described as 'the "errand boy" from the *Public Ledger* office in Warwick Square, London'—is said to have been taken on as assistant by George Clark (the printer of the first Tasmanian newspaper) 'in process of time'—that is, not actually at the beginning of the publication. However, since the same authority states that Bent 'came to the colony a mere boy, and has resided in it sixteen or seventeen years,' he could hardly have been in Clark's employ before 1812, by which time the newspaper had been discontinued. In 1814 a second attempt was made, the *Van Diemen's Land Gazette* appearing in nine issues between May and September with Clark as printer; soon afterwards Clark was dismissed by the government, and on 1 June 1816 Bent issued 'by Authority' the first number of the *Hobart Town Gazette*. At the same time he carried on business as general printer, in 1819 issued the first Tasmanian book (a biography of Michael Howe the bushranger), and in 1821 added copper-plate printing to his business. In 1825 he was involved in trouble with Governor Arthur, having published a series of letters signed 'Colonist' which attacked the administration with much acridity, and on 1 August was fined £500 and imprisoned. The *Gazette* passed into other hands, but Bent took the earliest opportunity of issuing the *Colonial Times*, which, he claimed, 'was established in 1816 under the title of the *Hobart Town Gazette.*' As might be expected, the *Times* devoted itself to attacks on the government; after about two years he handed it and its traditions on to Henry Melville, chiefly because Arthur had on 19 October 1827 prohibited the publication of unlicensed newspapers and simultaneously refused to grant Bent a licence. Bent tried to continue the *Times* as a sheet of advertisements, issuing also a monthly magazine, the *Colonial Advocate* (March-October 1828); Arthur had him condemned and imprisoned for the first publication, and released him only on a promise to drop the second. Since the licensing act was disapproved by the British government, Bent appears to have deserved compensation; but he got none. His printing office continued to do business, and from it in 1824 was published the first *Van Diemen's Land Almanack*, which Bent himself compiled. But he could not abandon journalism; in 1833 he was publishing Robertson's paper, *The True Colonist;* in 1835 he started another venture of his own, *Bent's News and Tasmanian Threepenny Register*, which ran till the middle of 1837; then, tired of the long struggle, he migrated to Sydney, taking his printing plant with him, and issued the first number of *Bent's News and New South Wales Advertiser*, which ran for two years and was then sold to the Roman Catholics to reappear as the *Australian Chronicle*. In 1843, by which time he had left Sydney and settled on the Macleay River, he was out of work and appealing for a position as printer, reader, or superintendent of some public journal, claiming to be 'the Father of the Press in these Colonies.' In 1845 he was forced into an appeal to 'the generous inhabitants of Van Diemen's Land,' and in 1850 died in straitened circumstances.

Bent, Ellis (1779-1815), son of R. Bent, was educated at Cambridge and called to the bar in 1805, practising on the northern circuit. Four years later he was sufficiently well-known to be described by Lord Castlereagh as 'a barrister of eminence.' In 1809 he was appointed—apparently on the recommendation of General Nightingall—judge-advocate of New South Wales, the commission being ante-dated to 1 January. He made the voyage out with Macquarie, who was at once attracted by him, consulted him on all important legal matters for several years, and named Bent-street in Sydney after him. Up to Bent's time no judge-advocate had been a legal expert, and his chief work after his arrival was to devise a new system of courts and procedure to supplant the rough and ready proceedings of the early naval governors; his report of 19 October 1811 was adopted in its entirety by the parliamentary committee of 1812 on transportation, but its most important recommendation—for the establishment of trial by jury—was set aside by Lord Bathurst, who determined to retain the existing system of criminal trials while establishing two new courts on the civil side. Macquarie promptly recommended Ellis Bent for the principal judgeship, and suggested his younger brother Jeffery Hart Bent as assistant judge. In the end, however, J. H. Bent was made sole judge.

The two brothers were of very different temperaments. Ellis was in 1811 described by Macquarie as 'blending the mildest and gentlest disposition with the most conciliating manners, great good sense, and accurate legal knowledge;' and all else we know of him confirms this judgment. Jeffery, on the other hand, was exceptionally hot-tempered and sensitive of slights, and often unrestrained in his language. It would not have been surprising if his arrival in the colony had led to friction between Macquarie and Ellis Bent. But in fact the friction had already occurred. In the spring of 1813, according to Macquarie, Bent grew impatient at the delay in building him a proper court-house, and an angry conversation resulted in the abandonment on both sides of all friendly intercourse; while the facts may be as Macquarie states, it is more probable that the personal element in the quarrel was due mainly to Macquarie's persistent policy of introducing emancipists at government house as the

social equals of the free settlers and officials, against which Ellis Bent protested in a letter written to Lord Bathurst in October 1814. Undoubtedly the existing friction was considerably embittered when Jeffery Bent arrived. The brothers were at one in determination not to admit to practice any ex-convict attorney, and Ellis, besides several minor grievances, was at odds with Macquarie about a matter curiously like that which nine years later caused a bitter dispute between Saxe Bannister (q.v.) and Brisbane. Macquarie drafted some port regulations and sent them to Ellis Bent (his official legal adviser) for revision and proper phrasing: Bent refused on the grounds (*a*) that it was not his business, (*b*) that he thought some of them *ultra vires*: both sides appealed to the authorities in London, and Bathurst decided that Macquarie was right, and that the Bents must be removed from office. It is important to note the ground of this decision. In their protests, said Bathurst, the Bents were right: convict attorneys should not be employed except in very rare circumstances, and Ellis Bent was justified in protesting against the port regulations if he thought them *ultra vires*. But neither he nor his brother had any right to embarrass the administration of the colony because of differences of opinion, and Macquarie's forbearance in not suspending them from office, and so holding up judicial proceedings in the colony, was specially and warmly approved.

Before, however, this recall could be put into force—before it was even decided on—Ellis Bent was dead. A long illness (which may have helped to make him unwontedly impatient in the last year of his life) ended on 10 November 1815, just after he had been given long leave to take a holiday in India and Europe. And Macquarie's despatch of 16 January 1816, recording the death, and witnessing to Bent's faithful, indefatigable, and able administration of justice during the whole of his public career, is good evidence of the writer's as well as of the subject's virtues.

Bent was buried in the George-street cemetery (where the town hall now stands); but his body was soon removed to Garden Island, where after a while he shared a grave with Major Ovens. Then both bodies were transferred to the graveyard of St. Thomas's, North Sydney, where they now rest under the Garden Island monument. Bent's first gravestone was simply turned over and used later for that of Anthony Fenn Kemp.

Bent, Jeffery Hart (1780-1852), brother of Ellis Bent mentioned above, was like him educated at Cambridge, and seems to have been called to the bar in 1806. In 1814 he was appointed by the colonial office first judge of the newly created supreme court, and reached Sydney on 28 July in that year. But the court never functioned under him. On various pretexts he delayed the first sitting until 1 June 1815, and then the first business concerned the admission to practice of certain local attorneys who had been sent out as convicts. They had since become free men either by expiration of sentence or by formal emancipation, and had been allowed to practise in the old court; but Bent announced that no persons who had been transported to Australia would ever be allowed to practise before him, and persuaded his brother to make a similar rule for the 'governor's court' over which he presided. It so happened that the first two applicants for admission had been originally convicted, the one of perjury, the other of forgery, so that there was obviously a prima facie case against their admission as officers of a court of justice; and the two magistrates who sat on the bench with Bent, while disagreeing with his general rule, explicitly reserved the right to refuse their applications. But Bent's hasty and domineering disqualification of all emancipists, his behaviour in court and outside to the magistrates and others who questioned his decision, and his suspension of all the functions of the court until a final decision could be received from London, roused against him not only public feeling in the colony and the wrath of Macquarie but also the severe displeasure of Earl Bathurst. 'Whether convicts be or be not authorized to practise' wrote Bathurst, 'is a question of little importance when compared with the consequences arising out of its agitation, the closing of the supreme court of the colony for at least twelve months.' Bent was accordingly recalled. By this time, however, he seems to have lost his head altogether, for he had committed to gaol one of his own colleagues who was employing Mrs. Bent's ex-cook, had repeatedly forced his way through toll-gates without paying toll, and even after his formal suspension by Bathurst claimed that he must retain his position until the arrival of his successor. Consequently Macquarie on 11 December 1816 announced in general orders that Bent was 'positively and absolutely removed' from the judgeship, and early in 1817 he returned to England by way of India. For two years thereafter he persistently bombarded the government with demands for reparation in one form or another—he even suggested that he should be appointed 'Civil Governor of New South Wales.' In 1820 he was made chief justice of Grenada, passing on to a similar position in St. Lucia, thence to the bench of Trinidad and finally to the chief justiceship of British Guiana. He died in office on 29 June 1852.

Jeffery Bent was first and foremost gifted with immense self-conceit. At the back of every complaint he made and every trouble he stirred up we detect irritation at something which he took for a personal insult. 'My Office as Judge of the Supreme Court and as a Barrister of near 10 years standing' was in his eyes the central fact of the situation in all correspondence with Macquarie and with his colleagues. In a convict colony under military rule, with its free institutions still in a state of flux, this insistence on details of etiquette and claim to authority independent of the governor's was not only embarrassing but dangerous, and Bathurst could do no less than remove him: but the same temperament might be (and apparently was) harmless and even useful in older colonies, where the minutiae of procedure regarding interdependence, relative rank, etc., had long since been laid down and stereotyped.

Bent, Sir Thomas (1838-1909), born on Sir John Jamison's estate near Penrith in New South Wales on 7 December 1838, and brought while a child by his parents to live on a market-garden in the closely cultivated area south-east of Melbourne, in 1859 started a garden of his own and began to interest himself in municipal life; in 1861 he was made rate-collector for Brighton, and the next year entered the Moorabbin shire council. Thoroughly representative of the community he lived in, and gaining much popularity among his neighbours, he surprised Victoria in 1871 by defeating George Higinbotham, the ablest man then in public life, for the Brighton electorate; Higinbotham knew little about the

local needs of his constituents and fought the election on big issues, whilst Bent spoke as a market-gardener to others of his trade. Moreover, Higinbotham's sturdy Australianism and his opposition to the interference of the colonial office in local affairs arrayed against him most of the wealthy voters of what was then an aristocratic community. Bent, on the other hand, was already a trusted organizer in the conservative party, and a man of capacity, courage and self-reliance. Entirely self-educated and a keen student of his fellows, he soon became 'an old parliamentary hand,' attached himself to the party led by Service (q.v.), was made party whip, and was mainly responsible for Berry's defeat in 1880. In the short-lived Service ministry of that year he held a small unsalaried position, but in the O'Loghlen ministry of 1881-3 was minister of railways, and was so lavish in his expenditure and his proposals for new non-paying, vote-catching lines that his administration was Service's chief argument a year or two later for the handing over of the railways to a non-political commission. These lines, it may be added, are among the best railway assets of the present time. Towards the end of 1883 he was acting-leader of the opposition, but was found too brusque for the work. In 1887 he was made chairman of the parliamentary standing committee on railway construction, and surpassed his previous record of expenditure, but in May 1892, in anticipation of a regime of railway economy, was transferred to the speakership of the house of assembly. While occupying this post, he never troubled to become a master of parliamentary practice, substituting a ready mother-wit for this knowledge. On one occasion, in a sudden turmoil, he gave a ruling that was obviously against all precedents, and when challenged said nonchalantly 'Well, that's my ruling for to-night anyway.'

Having from 1887 onwards taken an active (but not a dishonourable) part in the land 'boom' which ended disastrously in 1893, Bent was left almost penniless, was rejected by the Brighton electors and spent the next six years farming near Port Fairy. It was from the experience of these years that he learnt, as he afterwards said, 'to take off my hat to a cow.' In 1900 he re-entered State politics, was once more elected for Brighton, engineered his way to the front, and in June 1902 joined W. H. Irvine's ministry as commissioner of public works and minister of railways. Irvine being rather a philosopher than a politician, Bent was the mainstay of this ministry, and the defeat of the great railway strike of 1903 was mainly his work. In February 1904 Irvine, weary of dealing with men whose thoughts and motives he could not understand, resigned office and left the premiership to Bent; this he held until December 1908, when he was defeated in parliament. He died worn out on 17 September 1909.

Thomas Bent was a sturdy political fighter, of great natural capacity and shrewdness, and a keen student of finance. He was quick to discern incapacity or mediocrity in his subordinates, and attached to himself, particularly in the treasury, men on whom he could rely. He understood, too, the necessity of increased assistance to university and secondary education, and on the report of a royal commission doubled the endowment of the university of Melbourne, and made available a large sum to cover all its outstanding needs. His career is at once an advertisement for and a warning against ultra-democracy. He won and retained many unsuitable positions simply by being just on a level with the men who chose him; if he had little expert knowledge and low standards, so had they; they liked his 'masterfulness,' and said approvingly that he 'had no nonsense about him.' It is much to his credit that on certain matters, such as education, he admitted his ignorance and sought the advice of the best men procurable. Further, while using any convenient means to gain his ends, he never shirked the responsibility for having used them —an unusual virtue among politicians. (K.C.M.G., 1908.)

Berry, ALEXANDER (1781-1873), born at Cupar in Scotland on 30 November 1781, was educated at the Cupar grammar school (where he had for a fellow-student John Campbell the great lord chancellor) and at the universities of St. Andrews and Edinburgh. At the latter he qualified as a surgeon, and almost immediately joined the service of the East India Company as surgeon's mate, rising after one trip to China to the position of surgeon in the *Hawkesbury*, and combining his professional duties with a certain amount of trading. A few years later he shipped as supercargo in a vessel trading to the Cape of Good Hope, and while there heard that great floods had caused a famine in New South Wales. At once he bought a 526-ton prize ship lying in Table Bay, named her the *City of Edinburgh*, took aboard a cargo of provisions, and sailed for Australia on 4 September 1807. Persistently stormy weather forced him to put into Port Dalrymple in Tasmania, where his cargo was very welcome; half he sold there, and took the rest to Hobart, where also provisions were much needed. When on 12 January 1808 he reached Sydney, he found himself in hot water with Bligh for not bringing the cargo to Sydney first; as within a fortnight Bligh had been arrested and deposed by the New South Wales Corps mutineers, this did Berry little harm. A month or two later Colonel Johnston chartered the vessel to fetch settlers from Norfolk Island to Hobart in order to complete the evacuation of the island; the freight was to be paid in timber, but the excessive length of the voyage (owing to bad weather the round trip took 24 weeks) so increased the charge for freight that the acting-governor refused to pay it. Berry, whose sole desire at the time was to get back to the Cape with a profitable cargo, had to wait about in Port Jackson, and at last sailed for Fiji to load sandalwood. On his way he touched at the Bay of Islands in New Zealand, to get spars for his vessel, going on via Tonga to Fiji (where he was for a time a prisoner), and then returning to New Zealand; there he heard that a big English vessel had been captured and looted at Whangaroa, and was able to rescue the four survivors of the transport *Boyd* (for the full story see NEW ZEALAND). Then, loading up with spars for naval use at the Cape, he started eastwards on 26 January 1810. Storms almost shattered the vessel off Tierra del Fuego, and in despair Berry made along the Chilean coast to Valparaiso and Callao, where he procured a fresh cargo and started for Cadiz. This time he rounded the Horn safely, and visited Rio on the way; but near the Azores the vessel was found to be leaking beyond repair and had to be abandoned. Making his way first to the Azores, then to Lisbon, and thence to Cadiz, he witnessed Soult's bombard-

ment of that city in 1812, caught the yellow fever there, made a lifelong friend of Edward Wollstonecraft (afterwards his partner and brother-in-law), and on his way thence to England was captured by a Yankee privateer.

Such an adventurous youth could hardly be expected to lapse into sober English commercialism. In 1819 Berry and Wollstonecraft decided to settle in Australia. Chartering a vessel, Berry took out a cargo and did so well with it that Macquarie early in 1820 described him as 'an eminent merchant . . . . well acquainted with the present state and resources of this colony.' Wollstonecraft (who had come out independently) stayed on in Sydney and secured from Macquarie a 500-acre grant on North Shore which he named 'Crow's Nest;' Berry returned to England, chartered another vessel, and in it brought out Governor Brisbane and his staff. The Crow's Nest grant was all very well for the residence of a Sydney merchant, but did not suit Berry's pioneer temperament; he therefore left his partner to look after the commercial side of the partnership in Sydney (where Wollstonecraft became senior director of the Bank of New South Wales and a prominent member of the chamber of commerce), and obtained from Brisbane a 10,000-acre grant in the Shoalhaven district, where he settled under Coolangatta Hill. The district was at that time practically inaccessible overland, and quite unapproachable by the mouth of the Shoalhaven River, so that Berry had to cut a canal from the river to a little haven south of it (known as Crookhaven) before any real settlement could be begun. Access once given, however, the Shoalhaven district became very popular, and in 1826 Berry and Wollstonecraft were forced to give public notice 'that they have not opened a Public Tavern at Shoalhaven.'

That was the end of Berry's adventures. For the rest of his life—nearly 50 years—he devoted himself to developing the Shoalhaven estates, which he enlarged to 80 square miles by purchase, and to the management of the Sydney business after Wollstonecraft's death in 1832. As this necessitated continued absences from the estate, in 1836 he fetched from Scotland his brothers David and John to take over the control of the Shoalhaven property. He himself had been appointed to the legislative council in January 1829, held the post till 1843, when he was nominated to the new council, and when that was dissolved in 1856 became a member of the first legislative council under responsible government. When in 1861 the majority of members of that council resigned, Berry, who was one of them, retired into private life, and gave all the more attention to his estates; it is mainly his work that the Shoalhaven district—which Oxley had reported on as useless owing to its swampy nature—was developed to its present state of prosperity. He died at Crow's Nest on 17 September 1873.

Berry, Sir Graham (1822-1904), born at Twickenham near London on 28 August 1822, educated at Chelsea and apprenticed to a Chelsea draper, about 1848 opened a small shop in the King's Road; but the prospects of better business at the Victorian goldfields induced him in 1852 to migrate to Melbourne. He did not, however, pass through to the diggings, but opened a greengrocer's shop (which afterwards expanded into a general store and wine-shop) near the intersection of Chapel-street and Toorak-road. In 1860 he purchased the *Collingwood Observer*, entered politics, and was elected by chance for East Melbourne, but at the general elections of 1861 stood for Collingwood as an advanced protectionist and held the seat until 1865. During the angry debates on 'tacking' provoked by McCulloch (q.v.) Berry opposed all unconstitutional measures, and was ejected from Collingwood and rejected for the Murray Boroughs by McCulloch's excited followers. In 1866, therefore, he left Melbourne for Geelong, bought and amalgamated the Geelong *Register* and *Advertiser*, edited the new paper, and in 1868 was returned for Geelong West. In 1870 he joined the short-lived Macpherson ministry as treasurer, but his budget failed to balance, and the ministry went out; McCulloch, who was the next premier, proposed a property tax, and Berry attacked him on behalf of the manufacturers, while Duffy (q.v.) espoused the cause of the agriculturists; the joint attack was successful, and on 19 June 1871 Berry joined Duffy's ministry as treasurer and minister for customs. This meant the triumph of protection, and Berry might have held the ministry together and dominated parliament for some years, had not his appointment of his father-in-law to a minor office raised an outcry against him personally that drove him out of the government in May 1872.

For the next few years education, not the tariff, was the problem of current politics, and Berry was in obscurity. But in 1874 James Service became treasurer of the Kerferd ministry, and in the session of 1875 attempted to lower several duties. Berry at once came to the fore, drove the ministry from office, and himself took the premiership in a hostile parliament, though McCulloch and Kerferd, combining forces, ousted him after two months' tenure and as a coalition saw the parliament through its term. Berry stumped the country against them, and did his best to 'stonewall' business inside the legislature, and the elections of 1877 showed that the country was behind him. He was returned with a large majority at his back (60 to 26), and at once introduced or promised a number of highly controversial measures—particularly a land tax intended to break up large estates, a permanent provision for the payment of members (which had hitherto been effected by a series of temporary acts), and a drastic 'reform' of the legislative council. The land tax was carried in the council, but the bill for payment of members was blocked, and attempts to 'tack' it to the appropriation bill also failed. The situation now resembled that produced by McCulloch over an early tariff; but Berry, who had quarrelled with McCulloch over his unconstitutional methods of evading that crisis, could not now follow his example. Instead of allowing creditors of the government to sue for their money, he cut the knot by wholesale dismissals (see Black Wednesday) of county court judges, police magistrates, goldfields wardens, permanent heads of important departments, and officials of like calibre. This action brought about a compromise by which the obnoxious 'tack' was abandoned, but payment of members was authorized for the term of the parliament, and most of the dismissed officials were reinstated. Berry's next move was an attempt to extend the franchise of council electors and diminish the council's powers; that body, of course, rejected his bill, and he then proceeded, accompanied by Charles Pearson (q.v.), to England as an 'embassy' from the majority of Victorian electors

to ask the British parliament to alter the colony's constitution. His mission was a failure from the outset. His best supporter, Sir George Bowen (who as governor had approved and aided most of his drastic actions), was recalled, and Sir M. Hicks Beach, then colonial secretary, refused to amend the Victorian constitution by British act, seeing that the power of amendment had been deliberately surrendered to the colonial legislature in 1855. On Berry's return to Victoria he was defeated in the assembly and heavily overthrown at the ensuing elections. But James Service, his successor, in his turn tried his hand at council reform, produced a measure that the assembly rejected as insufficient, appealed to the country a second time within five months, and found that he had brought Berry back to power. This time he managed to pass (in 1881) a bill that nearly trebled the number of council electors, shortened its term, increased its membership from 30 to 42, and in other ways slightly modernized it. Success, however, was fatal to him, and within a fortnight after the passage of the bill he was defeated in the assembly and succeeded by Sir B. O'Loghlen at the head of a moderate and peace-loving ministry, too weak to effect (even if it had wished to do so) any important changes. For two years the country enjoyed a welcome rest; then the elections of 1883, fought on no particular party cry, swept away the moderates and sent back Berry and Service with about the same number of followers. A coalition was obviously the best way out, and although Service had refused to join Berry in 1880, Berry wisely agreed to join his former opponent and leave him the nominal premiership. The results were excellent. Both leaders were able to select the best of their followers for office, instead of having to fill up the minor offices with extremists—Alfred Deakin, for instance, was thus brought in by Berry—and, the hotly controversial questions having been disposed of, time was given for useful legislation like the public service act (establishing entrance by examination and control by a non-political board) and the railways management act, which similarly removed the construction and control of railways from political interference. A discipline act that to some extent organized the colony's defence, a mallee lands act that threw open to farmers millions of acres in the north-western corner of the colony, and a water conservation act that encouraged the development of the Murray valley lands by irrigation, were other products of this useful coalition.

By this time, however, Berry was ageing, and weary of political life. In February 1886 he resigned office to take the colony's agent-generalship in London (as Service retired at the same moment, a new coalition had to be constructed, Gillies taking Service's place and Deakin Berry's). As agent-general the new official, along with Service, Deakin, and Lorimer, represented Victoria at the colonial conference of 1887. Quiet work in a London office, however, did not suit him for long. In 1892 he handed over the agent-generalship to James Munro, returned to Melbourne, and took the treasurership under Munro's colleague William Shiels; but the financial crisis of 1892-3 was already impending, two banks with which Berry was closely connected had closed their doors even before he took office, and in January 1893 the Shiels ministry disappeared to make room for one more trusted by the mercantile community. When this ministry also failed to master the situation, it was expelled on 28 August 1894 by George Turner (who had been minister for customs under Shiels), and he very wisely provided for Berry's absence from the political combat by making him speaker of the assembly. This post he held until in 1897 he lost his seat in parliament; then he retired on a pension of £500 a year, and died at Melbourne on 25 January 1904. During his last years—in 1891 and 1897-8—he represented Victoria at the two great federal conventions, but left no mark on them. (K.C.M.G., 1886.)

Bevan, Llewelyn David (1842-1918), born at Llanelly in Carmarthenshire, Wales, on 11 September 1842 and educated at University College school and the university of London (B.A., 1862; LL.B., 1865), began his ministry as colleague of Dr. Thomas Binney at the Weigh House chapel in London, at the same time assisting from 1866 to 1876 in the work of the Working Men's College that F. D. Maurice had founded in 1854, and becoming a member of the London school board (1873-6). In 1874 he visited the United States, in 1876 became for a time pastor of the Brick Presbyterian church in New York, and in 1880 was moderator of the New York presbytery. Returning to London in 1882, he was made minister of the Congregational church at Highbury Quadrant, and thought of entering politics; three seats in Wales and one in North London were put at his disposal. In 1886, however, he was invited by the members of the Congregational church in Collins-street, Melbourne, to become their pastor; he accepted, and worked there for 23 years, moving in 1909 to Adelaide to become the first principal of the Parkin training college for Congregational ministers. He died in Adelaide on 19 July 1918.

Outside his ministerial duties Bevan had two great interests, education and the welfare of the workers. At the Melbourne international exhibition of 1888 he was chairman of the jury of education, and was decorated for his work by the French government, and in 1891 was commissioned by the Victorian government to study the educational systems of France, Germany, and the United States. During the London dockers' strike of 1889 he organized a public meeting, under the auspices of the Congregational Union and the Trades Hall council, to raise funds for the families of the strikers; in 1892 he was one of the promoters of a scheme for labour colonies. He was also a strenuous worker for Australian federation. In his own Church he was chairman of the Victorian Union in 1887-8, and vice-president of the international councils at London in 1891 and Boston in 1899.

Beyeria, a genus of the family Euphorbiaceae, containing 13 species (all endemic in Australia) of shrubs with more or less glutinous leaves. The flowers are unisexual. *B. viscosa*, the Pink-wood of Tasmania, is a tall shrub. At times a resinous substance exudes abundantly from its leaves. The wood is used for sheaves of blocks and turnery; it is remarkable for hardness, and for uniformity of colour—a pale reddish mahogany—and of grain.

Biddy-biddy Burr. See Acaena.

Bidens, a genus of the family Compositae, consisting chiefly of weedy herbs, widely distributed throughout Australia. Its floral bracts are few, in 2-3 rows; fruits flattened or 4-angled, surmounted by a pappus of 2-4 rigid

awns set with reversed bristles, by which they cling to the coats of animals. In *B. pilosus* the white rays of the marginal florets are only occasionally developed—though this is a common occurrence in plants growing in the Port Jackson district of New South Wales.

Bidwill, JOHN CARNE (1815-1853), born at Exeter in England in 1815, in 1838 migrated to Australia. His original purpose is not certain; he was vaguely connected with a Sydney firm, but had also a desire to settle on the land, and was able, while awaiting the survey of a block of land he had selected at a great distance from Sydney, to visit New Zealand and investigate the botany of the Bay of Islands district. Recalled to Sydney by his firm, he was sent back to New Zealand in 1840, this time to Port Nicholson, and renewed his botanical researches there. These visits resulted in the publication of a delightful book, *Rambles in New Zealand* (London, 1841). From Port Nicholson the firm sent him to Moreton Bay in what is now Queensland, and he there discovered and described the Bunya-bunya Pine (*Araucaria Bidwilli*), specimens and seeds of which he took to England in 1843. By 1844 he was back in New South Wales, and in 1845 visited Tahiti, where he vainly attempted to acclimatize passion-fruit. He was by this time well known as an expert botanist, highly thought of by Sir Joseph Hooker and intimate with P. P. King, William Macarthur and the Macleays; and on 1 September 1847 Governor Fitzroy made him government botanist of New South Wales and first director of the Sydney botanic gardens. Unfortunately the colonial office had independently nominated Charles Moore to that position, and on his arrival in January 1849 Bidwill had to vacate it, but was at his own suggestion made commissioner of crown lands at Wide Bay. Here he continued his botanical studies, but while surveying a road from his district across the thickly wooded ranges towards Moreton Bay was lost in the bush for eight days, and on 16 March 1853 died at Tinana (now a suburb of Maryborough) from the effects of this and similar hardships. While at the Sydney gardens he experimented widely in hybridization, especially with *Amaryllis* and *Hibiscus*.

Bigge, JOHN THOMAS (1780-1843), born at Linden in Northumberland on 8 March 1780, educated at Westminster School and Christ Church College, Oxford (B.A., 1801; M.A., 1804), and admitted to the bar at the Inner Temple in 1806, was in 1815 appointed by the colonial office chief justice of Trinidad. When therefore in 1818 that office, worried by the complaints of the disgruntled free settlers and the perpetual nagging of Jeffery Hart Bent (q.v.), needed a commissioner to investigate the affairs of New South Wales and report on Macquarie's administration and the real value of the colony, Bigge—who had just returned from Trinidad—was selected and given almost dictatorial powers. Macquarie was instructed to make 'an early, if not an immediate, adoption' of any recommendations Bigge might put forward, and was warned that in disregarding them he would incur 'heavy responsibility.' Taking with him as his secretary Thomas Hobbes Scott (q.v.), Bigge on 30 April 1819 left England in the *John Barry*, and reached Sydney on 25 September; within a month he showed his hand by objecting to Macquarie's appointment of William Redfern, an emancipist, to the magistracy, and from that time onwards there was constant friction between them. Bigge at one time declined all further private intercourse with Macquarie; only Scott's persistence healed the breach, and only that because within a few days Bigge left Sydney for Hobart. For the rest of his visit to the various settlements peace was preserved, though some of his suggestions concerning the limitation of building (a matter which was much at Macquarie's heart) must have tried the governor rather severely. On 14 February 1821, after a 17-months' stay in the colony, Bigge returned to England in the *Dromedary*, and set about the preparation of his reports; but the first (on the convict system) did not reach the British authorities until 6 May 1822, the second (on the colony's judicial establishments) was sent to them late in the same year, and the third (on agriculture, trade, religion, finance, land-grants, etc.) is dated 10 January 1823. It thus fell to Brisbane to carry out the huge mass of recommendations, most of which were accepted by Bathurst without alteration, though he was wise enough to give Brisbane a discretion about their immediate adoption or postponement. The constitutional reforms Bigge recommended are dealt with under CONSTITUTIONS, and those relating to the convict system under CONVICTS; for the rest, he vehemently condemned Macquarie's lenience towards emancipists, blamed him for spending too much money on buildings, but otherwise gave a cold approval to his administration. Shortly after Bigge's return he was entrusted with a similar mission to the Cape Colony, and, going there with fewer prejudices and taking a longer time over his investigations, produced better work. In 1830 he was investigating the Hottentot problem in South Africa. Of his later years little is known, but it appears that he died in 1843. His three reports, whatever may be thought of their recommendations, are a valuable—indeed, indispensable—store of facts concerning life and its conditions in the New South Wales of 1819-21.

Birds of Australia. This article deals with (*a*) the birds noticed by early discoverers, (*b*) the history of Australian ornithology, (*c*) the composition and relationships of the local avifauna, (*d*) distribution and migration, (*e*) songs and calls, (*f*) plumage and coloration, (*g*) special habits, and (*h*) the influence of white settlement on their numbers and distribution. A bibliography is appended.

Early Discoveries.—The first record of Australian birds is contained in a letter of Haevick Claeszoon van Hillegom of the ship *Seewolf* to the manager of the Dutch East India Company. He says that on 5 May 1618, in S. latitude 28° 26', he saw a number of birds 'such as a white tern and a few ternlets,' so that he surmised that he was near the land. Altering his course to the northward he sighted the North-west Cape of Australia six days later.

Several other Dutch mariners on voyages to Java subsequently observed sea-birds on the west coast, and Jan Carstenszoon's journal records that he saw herons, water curlews and other wild-fowl in 1623 on the western coast of the Cape York peninsula; but the first to meet with an Australian land-bird was Francis Pelsart, whose ship, the *Batavia*, was wrecked on Houtman's Abrolhos in 1629. On the two

largest islands of the group, now called the Wallaby Islands, he saw 'a number of grey turtle-doves,'—i.e. brush bronze-wing pigeons.

William Dampier, who landed at Cygnet Bay in King Sound in 1688, reported that there were 'a few small Land-birds, but none bigger than a Blackbird, and but few Sea-fowls.'

In 1697 Willem de Vlamingh discovered a river on which were pelicans, shags, divers, and black swans, and named it the Swan River. In the trees on its banks were cockatoos and parrakeets, and 'the song of the nightingale' (reed-warbler?) was heard. Farther north he saw 'footprints of the cassowary' (emu) and in Shark Bay several very large nests (probably of sea-eagles).

On Dampier's second visit to Australia, in 1699, he landed first at Dirk Hartog Island, where 'there were but few Land-fowls; we saw none but Eagles, of the larger sorts of Birds; but 5 or 6 sorts of small Birds. The biggest sort of these were not bigger than Larks; some no bigger than Wrens, all singing with great variety of fine shrill Notes; and we saw some of their Nests with young Ones in them.' On Rosemary Island, one of the Dampier Archipelago, he saw 'a few small Land Birds, and a sort of white Parrots, which flew a great many together' (bare-eyed cockatoos). Of his final landing-place in Roebuck Bay he records: 'The Land-fowls that we saw here were Crows (just such as ours in *England*) small Hawks, and Kites; a few of each sort; but here are plenty of small Turtle-Doves, that are plump, fat and very good Meat. Here are 2 or 3 sorts of smaller Birds, some as big as Larks, some less; but not many of either sort.'

During his voyage along the north-west coast Dampier met with pelicans, cormorants, gulls, gannets, boobies, man-of-war birds, galdens (herons) and curlews. He gives special descriptions of certain sea-birds which struck him as new; these seem to have been the Caspian tern, crested tern, brown-winged tern, pied oyster-catcher, straw-necked ibis and red-necked avocet. The four last-named are figured in the account of his travels—the first published pictures of Australian birds. The oyster-catcher and avocet are readily recognizable, but the identity of the tern and ibis are more doubtful.

Nothing further was added to the knowledge of Australian birds until Captain Cook, with the naturalists Banks and Solander, landed in Botany Bay in May 1770. No connected account of the natural history discoveries made on this voyage was ever published. Banks in his *Journal* (which was not published till 1896) gives the following account of the birds met with on the coast of New Holland. 'Of sea-fowl there were several species; gulls, shags, solan geese or gannets of two sorts, boobies, etc., and pelicans of an enormous size; but these last, though we saw many thousands of them, were so shy that we never got one, as were the cranes also, of which we saw several very large and some beautiful species. In the rivers were ducks which flew in very large flocks, but were very hard to come at; and on the beach were curlews of several sorts, some very like our English ones, and many small beach birds.

'The land birds were crows, very like if not quite the same as our English ones, most beautiful parrots and parroquets, white and black cockatoos, pigeons, beautiful doves, bustards and many others which did not at all resemble those of Europe. Most of these were extremely shy, so that it was with difficulty that we shot any of them. A crow in England, though in general sufficiently wary, is, I must say, a fool to a New Holland crow, and the same may be said of almost all if not all the birds in this country. The only ones we ever got in any plenty were pigeons, of which we met large flocks, and of which the men who were sent out on purpose would sometimes kill ten or twelve a day. They were beautiful birds, crested differently from any other pigeons I have seen' (i.e. top-knot pigeons). 'What can be the reason of this extraordinary shyness in the birds is difficult to say, unless perhaps the Indians are very clever in deceiving them, which we have very little reason to suppose . . . . Yet one of our people saw a white cockatoo in their possession, which very bird we looked upon to be one of the wariest of them all.'

In addition to the birds mentioned in this summary, Banks notes in his *Journal* that at Botany Bay they shot 'loryquets,' and quails very like those in England; on the Endeavour River they saw whistling ducks; and on Eagle Island in the Barrier Reef found an eagle's nest containing young birds, 'and another I knew not of what bird, built on the ground, of a most enormous magnitude,' 26 feet round and 32 inches high—probably that of an osprey.

In February 1772 a French expedition under Marion du Fresne landed at Frederick Henry Bay, Tasmania. From the journal of Crozet, the chief officer, we learn that the crew 'killed some ravens similar to those in France, some blackbirds, thrushes, turtle-doves' (brush bronze-wing pigeons), 'a parrakeet resembling a South American one in plumage with white beak. They killed all sorts of sea-birds, especially pelicans, and a black bird with red beak and feet, and which Abel Tasman mentions in his journal' (black oyster-catcher).

Captain Cook on his last voyage landed at Adventure Bay, Tasmania, in January 1777. He records 'several sorts of birds, but all so scarce and shy, that they are evidently harassed by the natives, who perhaps draw much of their subsistence from them. In the woods the principal sorts are large brown hawks or eagles, crows nearly the same as ours in England, yellowish paroquets and large pigeons. There are also three or four small birds, one of which is of the thrush kind. On the shore were several common and sea-gulls, a few black oyster-catchers or sea-pies, and a pretty plover of a stone colour, with a black hood (hooded dotterel). About the lake behind the beach, a few wild ducks were seen; and some shags used to perch upon the high leaf-less trees near the shore.' Among the small birds referred to by Cook were the well-known blue wren, the striped diamond-bird and the 'blue jay' (black-faced cuckoo-shrike) the latter being probably the bird of the thrush kind he mentions.

History of Australian Ornithology.—The first scientific descriptions of Australian birds were based on drawings and descriptions—in a few cases on skins—taken to Europe by various members of the expeditions alluded to above or by the first settlers. By the year 1801 about 120 Australian birds were known to naturalists, the majority having been described by the leading English ornithologist of the period, Dr. John Latham. Of the paintings used by Latham in this work a duplicate set, with slight differences, is preserved in the British museum; it is known as the Watling drawings, one of the artists having been Thomas Watling (see ART). It is certain that these drawings, which number

295, were the work of several different hands; many are excellent pictures, but a certain number are so unlike any known bird that it is impossible to guess what species they are intended to represent. Sometimes there are three or four pictures of the same species, of varying merit. As a consequence Latham's descriptions cannot always be identified, and he sometimes gave separate names to what we now know were duplicate pictures of the same bird. Out of the 171 names which he bestowed nearly 100 are still in use.

In 1813 John Lewin published in Sydney a book (illustrated with hand-coloured engravings) called the *Birds of New South Wales*, which is of interest as the first separate work on Australian ornithology. He only described four species that had not been previously named by Latham.

The next ornithologists to deal with Australian birds were mainly foreigners. The Frenchman Vieillot in the years 1816-1819 wrote the ornithological articles for the *Nouveau Dictionnaire d'Histoire Naturelle*, and there described many Australian birds collected by various French exploring expeditions, particularly those obtained by Péron and Lesueur on Baudin's expedition. Of some 70 birds thought by him to be undescribed more than half had been previously named by English writers, but about 25 species are now known by his names. A year or two later Temminck's work on the pigeons of the world named most of the Australian species, and Kuhl, who published a book on parrots, named many Australian species for the first time.

In 1827 Vigors and Horsfield made a study of the collection of Australian birds in the possession of the Linnean Society of London. It seems probable that a great part of this collection had been procured for Sir Joseph Banks by George Caley (q.v.)—at all events Vigors and Horsfield were able to quote from Caley's notes on the habits of the birds, and to give their aboriginal names. Their paper gives us some idea of the birds found about Sydney in very early days and, as might be anticipated, shows that some species then common in the district are now almost unknown there. About 25 species were described as new, and a number of forms were recognized as generic types peculiar to Australia. It is to Vigors and Horsfield, and to some extent to Vieillot, that the first attempts to classify Australian birds must be credited.

The extremely important work of John Gould is described under his name; it need only be said here that since the publication in 1865 of his *Handbook to the Birds of Australia* only about 100 new species have been discovered, and many of these are rare or casual visitors from oversea. The progress of Australian ornithological literature since Gould is sufficiently indicated in the bibliography attached to this article.

Composition and Relationships of the Australian Avifauna.—The total number of species of birds admitted to the official list compiled by a committee of the Royal Australasian Ornithologists' Union is 712. Larger numbers have been given previously, but in accordance with modern views a number of geographical races or forms, only differing slightly, are now regarded as subspecies instead of being given full specific rank.

Of the 712 species 6 are probably extinct, and 42 have been met with on so few occasions that their exact status is not known—most seem to be merely casual or irregular visitors, 48 are regular visitors which do not breed in Australia, and 616 have been found breeding.

The 48 regular visitors include 18 sea-birds which breed farther south and visit Australian coasts during winter, and 30 birds which breed in north-eastern Asia and visit Australia during summer (the northern winter); 28 of these are waders (q.v.) and the other 2 swifts (q.v.).

The 616 species which breed in Australia are grouped in 286 genera in the list already mentioned. The classification of these genera into families is by no means settled, since a large proportion of our birds have not yet been studied anatomically. The latest classification, that of Mathews and Iredale, appears to the writer to be the most satisfactory yet proposed.

The 616 species are arranged by them in 99 families. In the following table these species, genera and families are grouped according to their distribution:—

Distribution.	Species.	Genera.	Families.
Not found outside Australia	431 (= 70%)	107 (= 37%)	11 (= 11%)
Found in other parts of the Australian region (Moluccas, New Guinea, New Caledonia, or New Zealand)	122 (= 20%)	64 (= 22%)	17 (= 17%)
Found in the oriental region (tropical Asia or Malay Is.)	26 (= 4%)	33 (= 12%)	7 (= 7%)
Widely distributed in the eastern hemisphere	19 (= 3%)	30 (= 10%)	17 (= 17%)
Found in the warmer parts of both hemispheres	.....	4 (= 1%)	3 (= 3%)
Cosmopolitan (or absent only from South America)	9 (= 1%)	35 (= 12%)	38 (= 38%)
Oceanic, widespread in tropical or southern seas	9 (= 1%)	13 (= 5%)	6 (= 6%)

Omitting oceanic birds, 54 species, 102 genera, and 65 families of Australian birds are found outside the Australian region, and it is noteworthy that every one of these, without exception, is found also in southern Asia. It is evident, therefore, that a large part of the present avifauna of Australia has reached this continent at different periods from that region. In some cases the birds have undergone so much modification as to be ranked as generically distinct, in other cases only as distinct species; in 54 cases only slight sub-specific modifications have taken place. Probably the slow influx of Asiatic birds via the Malayan and Papuan islands is still in progress. The fact that 90 per cent of our species and 59 per cent of our genera are peculiar to the Australian region indicates the length of time during which Australia has been isolated from Asia.

Since it is the members of the families peculiar

to the Australian region that give the special character to our avifauna, these are here enumerated. The 11 families peculiar to Australia are:—Dromaeidae (emus), Cereopsidae (Cape Barren goose), Anseranatidae (magpie goose), Pezoporidae (ground parrots), Polytelitidae (long-tailed parrots), Leptolophidae (cockatoo parrot), Menuridae (lyre-birds), Atrichornithidae (scrub-birds), Falcunculidae (shrike-tits), Sphenostomidae (white-faces and wedge-bill), Pardalotidae (diamond-birds). The 17 other families peculiar to the Australian region, and represented in Australia, are:—Casuariidae (cassowaries), Megapodiidae (mound-builders), Platycercidae (broad-tailed parrots), Loriidae (lory-parrots), Cacatuidae (cockatoos), Proboscigeridae (palm cockatoo), Trichoglossidae (lorikeets), Opopsittidae (lorilets), Scythropidae (channelbill), Podargidae (frogmouths), Aegothelidae (owlet nightjars), Sphecotheridae (figbirds), Orthonycidae (log-runners), Cracticidae (butcher-birds and magpies), Meliphagidae (honey-eaters), Ptilonorhynchidae (bower-birds), and Paradiseidae (birds of paradise).

A number of these families only contain one or a few species but the broad-tailed parrots, cockatoos, lorikeets, butcher-birds, magpies, diamond-birds, honey-eaters and bower-birds are among the best represented families in our fauna, the honey-eaters being the most numerous family. One or more species of each of these last-mentioned families is present in almost every part of the continent.

The peculiar families are presumably representative of the earliest forms of bird life which reached Australia, and it is therefore of interest to enquire whether they give any clue as to the origin of those forms. The various peculiar families of parrots and of perching birds, together with the channelbill, undoubtedly have their nearest relatives in the old world. The megapodes are generally regarded as coming nearest to the curassows of tropical America. No definite pronouncement can be made as to the lyre-birds, scrub-birds, frogmouths and the two anomalous geese, but it has been suggested that the emu and cassowary have their nearest living relatives in the South American rheas. It would seem probable that whereas the majority of Australia's peculiar birds are descended from ancestors hailing from Asia, the megapodes may be descendants of a curassow-like bird which made its way across the Pacific from one island group to another, and that the cassowary and emu, with the extinct New Zealand moas, are ancient types which originated in the southern hemisphere before the land which formerly connected Australasia with South America across the Antarctic continent sank beneath the ocean.

Distribution and Migration.—Within Australia three very distinct ornithological regions may be distinguished, the Torresian, the Bassian and the Eyrean. The Torresian fauna has its richest development in north-eastern Queensland, extending thence along the coast westward to the Kimberley division of Western Australia and southward to northern New South Wales. Among the birds confined to this region are the cassowary, scrub-fowl, brush turkey, jabiru, crested hawk, coucal and sunbird. Pigmy-geese, figparrots, pittas, log-runners, figbirds and riflebirds are unknown in other parts of Australia, and it is far richer than the other regions in fruit-pigeons, bower-birds and flycatchers. Most of the characteristic Torresian birds either extend to New Guinea or have close relatives therein, 71 per cent of the genera occurring also in the Papuan region. The Bassian fauna has its richest development in the coastal districts of southern New South Wales, Victoria and South Australia, extending also to Tasmania and the south-western corner of Western Australia. Forms peculiar to it are the Cape Barren goose, mountain duck, ground parrot, pilotbird and bell miner; lyre-birds, scrub-birds, bristle-birds, spinebills, wattle-birds and robins (*Petroica*) are characteristic. Some of the latter extend northward into southern and central Queensland, there being a considerable overlapping of Torresian and Bassian forms in this part of the continent; the Torresian birds are mostly confined to the scrubs and the Bassian species found in open bush country.

The Eyrean region comprises the whole of the rest of the continent. In the arid regions of the centre and north-west birds are comparatively few; but all round the edges of the region, in the pastoral areas of the various States, birds are specially numerous. Among the noteworthy Eyrean birds are the mallee-fowl, plain wanderer, cockatiel, budgerigar, red-backed kingfisher, white-winged chough and grey jumper; characteristic types are the bare-eyed cockatoos, grasswrens, ground-birds, scrub-robins, ground-wrens and white-faces, and grass-finches and groundpigeons are specially numerous.

Comparatively few species are found all over the continent. Among these are the emu (which is thus specially suitable as a national emblem), bronze-wing pigeon, white-fronted heron and several other waterfowl, black swan, black duck, grey teal, bustard, tawny frogmouth, magpie-lark, wagtail, wedge-tailed eagle, and several hawks and owls.

It has been mentioned above that 48 species from other regions visit Australia regularly during the season when their breeding-grounds are frozen. The 30 which come from the northern hemisphere form part of the great wave of birds which annually flows to and from the north polar lands, and about which so much has been written. It is interesting to note that genuine migration on a small scale occurs also among southern birds. Eighteen sea-birds that breed on islands farther south regularly visit our southern coasts during winter, and some of the oceanic birds that breed off our coast (notably the mutton-bird of Bass Strait) apparently actually cross the equator into the North Pacific during the southern winter.

In the Bassian region a considerable number of insectivorous birds migrate northwards for the winter. From Tasmania and parts of Victoria the welcome swallow, tree swallow, and wood swallow disappear in the autumn, though in the more northern parts of the region some members of these species are resident. The reed-warbler, dollar-bird, bee-eater, two species of caterpillar-eaters and four species of flycatchers, leave the Bassian region altogether in winter and apparently migrate to the extreme north of Australia, the majority crossing Torres Straits into New Guinea. We have at present little evidence as to the routes followed by most of these birds or their exact wintering-grounds; great flights of bee-eaters, however, are seen crossing Torres Straits northward in the autumn and southward in the spring.

That many insectivorous birds should leave Tasmania and southern Australia during the winter does not seem surprising. It is more remarkable that from the Torresian region also there is a considerable migration northward

for the winter months. The most noteworthy of these migrants are the nutmeg pigeon and the shining starling. So long ago as 1842 Jukes, the naturalist in H.M.S. *Fly*, expressed surprise that birds should leave the tropical forests of northern Queensland for those of New Guinea. 'In these latitudes' he says 'mere temperature cannot be the cause of it, although the variations of the seasons for different fruits or insects may.'

The type of migration which Seebohm called gipsy migration is very characteristic of Australia, especially of the Eyrean region. In dry seasons large numbers of Eyrean birds travel outwards from the interior, and may appear in quantities even on the coast. Immense flocks of black-tailed native hens occasionally invade the suburbs of Perth and Adelaide, and white-browed wood swallows are in some years abundant near Melbourne. In some cases it is difficult to draw the line between gipsy movements and true migrations. Most of the Australian cuckoos apparently pass the winter in the Eyrean region, invading the coastal districts during the breeding-season; their numbers appear to fluctuate somewhat according to the season. The four species, however, which regularly visit Tasmania must there be regarded as true migrants. The two species of song-larks travel annually southward into the Bassian region for the breeding-season, but their abundance varies greatly in different years; apparently when there is plenty of grass in the Eyrean region the majority remain there to breed, and only a few migrate. Other well-known gipsy migrants are the chats, the cockatiel and the budgerigar.

Gipsy migration forms a link between true migration and mere local movements. The flame-breasted robin, which breeds in Tasmania and the mountainous parts of Victoria and New South Wales, winters in western Victoria and South Australia for the most part, though a few remain in sheltered localities near the breeding-grounds. It is certain that great numbers cross annually from Tasmania to the mainland. The rose-breasted robin, which breeds in the mountains of Victoria and New South Wales, travels to the lower country on the east coast in the winter, when many also appear in southern Queensland. In many other species the birds that breed in mountainous or bleak situations move away in winter, probably to the north, whereas those frequenting sheltered valleys and the coastal plains remain in them all the year round.

Properly conducted ringing experiments on a large scale, such as are now in vogue in the United States and Europe, are badly needed in Australia to elucidate the movements of the birds. A study of migration on the comparatively small scale on which it occurs here would probably throw light on the origins of the extraordinary movements of birds witnessed in the northern hemisphere.

Songs and Calls of Australian Birds.—Gordon's well-known reference to Australia as a land of 'songless bright birds' has constantly been taken to mean that all Australian birds are songless, whereas in the writer's opinion he referred merely to the fact that parrots—his 'bright birds'—could not sing. Whatever may have been the poet's meaning, it is certain that Australian birds as a whole are by no means songless. It is probably true that the number of songsters of the first rank is smaller in proportion than in Europe and North America, nor do we enjoy such an outpouring of song as that which marks the spring months in those northern countries; on the other hand the number of Australian birds with melodious songs is at least equal to that found in any other country, and, owing to the lack of inclement winter, the majority of our birds sing throughout the year, though their outpourings are more continuous in the breeding-season.

There is little doubt that the first place amongst our singing birds must be given to the lyre-bird; its own notes are loud, clear and harmonious, its song is well-sustained, and it further shows a wonderful capacity for incorporating in its song the themes of other birds as well as various sounds that it has heard in the bush. The reed-warbler, brown honey-eater, white-shouldered caterpillar-eater, striped honey-eater, bush-lark and song-larks, though their range of notes is much less, rank high owing to the continuity of their efforts and the rapidity with which they pour out their notes, conveying an impression of passionate intensity. The shrike-thrushes, yellow robins, thickheads, and magpies are more accomplished musicians, with a greater command of notes and many passages of beauty, but lacking in fire. Other birds with pleasing songs are the brown flycatcher, fly-eaters, and silver-eyes.

The bush-lark and song-larks sing in the air, like the well-known skylark of England; and the pipit and grass-warbler, though their songs are much inferior, resemble them in this habit. The white-shouldered caterpillar-eater and striped honey-eater habitually sing in tree-tops and often, appearing to be carried away by their own exuberance, leave their perches and float horizontally through the air, singing all the time.

A number of Australian birds utter decidedly melodious calls, which cannot be classed as songs. The most notable of these are the two bell-birds, the crested bell-bird of the Eyrean region and the bell miner of the coastal districts of the south-east. Other striking call-notes are those of the coachwhip-bird, ending in a sound like the crack of a whip; the koel, resembling the familiar cooee; the pallid cuckoo, whistling eagle, channelbill and magpie-lark. The most famous, and perhaps the most remarkable, call of any of our birds is the loud laugh of the laughing jackass; the collared butcher-bird also has a call resembling a laugh. Curious grunting or booming notes are made by the emu, cassowary, bittern, frogmouth and coucal. Most of the cockatoos and parrots utter loud screams, but the remarkable ground parrot appears to be absolutely silent. Of nocturnal calls the 'more pork' call of the boobook owl is the most familiar, and some of the rarer owls utter strange notes at night. The weird and mournful call of the stone-curlew is also usually uttered at night. On moonlight nights the wagtail and the bush-lark, may not infrequently be heard singing. Finally, we may mention the strange song of the restless flycatcher, often uttered while the bird is hovering in the air, which strongly resembles the sound made in sharpening a knife-blade on a grindstone.

The lyre-bird is by no means the only mimic amongst our birds; the spotted bower-bird is also wonderfully clever, and the habit is also possessed by the orioles and rufous scrub-bird. In captivity most species of white cockatoos learn to mimic the human voice as well as other sounds; many Australian parrots, and the magpies, can be taught to whistle tunes.

Plumage and Coloration.—The majority of Australian birds have all the feathers of their plumage normal, but there are a few exceptions. The emu and cassowary have double feathers (see EMU); in the cassowary these are hair-like, but in the emu bear lateral barbs, widely spread on the shaft, which do not interlock—hence the feathers are termed 'disintegrated.' Similarly disintegrated feathers occur in the tails of lyre-birds and emu-wrens, and constitute the nuptial plumes of egrets. The feathers of penguins are scale-like.

Lengthened feathers or plumes occur on the neck of the straw-necked ibis, on the sides of the breast of whistling-ducks, and (in the breeding-season) on the backs of egrets. A pair of long, narrow plumes hangs from the back of the head of the nankeen night heron; in tropic-birds, the white-tailed kingfisher, the bee-eater and the long-tailed grass-finch, two of the central tail-feathers are elongated and project much beyond the others. The whole of the tail of the lyre-bird (q.v.) consists of modified plumes.

Australian birds with lengthened or modified feathers forming a crest on the head are the crested penguin, which has a row of long plumes on each side of the crown; the great crested grebe, which has a tuft on each side of the crown as well as a ruff round the neck; the top-knot pigeon, with one tuft before and the other behind the crown; the cockatoos, whose crests can be raised or lowered at will; the plumed pigeons, crested pigeon, crested hawk, cockatiel, shrike-tits, crested bell-bird, wedge-bill and golden bower-bird, whose crests are much more rigid than those of cockatoos; and the wood-duck, laughing jackass and bush-lark, the feathers of whose crests are not greatly lengthened.

Many honey-eaters have tufts of specially silky or spiny feathers on the cheeks; the white-eyes have a ring of small silky feathers round the eye; the rifle-birds have feathers with a metallic iridescence on the breast; and most ducks and bronze-wing pigeons have a patch of iridescent feathers (speculum) on the wings. In almost all the cases mentioned the modified feathers are coloured differently from those of the adjacent parts, rendering them specially ornamental. Several Australian birds have the whole or part of the head naked. In the ibises and friar-birds the naked parts of the head are black, in the scrub turkey they are red, and in the emu and cassowary blue. Naked patches round the eye occur in the bare-eyed cockatoos and blue-faced honey-eater (where they are blue), in the palm cockatoo, channelbill and figbird (where they are red), and in the cormorants, where they are variously coloured.

Fleshy, pendent wattles are present on the cheeks of the spur-winged plovers and yellow wattle-bird (where they are yellow), on the cheeks of the red wattle-bird (where they are red), on the edge of the gape of the wattled honey-eater (where they are purple), and on the sides of the neck of the cassowary, where they are orange. The jacana has a fleshy comb of a bright rose colour; the leatherhead and helmeted friar-bird have black leathery protuberances on the upper mandible of the beak; the musk duck has a leathery flap hanging from the lower mandible. Smooth horny plates on the forehead occur in some of the rails; in the moorhens and bald coots they are scarlet, and in the coot white.

The proportion of brilliantly plumaged birds in the Australian avifauna is at least as great as in any other region; the highest percentage occurs among the Torresian birds which inhabit the tropical and subtropical scrubs and brushes. Families of which almost all the members are brilliantly clad are the parrots, lorikeets, fruit-pigeons, kingfishers, bee-eaters, pittas and finches. Many honey-eaters and flycatchers are also adorned with bright colours. Among robins, thickheads, wrens, chats, mistletoe-bird, sun-bird, bower-birds, and rifle-birds the males are nearly always brightly coloured, but the females are mostly clad in sober hues. Except the birds just mentioned few show any great difference in coloration between the sexes; among them are the king quail, blue-billed duck, darter, gang-gang cockatoo, log-runners, figbirds, caterpillar-eaters and some of the flycatchers. In most hawks the female is a good deal larger than the male, but male musk ducks and song-larks are much larger than the females. It is remarkable that in almost all the Australian ducks the sexes are similar; this is in striking contrast to what is found in the northern hemisphere, where the drakes of most species are much more brightly coloured than the ducks during the breeding-season.

In most of the birds mentioned above, where the males are more brilliant than the females, the young males—in their first year at least—resemble the females, and some robins, thickheads and wrens at times breed when still in immature plumage. The male satin bower-bird is said to be seven years old before it acquires its complete adult plumage, and it is believed that the regent and Newton bower-birds also take some years to attain full coloration.

In the albatrosses, gannets, gulls, and probably the terns, both sexes acquire a plumage in their first year which is much darker than that of the adult; in the wandering albatross, gannets and Pacific gull the complete adult plumage is apparently not attained for several years.

In many owls, frogmouths and hawks of general brownish plumage there is a great deal of variation in colouring, which does not seem to depend either on age or on geographical distribution. In the brown hawk two distinct forms have been regarded by many writers as distinct species, but intermediates are not uncommon. In the giant petrel, reef heron and grey goshawk white and coloured forms co-exist, though in the two last-named many authors regard the white forms as distinct species. They are not albinos, since their eyes, bills and legs are pigmented, and where they are found in company with the coloured forms they interbreed freely. It is curious that in each case the geographical ranges of the two forms are different; in the giant petrel and reef heron white forms are only found in part of the range of the coloured ones, but the white goshawk has a wider range than the grey, being the only form found in Tasmania and north-western Australia. Dimorphism also occurs in the coucal and black butcher-bird, which have black and brown phases.

A very noticeable feature of Australian bird-life is the predominance of birds with strikingly contrasted black and white plumage. Though the number of species exhibiting this coloration is not very great, most of them are among the commonest and most widespread forms. They include the magpies, butcher-birds, bell-magpies, chough, magpie-lark, caterpillar-eaters, restless flycatcher, wagtail and hooded robin. All these, except perhaps the last, are very bold, pugnacious birds which do not hesitate to attack birds much larger and more powerful than themselves, such

as crows and hawks. They are mostly more or less sociable, though frequently fighting and chasing one another about. It seems clear that this black-and-white style of colouring is an example of warning coloration.

Special Habits of Australian Birds.—It is probable that most of the ornaments described in the preceding section are displayed by their wearers in special ways during courtship. Comparatively few observations on this subject seem to be on record. The male bustards display before the hens in a manner similar to that of the domestic turkey-cock; the male musk duck, when displaying, lowers his head till the flap under the bill is in contact with the water, utters a loud whistle or 'ponk' and at the same moment splashes up the water behind him with his feet; and the male lyre-bird scratches up a mound of earth on which he sings, dances and raises his wonderful tail, while the hen birds watch from amongst the surrounding bushes and ferns. Native companions assemble in flocks and perform strange evolutions that resemble dancing. But the most remarkable type of play is that of the bower-birds (q.v.) which construct bowers round which they collect bones, shells, berries and bright objects of various kinds. The fantails constantly spread the fan-like tail from which they derive their name, and some robins have a habit of drooping their wings; both these actions are indulged in at all seasons, not only during courtship. The crested hawk and the dollar-bird, when flying, frequently tumble in the air like tumbler-pigeons. The nankeen kestrel, black-shouldered kite, brown hawk and restless fly-catcher are able to hover, remaining stationary in the air with rapidly beating wings, while they scan the ground beneath them for food.

Australian birds, like those of other countries, differ greatly in nest-building capacity; some species merely deposit their eggs on the ground; others excavate holes or utilize natural cavities, and others form nests of sticks, grass or fibres of different kinds. Three species—the magpie-lark, chough and grey jumper—build large, basin-shaped nests of mud; the welcome swallow also makes a mud-nest; fairy martins build bottle-shaped mud-nests which are attached in groups to cliffs or houses. Of open, cup-shaped nests those of the robins, white-eyes, most honey-eaters, tree-runners and fantails are the most beautifully formed, the latter being remarkable for the construction of a tail of loose material left hanging. Builders of domed nests include the lyre-birds, wrens, tits and scrub-wrens, the most beautiful structures being those of the mistletoe-bird and sunbird. The crested bell-bird has the curious habit of decorating its nest with hairy caterpillars; the rifle-bird usually twines the cast skin of a snake round its nest. The yellow-rumped tit builds a domed nest containing two cavities; the lower one is lined and utilized for the eggs, and the upper appears to be a sleeping-place for the cock-bird. Babblers build large numbers of domed stick-nests, only a few of which are lined and utilized for breeding purposes.

The laughing jackass and several other species of kingfishers almost always bore a hole in an arboreal termites' nest in localities where these occur; the white-tailed kingfisher and beautiful parrakeet utilize terrestrial termite-mounds for the same purpose.

Most remarkable of all are the great mounds of earth and leaves scratchd up by megapodes (see MOUND-BIRDS), in which the eggs are placed and hatched as in incubators. Australian cuckoos, with the exception of the coucal, deposit their eggs in the nests of other birds (see CUCKOO). Most of the sea-birds, petrels, albatrosses, penguins, gulls, terns, cormorants and pelicans nest in great colonies usually on islands off the coast; many swamp-birds, such as ibises, spoonbills and egrets are also sociable when breeding, constructing nests of sticks in close proximity in trees and bushes growing in the water. The shining starling also breeds in colonies, dozens of their hanging nests being constructed in the branches of some large tree.

A number of Australian birds pretend to be wounded when their nests or young are approached, and flutter along the ground in an effort to decoy the intruder from the locality. This habit is most marked among the ducks, plovers, and chats, but is sometimes exhibited by birds of other families.

The bitterns when alarmed freeze into a rigid attitude, with the long neck and beak pointing straight upwards and the wings pressed close to the sides. In this attitude they are very inconspicuous among the reeds which they frequent. The stone-curlew and frogmouths also adopt a rigid attitude for concealment, the neck being stretched out in front and the eyes almost closed. The curlew crouches on the ground, the frogmouth rests lengthwise on a bough; in these positions their mottled plumage gives them a striking resemblance to a dead bough.

The sordid wood-swallow has the extraordinary habit of roosting in a cluster, the birds hanging on to one another like bees in a swarm.

Influence of White Settlement.—There is no doubt that the settlement of Australia has had a very considerable influence on bird life. The most direct effect is due to the shooting of various species for food or for sport. The birds most sought after by Australian sportsmen are ducks, quail, pigeons, plovers and the bustard. Except in the most closely settled districts these birds do not appear to have decreased very seriously, so that shooting is probably by no means the most important element in the diminution of Australia's bird life. The almost complete disappearance of magpie geese from south-eastern Australia may, however, be due to this cause.

The effect of poison has probably been more serious. In most pastoral areas very large numbers of wedge-tailed eagles have been destroyed by poison-baits intended for dingoes. The poisoning of rabbits has also had a serious effect on certain birds, such as magpies, in some districts.

The fencing of land for pastoral purposes has been very destructive to emus, which have often been prevented from reaching water in times of drought: many, too, are shot because it is believed that they eat too much grass and spread prickly pear.

The periodical burning of pastoral land to improve the grass has probably caused great destruction to ground-nesting birds, though it is difficult to tell how much of the diminution in numbers of the more terrestrial birds is due to fires and how much to the introduction of foxes and cats. Probably these last animals have had the most serious effect of any agent introduced by white men. Certain birds, especially those which nest in holes, have been driven out of parts of south-eastern Australia by the competition of the introduced sparrow and starling, the latter often utilizing all the suitable nesting holes.

The clearing of forest land, especially of the subtropical brushes of northern New South Wales, has almost succeeded in exterminating

certain types of birds that are confined to such habitats, e.g. the Albert lyre-bird.

On the other hand white settlement has undoubtedly increased the numbers of certain species. In the first place the disappearance of the aboriginal, who in the proper season lived largely on the eggs of certain waterfowl that breed in colonies, has enabled many of these birds to breed without interference, and the number of egrets and ibises is probably increasing. Secondly, the clearing of land for agricultural purposes, and the construction of dams throughout the agricultural districts, have greatly benefited birds like the ground-lark, plover, magpie-lark and some others which prefer open country. Probably the familiar wagtail should also be included in this class, as it does not appear to have been a very common bird—at all events near Sydney—when the first settlers arrived.

The foregoing influences are probably the most important; but others, more obscure, may be equally far-reaching. It must not be forgotten, also, that apart altogether from human influence changes are constantly taking place in nature, some species decreasing naturally and others steadily increasing. The study of these changes, and the attempt to arrive at the reasons which favour one species at the expense of another, will always remain a most difficult and fascinating problem for the ornithologist.

Since the settlement of Australia five or six species of birds appear to have become extinct. Of these the small emus of Kangaroo Island and King Island, and the Tasmanian form of the common emu, were certainly destroyed by white settlers. The causes of the disappearance of certain other birds such as the noisy scrub-bird and black-throated coachwhip-bird of Western Australia, the beautiful parrakeet of Queensland, and the night parrot of the spinifex country of the interior, are very doubtful. It is possible that they are not yet quite extinct, but there is evidently no hope of their revival. Some naturalists attribute their disappearance to cats and bush-fires; to the writer it seems probable that they were on the borderland of extinction before the arrival of white settlers. It is noteworthy that several other species of parrots—e.g. the little fig-parrots—have become very scarce even in localities where the scrubs which they frequented have not been greatly disturbed, and such forest-haunting birds, living on fruits in the tree-tops, are out of reach of cats or fires.

While the gradual extinction of some species is taking place, others are undoubtedly still extending their ranges. Tasmania appears to have gained during the past century the white-fronted chat, white-necked heron, white egret and little pied cormorant; south-western Australia has gained the straw-necked ibis, white egret and black-breasted plover. The laughing jackass has been introduced into both these States by human agency, and has become thoroughly acclimatized.

See Lewin's *Birds of New South Wales* (Sydney, 1813); Gould's *Synopsis of the Birds of Australia* (1837-8), *Birds of Australia* (7 vols., 1841-8), and *Handbook of the Birds of Australia* (1865); Diggles's *Ornithology of Australia* (Brisbane, 1866-70); Ramsay's *Tabular List of the Birds of Australia* (2nd edn., 1888); Broinowski's *Birds of Australia* (Melbourne, 1890-1); Hall's *Key to the Birds of Australia* (2nd edn., 1899); Campbell's *Nests and Eggs of Australian Birds* (Sheffield, 1901); North's *Nests and Eggs of Birds Found Breeding in Australia* (Sydney, 1901-14); Hall's *Useful Birds of Southern Australia* (Melbourne, 1907); Mathews's *Birds of Australia* (in course of publication), and *List of the Birds of Australia* (1913); Littler's *Handbook of the Birds of Tasmania* (Launceston, 1910); Lucas & Le Souef's *Birds of Australia* (Melbourne, 1911); Mathews & Iredale's *Manual of the Birds of Australia* (in course of publication); Leach's *Australian Bird Book* (5th edn., Melbourne, 1923); the *Official Check-list of the Birds of Australia* issued by the Royal Australasian Ornithologists' Union; and files of the *Emu* (quarterly since 1901), the *South Australian Ornithologist*, and the *Austral Avian Record* (irregularly since 1912).

Bird's-nest Fern. See FERNS.

Bismuth. Australia was at one time the second largest producer of bismuth in the world, Bolivia coming first. The chief commercial deposits of this metal occur at Kingsgate in the Glen Innes district, and Whipstick in the Pambula district, both in New South Wales. A small quantity has also been mined in northern Queensland and Tasmania. The low-grade ore used to be treated in Sydney, but rich ore was shipped abroad; in recent years, owing to the lack of a market, very little has been treated locally. The method of concentration for the smelters depends on the quantity to be treated and the associated minerals. If the quantity is small, it may be hand-picked, broken up, and concentrated in sluices or on hand-jigs. Larger quantities, that warrant a mechanical plant, are crushed by rock-breakers and rolls, and concentrated in May jigs and on some form of table. For ores associated with molybdenum and wolfram, see under those headings.

Bismuth is mostly used to form alloys with other metals, e.g. copper, tin, lead, and antimony. Small quantities added to lead make it tough: an alloy of two parts of bismuth with three parts of lead is ten times as hard as the pure lead and 20 times as tenacious. Bismuth and antimony form an alloy which expands when changing from the molten to the solid state. Bismuth and tin form a very sonorous alloy, and in consequence many bell-metals have bismuth added to them. Quicksilver absorbs a large quantity of bismuth, and the amalgam thus formed is used for silvering mirrors. Alloys containing bismuth which are fusible at different temperatures are used for obtaining the exact degree of heat for tempering steel. Safety-plugs for automatic fire-sprinklers are made of a bismuth alloy, as also sometimes are electric fuses. Bismuth-bronzes are said to be unoxidizable, to keep a good colour and to be easily polished. Bismuth subnitrate is used in surgical operations, as a medicine, in porcelain painting, and as a cosmetic. The carbonate, oxychloride, salicylate, gallate, lactate, and other organic compounds of bismuth are also used in medicine and surgery. The chief impurities in bismuth are arsenic (which is objectionable when the metal is required for medicinal purposes), tellurium, antimony, copper, and sulphur.

F.D.P.

Biting-lice, also known as bird-lice, small insects of the order Mallophaga, dorso-ventrally flattened parasites without wings, which infest birds and mammals. They have short antennae, with three to five joints; strongly developed mandibles, short legs, and a thorax in which all three segments remain quite distinct. They are rather closely related to the Psocoptera, and may be regarded as a specialized offshoot from near the base of that order, the assumption of parasitism being the principal cause of the evolution of the new ordinal characters. About 120 species are recorded from Australia, nearly one-third of which have been introduced.

The order is divided into two sub-orders, according to the form and position of the antennae.

In the sub-order Amblycera the antennae are four-jointed, more or less clubbed at the tip, and concealed. The maxillary palpi are four-jointed. L. Harrison divides them into six families. The majority of the lice found upon marsupials belong to this sub-order. Among these we may mention the Kangaroo Louse (*Heterodoxus macropus*), and the species of *Boöpia* and *Latumcephalum* found upon wallabies and wombats. All the above belong to the family Boöpidae. The other families infest birds; the best-known genera in Australia are *Eomenopon* (found upon lorikeets), *Ricinus, Colpocephalum, Tetrophthalmus,* and *Menopon.* To the last-named genus belongs the common introduced chicken-louse, *M. gallinae.*

In the sub-order Ischnocera the antennae are either three- or five-jointed, of slender form, and exposed. Maxillary palpi are absent. L. Harrison recognizes three families. Of these the Trichodectidae include species parasitic upon mammals, such as *Trichodectes pilosus,* found on the horse, *T. bovis* on the ox, and *T. ovis* on the sheep; all these have been introduced into Australia with their hosts. The Philopteridae infest birds. The best-known Australian genera are *Philopterus, Lipeurus, Goniocotes, Degeeriella,* and *Rallicola.*

See articles by Johnston and Harrison in the *Proceedings* of the Royal Society of Queensland, 1912, and by Harrison in *Parasitology,* 1916.

Blackall. SAMUEL WENSLEY (1809-1871), eldest son of Major Robert Blackall of the East India Company's service, was born in Ireland on 1 May 1809, educated at Trinity College, Dublin, and served in the regular army and the Irish militia. From 1847 to 1851 he represented Longford in the house of commons; he then served under the colonial office as lieutenant-governor of Dominica (1851-7), governor of Sierra Leone (1862-5), governor-in-chief of the West African settlements (1865-7), and governor of Queensland (1868-71). During his tenure of office in Queensland he paid special attention to agriculture and education, interesting himself particularly in linking up the grammar schools of Queensland with the university of Sydney. He died in harness on 2 January 1871, and was buried at Toowong. He was a tactful administrator at a difficult period of the history of the colony.

Blackberry. See RUBUS and NOXIOUS PLANTS.

Black-bird. See THRUSHES.

Black-caps. See HONEY-EATERS.

Black Drummer. See BLACKFISH.

Blackfish (family Girellidae), a very common market-fish (*Girella tricuspidata*) which is known under various vernacular names in the different States. In Tasmania it is the 'black bream,' and in Victoria the 'black perch,' 'rock perch' or 'ludrick;' fishermen of New South Wales call it 'blackfish,' while in New Zealand it is known as 'mangrove fish,' or 'parore.' It is herbivorous, and line-fishermen usually bait their hooks for its capture with a fine green weed known as sea-moss. It affords excellent sport to rod-fishermen, and puts up a valiant fight for its life; but the bulk of the huge quantities marketed throughout the year is captured with nets in coastal lakes and estuaries. Though not a choice fish, it commands a ready sale—notwithstanding the fact that, like all other weed-eating fishes, it must be cleaned soon after capture lest it become tainted by the weed decomposing within it. Dentition differs in the two sexes, the male having three rounded lobes on the edge of each tooth, while in the female the teeth are chisel-edged. The reason for this is not apparent, but it is so characteristic that the two forms have been generally supposed to represent distinct species. The blackfish is silver-grey in life, tinged with bronze, and has about 12 dark-grey bands descending from the back across the sides. Incipient albino specimens of this and allied species, brilliantly and almost uniformly yellow in colour, are occasionally captured.

Rock Blackfish or Black Drummer (*Girella elevata*) is closely allied to the preceding species, and is not uncommon, though very little has been recorded of its habits or distribution. It is also a weed-eater, but prefers the so-called sea-cabbage. The dentition of the two sexes is the same. It is known only from the neighbourhood of Sydney, where it lives among rocks on the coast, and can be captured with hook and line or with the trammel net. Bluefish, another allied species, is dealt with separately under that name.

River or Slippery Blackfish (*Gadopsis marmoratus*) occurs in some streams in Tasmania and Victoria, and in the New South Wales part of the Murray River system. It is of much interest to naturalists, being the only member of its family (Gadopsidae), and is evidently a highly specialized percoid fish, though its relationships are obscure. It is said to attain a length of 24 inches in the southern States, and is both a good food and game fish. A.R.McC.

Blackham, JOHN MCCARTHY, born in Victoria on 11 May 1855, entered first-class cricket in the intercolonial match of 1874, when he stumped one New South Wales batsman and caught three at the wicket. In 1877 he kept wicket in the first Australia *v.* England test match, and out of the 38 matches that followed played in all but four—three in 1885 and one in 1887. In the first match against Stoddart's team of 1894-5 he was badly hurt, and had to retire permanently from cricket. His ability as a wicket-keeper was remarkable, and he set a new standard for that post, standing up to the fastest bowling, rarely allowing a bye. In his 35 test matches he stumped 24 men and caught 36. In 1884, at Lords against the Gentlemen of England, he stumped three men in succession. He captained the Australian elevens which played Lord Sheffield's team in 1892 and the Australian team of 1893, but was too easily worried to be an ideal captain; during the 1892 matches he admitted losing a stone in weight from anxiety. Incidentally, while captain he invariably put himself in last man, a position only once given him by another captain. It is worth record that he was taken to England with the team of 1878 as second wicket-keeper only, W. L. Murdoch (q.v.) usually keeping wicket for the team. See CRICKET.

Blackthorn. See PITTOSPORACEAE.

Black Thursday, 6 February 1851, the day on which an immense tract of country in Victoria was laid waste by one of the most disastrous bush fires known in Australia. Its origin

was ascribed to the carelessness of some bullock-drivers in the Plenty Ranges, but it seems incredible that any fire could have spread so rapidly from a single source. The flames covered almost simultaneously the country round Western Port, the Dandenong forests, and the ranges thence to Mount Macedon and the Barrabool Hills; then, spreading from the Black Forest across the Loddon district, they crossed the Pyrenees and in the end attacked Mount Gambier beyond the South Australian border. The loss of life was unexpectedly small, but that of property was enormous. In Melbourne, owing to a scorching north wind, ashes from Mount Macedon fell in the streets, which were full of dense smoke, and the thermometer at 11 a.m. registered 117°. A full and vivid account of the disaster is given in Turner's *History of Victoria*, i. 331-3.

Black Trackers, aboriginals attached to the police force in several Australian States, who are employed chiefly in tracking criminals and lost persons in outlying districts. The earliest known official reference to the use of aboriginals for this purpose occurs in a memorial of the legislative council (dated 6 September 1825) to Governor Brisbane on the suppression of bushranging; the council recommended that 'small parties composed of three or four soldiers and one or two natives, under the direction of one constable for each party,' should be stationed on the main roads out of Sydney to track and secure highway robbers. Brisbane forwarded this memorial to Bathurst, who ignored the recommendation; but Darling in March 1826 issued a general police order in which he suggested that the most intelligent natives should be attached to police parties. In the hunt for escaped convicts and early bushrangers trackers were used both in New South Wales and Tasmania—the best known being Musquito (q.v.) of the Broken Bay tribe, who was transported to Tasmania in 1813 and for some years afterwards employed to track down bushrangers, including the notorious Michael Howe.

So valuable were the trackers in police work against the aboriginal tribes that in 1838 an effort was made in the Port Phillip district to raise a native police force—a course that had been suggested by Alexander Maconochie (q.v.) as advantageous to the natives themselves. In 1841 Captain Dana, with the assistance of the tribal chiefs, succeeded in organizing a native corps which performed its duties until his death in 1852. It was then disbanded, as the use of these 'Joes' in the mining district excited much opposition. In Queensland a native mounted-police corps was recruited in 1848 by the explorer Frederick Walker; it was disbanded after a few years' service, during which the troopers were responsible for much wholesale slaughter among the aboriginal tribes, but reorganized in 1857 and maintained until 1900, when it was finally disbanded. Troopers were allowed to re-engage as native trackers attached to the general police force. The services of these Queensland troopers were at times engaged by the other States for tracking purposes—the most notable instance being the engagement by Victoria of six troopers under Sub-inspector O'Connor in the hunt for the Kelly gang. The other States, too, recruited native trackers for their regular police forces. 'Sir Watkin,' of the New South Wales force, at the age of 51 distinguished himself highly by his courage and skill during the hunt for the Clarke gang of bushrangers in 1867; he lost an arm in the final fight, and was given as a reward the honorary rank of sergeant-major.

White troopers in outlying districts have at times suffered from the treachery of their trackers, and in the early days some trackers took advantage of their official position to deal cruelly with aboriginal tribes other than their own. But under proper supervision the native police have behaved finely, and their special capacity for their work is indubitable.

In 1919 there were 39 black trackers in New South Wales; 89 in Queensland; 10 in South Australia; 45 in Western Australia; and 27 in the Northern Territory.

Black War, The. See TASMANIA.

Black Wednesday, 9 January 1878, the day (so named as a bitter parody on Black Thursday) on which the Berry ministry dismissed public officials wholesale. The Victorian legislative council had refused to pass the appropriation bill, and Sir G. Berry, on the plea that this refusal deprived him of funds wherewith to pay the officials, proceeded on the evening of 8 January to gazette the dismissal of more than 200 public servants, including county court judges, magistrates, coroners, goldfield wardens, and the heads of important departments. Many of the dismissed men only learned their fate on arrival at their offices next morning; hence 9 January became notorious, although the formal dismissals were dated Tuesday the 8th. Most of the officials were reinstated in the following April, but the opportunity was taken to get rid of several who had made themselves obnoxious to Sir G. Berry. For his assent to this arbitrary act Sir George Bowen, then governor of the colony, was severely reproved by the British government and soon afterwards removed to the Mauritius.

Blackwood. See ACACIA.

Bland, WILLIAM (1789-1868), born in London on 5 November 1789 and educated at Merchant Taylors' school (his name, however, does not appear in the school register), was trained for the medical profession by his father—himself a specialist in obstetrics—and in January 1809 became a surgeon (5th rate) in the navy. In 1813, while serving in H. M. sloop *Hesper* on the East Indies stations, he became involved in a quarrel with the purser; on 7 April a duel was fought at Bombay, which resulted in the purser's death and Bland's trial at Calcutta for murder. The verdict of 'guilty' was accompanied by a strong recommendation to mercy, so that Bland was sentenced only to seven years' transportation. Reaching Sydney early in 1814, he almost immediately received a free pardon, and began to practise his profession, which brought him into contact with the Wentworths and Redfern; from that time he was a close friend and supporter of W. C. Wentworth both in his personal and in his public campaigns. Among the pleasures of this 'younger set' was that of lampooning dignitaries, and occasionally the lampoon had a wider circulation. In 1816 W. C. Wentworth lampooned Colonel Molle (q.v.), and escaped the consequences by going to England; in 1818 Bland, suffering at the time from the unfaithfulness of his wife, lampooned Macquarie and was less lucky—a fine of £50 and 12 months' imprisonment were his punishment. On emergence from prison in 1819 he steadied down, and devoted himself to philanthropic and public affairs. He took special interest in the benevolent asylum, which had been established

by Samuel Leigh (q.v.) and others in 1818; he joined the committee that in 1825 founded the Sydney free grammar school; in 1828 he tried to resuscitate the school, and was its treasurer from 1835 onwards; he was active in resisting Darling's attempt to revive the censorship of the press; and when in 1835 Wentworth founded the Australian Patriotic Association Bland was its secretary, and helped Wentworth to draft two bills for a 'representative' constitution which were submitted to the British government. When the representative constitution of 1842 came into force, Bland was returned along with Wentworth to represent the city of Sydney; he held the seat until 1848, in the ensuing election was defeated by Robert Lowe, but when Lowe resigned in November 1849 regained the seat and held it for another seven months, pressure of professional business then compelling him to leave politics. Under the constitution of 1856 he entered the council as a nominee on 23 March 1858, but vacated his seat on 21 March 1861. He died on 21 July 1868.

It is probable that in the early twenties he visited England, as in 1823 he was passed by the royal college of surgeons as naval assistant surgeon, and in 1826 obtained the rank of naval surgeon; but we have no other evidence for this visit. His work for the Patriotic Association was of great public value. In 1849, while out of the legislature, he republished a series of letters to Charles Buller—written in the name of the association, and signed by Jamison and Wentworth as well as himself—full of valuable information about the constitutional struggle of 1839-41, as well as about the relative values of transportation and free immigration as sources of labour supply. In the same volume (*Letters to Charles Buller . . . . by William Bland*, Sydney, 1849) are contained an attack on the Wakefield theories and the two draft bills mentioned above. In the same year Wentworth introduced into the legislature a bill to create the university of Sydney, and named Bland—who was at the moment chairman of trustees of the Sydney College—as one of the first senators; Lowe (who had not long before ousted him from the council) raked up against him the conviction of 1813, said that no ex-convict ought to be appointed to the senate, and on that issue secured the failure of the bill. Bland at once told him he was a liar and a scoundrel, and in effect challenged him to a duel (see DUELLING); but Lowe evaded the issue, and when the bill was re-introduced Bland's name—tactfully but regretfully—was omitted from it. For Bland's researches into the construction of dirigible balloons see AVIATION.

Blaxland, JOHN (1769-1845), head of one of the most notable pioneer families of Australia, was born at Hemphall near Fordwich in Kent on 4 January 1769, educated at King's School, Canterbury, and trained for the army, rising to the rank of captain in the Duke of York's cavalry. On his father's death he succeeded to the family estates in Kent, and retired from the army to live at Newington near Chatham; but in 1805 he with his younger brother Gregory (on the advice of Sir J. Banks) decided to migrate to New South Wales, and, promising to employ there at least £6000, was allowed by Lord Castlereagh 8000 acres of land, the use of 80 convicts for 18 months at government expense, and free passages and freight for his family and goods—so anxious was the British government at that time to encourage free settlement in the new colony. Gregory came out first, reaching Sydney on 14 April 1806, and at once fell foul of King; it would seem that the Blaxlands felt they were a boon to the colony, while the old naval governors, fully occupied with attempts to maintain discipline, resented the intrusion of free men to whom their disciplinary code could not be applied. John complicated matters still further by taking passage in a whaler of his own, instead of accepting the free government passage, so that Bligh was ordered to give him extra concessions on arrival—an order which Bligh disliked exceedingly. John reached Sydney on 3 April 1807, and by October was deep in Bligh's black books; he 'cared for nothing but making money,' wrote the indignant governor—he bought cheap and sold dear—he dealt in milk and fat cattle instead of farming—instead of using 80 convicts for 18 months, he proposed to use 20 for six years. Bligh's animosity, indeed, was so well known that after the mutiny Johnston at once made Blaxland a magistrate, and was much irritated when his appointee—who obviously wanted only to be granted his rights and allowed to carry on his business—joined with Simeon Lord in objecting to many of Johnston's and Macarthur's proceedings. To protest at headquarters against his treatment by both Bligh and Johnston, John Blaxland sailed for England in September 1808, but on arrival at Cape Town was arrested as one of the mutineers and badly treated. However, during an enforced stay of three years in England (where he was detained to give evidence at Johnston's trial) he managed to convince the authorities that he had been unjustly dealt with, and Macquarie was ordered to carry out in full the original agreement. This he did with much grumbling, his trouble being that cattle-rearing, which the Blaxlands preferred, was less profitable to the colony as a whole than wheat-growing. This ill-feeling endured throughout Macquarie's term of office; yet in a report on his enemies within the colony the governor classed the Blaxlands as 'discontented' only, while Marsden, Oxley, and Jamison were 'discontented and intriguing'—a sufficient proof that John Blaxland, then as from the first, was merely anxious to carry on his business and did not entangle himself in the many quarrels and intrigues of the time. In 1822, however, he became involved in the dispute over Dr. Douglass which troubled Brisbane's term and caused that governor's retirement, being one of the five magistrates whom Brisbane dismissed; so his claims against the colonial government were not settled until Darling's time. Darling then nominated him to the legislative council, in which he sat from 30 January 1829 till its dissolution on 5 January 1843. In July of the same year he was nominated to the new council, but resigned on 13 September 1844, and died at Newington, near Sydney, on 5 August 1845.

John Blaxland was thus one of the few early settlers to dissociate himself as far as possible from local politics. His object in life was to develop his properties and businesses; at Luddenham near the Nepean and near Broke on the Wollombi he bred and fattened cattle which were slaughtered and salted down at Newington, his headquarters on the Parramatta River. His establishment of salt-pans at this place was of very great value to the colony at large. He was as truly a pioneer in cattle-raising as Macarthur was in sheep. But the family

name has gained more renown from a single —but very important—achievement of his younger brother GREGORY BLAXLAND (1778-1853), born at Newington in Kent on 27 June 1778, who by arrangement with John, as already recorded, left England on 1 September 1805, reached Sydney in the following April, and settled at South Creek near Penrith. His relations with the governors for the most part resembled those of his brother; but there was one period soon after Macquarie's arrival (while John was in England attending to the family grievances and Gregory was quietly managing the New South Wales estates) when he enjoyed cordial relations with Macquarie. Gregory in the partnership looked after the breeding of cattle up-country, and in the course of his work explored the gorges of the Nepean above Penrith and interested the governor in the problem of breaking through the Blue Mountains barrier. It was, therefore, with Macquarie's assent and help that in May 1813 he led the first party across the range (see EXPLORATION BY LAND and LAWSON, WILLIAM) and on return received, as did his fellow-travellers, a grant of 1000 acres to be selected in the newly discovered region. But by this time Macquarie, at odds with John Blaxland over the matters already discussed, had taken a dislike to the whole family, and Gregory's achievement never received from him the official notice that was its due. As for the grant of land, Gregory had no wish to settle beyond the mountains; he at first inclined to select a block near Wollongong, but in 1816 sold his privilege for 5s. per acre to John Connell, who had the land located behind Cronulla. Gregory now settled at Brush Farm on the Parramatta, which he had acquired some years earlier. Here he planted a vineyard with vines from the Cape and made the first Australian wine—he gained medals for it from the Royal Society of Arts in England in 1823 (silver) and 1828 (gold); he also experimented with cattle and sheep fodders, and introduced the cultivation of oats for hay and of buffalo-grass. In July 1825 he established saltpans at Newcastle, but these were shut down in May 1827. In January 1827 he was chosen by 'The Third Grand Colonial Assembly of Australia' —that is, by a representative public meeting in Sydney—to take to England and present to the house of commons a petition demanding trial by jury and representative government. His later years are obscure; he is known to have lived for a time at Wollun near Denman on the upper Hunter, but finally settled on the ridge above Ryde, near Parramatta, where he died on 1 January 1853.

Blaze Tree. See CHRISTMAS BUSH.

Blennies, a group of fishes (Blenniidae) represented in Australian waters by many species which are usually too small to merit the attention of fishermen, though their strange and varied forms and habits render them of much interest to naturalists. A number are able to leave the water at low tide and scramble over moist rocks in search of food, the rays of their ventral, anal, and pectoral fins being commonly modified to form finger-like organs with which they clamber about. Various species of *Salarias* may be observed moving over the surface of coral reefs at low tide, while the Basking Blenny (*Lepidoblennius haplodactylus*) is often seen sunning itself on weed-covered rocks on the coast near Sydney.

The Oyster Blenny (*Petroscirtes anolius*) has a long, sabre-like tooth on each side of the lower jaw, and is often found curled up within the shell of an oyster. Whether it actually destroys living oysters is uncertain, but it uses their shells as a nursery for its young, its eggs being deposited in a mass on their inner surface. Various species of weed-fishes (*Cristiceps*) have a curious crest formed by a detached portion of the dorsal fin upon the head. They are strangely marked with colours that harmonize with those of the weeds among which they live, and silver spots on the body and transparent spaces on the fins appear as splashes of light showing through the weeds, and so help to camouflage the fish from hostile observation.

A.R.McC.

Bligh, WILLIAM (1754-1817), born at Tynten in Cornwall in September 1754, entered the navy when eight years of age, and joined H.M.S. *Hunter* when he was 16. Working his way up, as most young officers then did, from the A.B. rating, he was in 1772 appointed master of the *Resolution* under Cook. In 1781 he was promoted lieutenant, saw fighting at the Dogger Bank and at Gibraltar, and in December 1787 was chosen to command the *Bounty* (215 tons), bound for Tahiti to fetch plants of the bread-fruit tree thence to the West Indies, where it was hoped they would become acclimatized. For an account of this notable voyage and its results see BOUNTY, MUTINY OF THE. Upon Bligh's return to England (14 March 1790) a second bread-fruit expedition was arranged; Bligh, promoted commander in 1789 and post-captain in 1790, was given command of the *Providence*, which, with a smaller vessel, the *Assistant*, sailed from Spithead on 3 August 1791, reached Tahiti in April of the following year, sailed from there in the following July with a cargo of bread-fruit plants, delivered it at St. Helena, St. Vincent's, and Jamaica, and returned to England in August 1793. The voyage was completed without noteworthy incident, but the bread-fruit scheme did not flourish, and the West Indian planters preferred plantains. The Society of Arts in 1794 presented him with a gold medal. Resuming his naval duties, he took command of H.M.S. *Warrior*, cruising off Ushant; he commanded the *Director* at the battle of Camperdown, and subsequently the *Glatton* at Copenhagen in 1801; for his services at this time he was personally thanked by Nelson. In 1805, at the suggestion of Sir Joseph Banks, he was appointed governor of New South Wales, and reached Sydney on 6 August 1806. The voyage was a troubled one. Bligh was nominally 'first captain' of H.M.S. *Porpoise*, which was escorting a convoy of transports; but he actually sailed in one of the transports leaving the *Porpoise* (by admiralty orders) in charge of its 'second captain,' Joseph Short. Quarrels arose; Short fired a shot across the bows of Bligh's transport to compel her to obey his signals; Bligh boarded the *Porpoise*, superseded Short, and for the rest of the voyage took command of the whole convoy. At Port Jackson this quarrel had serious consequences. Short, before leaving England, had been given permission to settle in New South Wales, with a promise of 600 acres of land. Bligh refused to regard this promise as valid, and on the complaint of two of Short's officers ousted him from command of the *Porpoise*, which he entrusted to his own son-in-law, then to Lieutenant Symons, and then to Lieutenant Kent. Short was sent to England as a prisoner in the *Buffalo*, tried by court martial in December 1807, and honourably ac-

quitted. From Bligh's arrival in the colony until he was deposed he steadily made enemies. Among his official instructions was one requiring him to put a stop to the traffic in spirits; and the New South Wales Corps (q.v.), at this time the only military force in the settlement, included among its officers some who were thus trading to considerable pecuniary advantage. Again, when Bligh landed, the principal agricultural settlements were on the banks of the Hawkesbury and Nepean; floods had done severe damage to the prisoners' farm-stock, and the legitimate system of barter that took the place of a proper currency had been seriously interfered with. Bligh, to remedy this, slaughtered government cattle and divided them among those most distressed, giving settlers orders on the public store in proportion to his estimate of their power to repay. This, of course, seriously interfered with those vested interests which had found their profit in compelling settlers to receive payment in 'rum.' Bligh also incurred a good deal of odium by bringing to trial before a court, partially constituted of their accusers, certain Irish political exiles who had voluntarily agreed to exile themselves to escape trial, and were now charged with being concerned in a revolt in New South Wales. Six of the eight accused were acquitted, and the other two convicted and punished at the triangles; but the acquitted men were still kept under arrest and treated as criminals. John Macarthur (q.v.), too, soon aroused the governor's ire. Men of their temperament were more likely to invite than to avoid the quarrel, and a series of mutual pin-pricks followed. In 1807 Bligh's bailiff, Andrew Thompson, had a dispute with Macarthur over a promissory note which Thompson refused to honour. Bligh decided in favour of the bailiff—apparently a fair judgment, if not good law. Meanwhile Bligh had revoked certain of Macarthur's leases, and found further cause of quarrel with him over the *Parramatta*; this vessel, owned by Macarthur, had left Sydney for Tahiti with a convict stowaway, who had been allowed to tranship at Tahiti and so escape. This under the port regulations involved the forfeit of a £900 bond, but Macarthur declined to pay, the naval officer refused to clear the vessel, and Macarthur thereupon abandoned her and was ordered by Atkins, the judge-advocate, to appear before him on 15 December 1807. He disobeyed the order and resisted a constable with a warrant; thereupon a bench of magistrates was summoned, he was arrested, committed to the next sitting of the Sydney criminal court (on 25 January 1808), and admitted to bail. Fresh trouble arose at once. Macarthur pressed Atkins for a dishonoured bill, complained bitterly that a man who was his debtor should be appointed to judge him, and applied for a substitute. Bligh refused; on 25 January 1808 the court was constituted of six officers of the Corps, Atkins presiding. Macarthur again protested, and his protest was upheld by the six officers. Bligh called on each officer to appear before him and answer to what practically amounted to a charge of mutiny, and asked their commanding officer to see him that afternoon. Major Johnston replied that he was ill. The next morning Bligh wrote again to Johnston, pointing out that six of his officers stood charged with treasonable practices; but before Johnston received this letter he had heard that serious trouble was afoot, and his reply was to drive hastily from his Annandale house into Sydney, and liberate Macarthur, who had been during the last few days in gaol. Macarthur at once drew up a formal petition to Johnston, 'imploring' him to arrest Bligh and take charge of the colony. (This petition, which is now in the national gallery at Sydney, is in Macarthur's handwriting, but it is certain that very few, and probable that none, of the signatures were attached until after Bligh had been arrested. When a violent measure of this kind has once been accomplished, it is comparatively easy to obtain approving signatures.) Johnston's next act, after meeting his officers and some friends at the barracks, was to send Bligh a formal demand for his resignation:—'I am called upon to execute a most painful duty' he wrote; 'you are charged by the respectable inhabitants of crimes that render you unfit to exercise the supreme authority another moment in this colony; and in that charge all the officers under my command have joined. I therefore require you, in His Majesty's sacred name, to resign your authority, and to submit to the arrest which I hereby place you under, by the advice of all my officers, and by the advice of every respectable inhabitant in the town of Sydney.' At 6 p.m. the Corps, with band and colours, was marched to government house (which then stood at what is now the corner of Phillip- and Bridge-streets) and Bligh was made prisoner. Over the exact circumstances of this arrest there has been much dispute; many witnesses declare that Bligh had concealed himself and was not found until two hours had elapsed, and Bligh himself said, at the subsequent court martial on Johnston, that his captors had a long search before they could find him. Mrs. Putland, his daughter, kept the soldiers as long as she could from entering the house. A soldier, Sutherland, swore that he found Bligh in a bedroom, behind a bed, and 'helped him over it;' another man, Marlborough, swore that he 'collared Bligh and dragged him from under it.' These are the only two witnesses who spoke upon personal knowledge—the rest was second-hand evidence. Bligh asserted that on the approach of the regiment he put on his uniform and at once began to conceal his papers, in the act of which, while stooping behind the bed, the soldiers rushed upon him.

The first act of the new government was to try Macarthur and the rest of the persons accused by Bligh. Charles Grimes, the surveyor-general, was appointed acting judge-advocate, and all the accused were promptly acquitted. On 8 February 1808 Johnston reported the whole affair to his superior officer, Lieutenant-colonel Paterson, then in charge at Port Dalrymple, and the latter ordered the *Porpoise* to be sent across at once to bring him to Sydney; but, learning that Lieutenant-colonel Foveaux (who was lieutenant-governor of Norfolk Island) was on his way to Sydney, Paterson decided to wait until the terms of Foveaux's commission were known. Foveaux reached Port Jackson in July 1808 and administered the government until Paterson's arrival in January 1809. Up to this time Bligh had been confined to government house, but on 30 January was transferred to the barracks; and on 4 February as the result of negotiations an agreement was signed by Paterson and Bligh, the latter was allowed to go on board the *Porpoise* on condition that the ship should proceed to England as soon as 'the wind and weather will admit.' Instead of doing so however, he sailed to Hobart and tried to re-establish his authority there, but on the arrival of an order from Paterson forbidding any communication with Bligh, the officer in charge, Colonel Collins, refused to acknowledge the ex-governor's author-

ity. Bligh remained on board in Tasmanian waters until the arrival of Governor Macquarie in December 1809, when he departed for England. Macquarie had instructions to reinstate Bligh as governor for 24 hours, but owing to the latter's absence from Sydney this could not be done. The persons chiefly concerned in the revolt were brought to trial in England. Along with other post-captains of his year, Bligh was due for promotion to rear-admiral of the Blue in 1810, but was not included in the gazetted list of that year because his conduct in New South Wales was still indirectly under investigation in the trial of Colonel Johnston. The promotion, however, was kept vacant for him, and on 31 July 1811—a day ahead of the other promotions of that year—he was gazetted rear-admiral, his promotion being almost immediately ante-dated to 31 July 1810. In 1812 he was made rear-admiral of the White, and on 4 June 1814 vice-admiral of the Blue; but he never hoisted his flag. In 1812 the Royal Society made him a nautical fellow. He died at Farnham House, Kent, at the age of 63 on 7 December 1817.

For years after his death, while men still lived who had taken part in the events just narrated, his character was the subject of fierce controversy. But facts recently brought to light after being hidden away for generations in state records and family papers make it possible to estimate his character with some approach to impartiality. Of his violent and imperious temper there is no doubt. The narrative of the *Bounty* mutiny, with its disclosure of his overbearing treatment of Heywood and Christian; his quarrel with Captain Short, and its sequelae; and the lenient punishment awarded by his contemporaries to naval officers whom he had court-martialled, and to the officers of the New South Wales Corps (who on the facts of the case should have been shot as mutineers); build up the irremovable impression of an uncontrolled and tyrannical disposition. As far as his struggle against the Corps is concerned, nothing but this lack of control can deprive him of our sympathy. As a military force—which after all was its nominal *raison d'etre*—the Corps could scarcely inspire respect in one of Nelson's captains; he must have considered the officers a mere assemblage of pursers' clerks, and their undeniable connection with the rum industry (which he was pledged to abolish) would but increase his contempt for them. Again, the *Bounty's* long stay at Tahiti, and the contrast between life there and in the ship, would suffice to explain the mutiny even had Bligh been less overbearing. His vile temper, in short, exaggerated but did not cause the explosions of indiscipline of which he was so often the centre, and put him in the wrong again and again when on essentials he was really in the right. At this distance of time, however, these grave defects may be acknowledged without allowing them to hide from us his excellence in other respects. He was a great navigator, bred in the school of Cook, the same that produced Vancouver, and Flinders, and King. His skill as a fighting commander is equally unquestionable. Australians must remember him as the irascible autocrat who burst out upon Macarthur, the creator of the wool industry, with 'What have I to do with your sheep, sir? Are you to have such flocks of sheep as no man ever heard of before? No, sir!' But they, and the rest of the world, may remember him too as the navigator whose skill and indomitable courage preserved the castaways of the *Bounty*, and as the man to whom Nelson, after his Copenhagen victory, could say:—'Bligh, I thank you; you have supported me nobly!'

See authorities given under BOUNTY, MUTINY OF THE. Documents concerned with the New South Wales mutiny are fully set out in the *Historical Records of New South Wales* and the *Historical Records of Australia;* and the Mitchell Library at Sydney has a fine collection of Bligh papers.

Blood-bird. See HONEY-EATERS.

Blood-flukes. The trematode parasites which infest the blood-vascular system of warm-blooded vertebrates (birds and mammals) constitute a well-defined family, Schistosomidae, comprising a few genera. The species found in human beings, oxen, and certain other mammals, all belong to the genus *Schistosoma* (of which name *Bilharzia* is a synonym), while those occurring in birds have been assigned to other genera (*Bilharziella, Ornithobilharzia, Gigantobilharzia, Austrobilharzia*). The Schistosomidae are distinguished from all other trematodes by the fact that the sexes are distinct, the male worms in most cases being shorter and much broader than the more or less filiform female; they are usually found in pairs, the lateral body regions of the male being curved ventrally to form a cavity (the gynecophoric canal) in which the female lies.

Three species of Schistosomidae have been reported from Australia, two of them (*Schistosoma haematobium* and *S. mansoni*) being human parasites, while the third (*Austrobilharzia terrigalensis*) infest the portal system of the common silver gull, *Larus novae-hollandiae.* The presence in Australia of *S. haematobium* is due to the return of Australian soldiers from the South African war, parts of South Africa being badly affected with bilharzia disease (Bilharziosis, Schistosomiasis). The only locality in our continent where the parasite became endemic was a small settlement in Western Australia; a few cases were reported from it in 1912. During the war many Australian soldiers were infected in Egypt by one or other—or even both—species of *Schistosoma.* The third species able to parasitize man, *S. japonicum,* is not known to occur in Australia, its range being China and Japan; it differs from the other two in possessing a practically smooth cuticle; its egg is smaller, more rounded, and provided with a very small lateral swelling. *S. haematobium* and *S. mansoni* differ in regard to the disposition of the genital organs as well as in the shape of the eggs—which in the latter species possess each a lateral spine, while in the former each is provided with a terminal spine. The detection of ova in the excreta (urine or faeces) has a diagnostic value. The eggs of *S. japonicum* are excreted with the faeces; so, as a rule, are those of *S. mansoni;* but the eggs of *S. haematobium* usually make their exit in the urine, and only occasionally in the faeces. Eggs of *S. mansoni* are sometimes voided in the urine.

From each egg, soon after it comes in contact with water, there hatches out a ciliated embryo (miracidium), which must enter a certain kind of pond-snail before it can undergo further development. In the case of *S. mansoni,* the snails belong to the genus *Planorbis; S. haematobium* requires species of *Bullinus;* and *S. japonicum,* species of *Blanfordia.* Within

the appropriate snail there is eventually developed a tailed stage (cercaria), which on escaping into the water swims actively. This cercaria, which is the infective stage for vertebrates gains access to its host either directly through the skin during bathing or washing, or through the mouth whilst drinking. In either case the young fluke, which has by this time lost its tail, eventually reaches the blood-stream, more especially some part of the portal system—e.g. the inferior mesenteric vein and its ramifications, the vesical veins (of the bladder), and the haemorrhoidal veins (of the rectum and lower part of the intestine). It is in these veins that the adult worms are to be found, nearly always in pairs; and it is in branches of them that the eggs are laid, to be ultimately forced through the walls of the tiny vessels into the submucosa and through the mucosa of the bladder in the case of *S. haematobium* (and to a less extent *S. mansoni*), of the rectum in the case of *S. mansoni* (and to a less extent *S. haematobium*), and of the colon in the case of *S. japonicum*. During their passage the eggs injure the tissues, damaging blood capillaries as well as the epithelium of the bladder or lower intestine, and thus give rise, not only to bleeding, but to lesions, which commonly assume a papillomatous form and may even become tumour-like; these may be invaded by organisms causing suppuration. Thus vesical bilharziosis may have associated with it haematuria and a suppurating bladder; the rectal form of the disease may be accompanied by dysentery and the formation of rectal papillomata—which may even protrude through the anal opening; and in the Japanese disease ('katayama,' as it is called) there are fever, diarrhoea, and an enlargement of the liver and spleen.

The repatriation of infected soldiers may thus lead to the establishment of centres of infection. This danger, however, has been greatly minimized by the action of the defence department in maintaining touch with infected men and in treating them; and recent reports show that the majority of repatriated Australian soldiers known to have contracted bilharziosis during the war have been cured with intravenous injections of tartar emetic.

To avoid the establishment of infection centres it is imperative to prevent the access of infected urine and faeces to water, since the latter is necessary for the life-cycle of the parasite. In areas where the malady is known to be endemic the water of ponds or creeks should not be used for bathing, washing or drinking, unless either boiled or filtered and allowed to stand for at least 48 hours; the cercariae apparently being unable to live longer. Chemical treatment of such water has been suggested but the amount of material that would have to be added would make the water unpalatable. The possibility of controlling the various pond-snails liable to act as intermediate hosts, or carriers of the larval stage, is very small. It would be interesting to know what Australian gastropod molluscs can act as hosts for any of the schistosomes; but no research work on this subject has been published.

S. mansoni is widely distributed in Africa, South America, Central America, and the West Indies; *S. haematobium* in Africa and south-eastern Asia (India to Syria); *S. japonicum* in China and Japan.

Blood-root. See HAEMODORACEAE.

Blood-sucking Flies. The habit of sucking human or animal blood is not confined to a particular species or family of flies; but, owing to their economic importance as carriers of disease-germs, etc., it is convenient to deal with most of the various blood-sucking families together. There are seven in all, but the mosquitoes (Culicidae) are discussed separately. The other families are Tabanidae, Leptidae (brachycerous flies of the sub-order Orthorrhapha), Chironomidae, Simulidae, Psychodidae (all three nemocerous flies of the same sub-order), and Muscidae, muscoid flies of the sub-order Cyclorrhapha.

The Tabanidae are usually known in Australia as March flies, elsewhere as horse-flies or gad-flies—but these names are also applied to the Oestridae. About 200 Australian species have been described, of which more than half belong to the typical genus *Tabanus*. The two sub-families, Pangoninae and Tabaninae, are distinguished by the presence or absence of apical spurs on the posterior tibiae. Of the former group the genera *Silvius* and *Buplex* contain species mostly found in northern Australia; *Osca* and *Pelecorrhyncus* are chiefly southern and eastern, the last being only found in Australia and South America. *Osca guttata*, the largest of our March flies, is not uncommon in the coastal districts of New South Wales. The Tabaninae are represented by the genus *Tabanus*, of which many species show an affinity to Asiatic and Malayan forms; those comprised in the sub-genus *Therioplectes* are almost wholly southern.

Little is known of March flies as actual carriers of disease-germs. There is good, though not conclusive, evidence for regarding them as the intermediate hosts of *Onchocerca gibsoni*, the parasite that causes worm-nodules in cattle—a common disease in northern Australia, Queensland, and northern New South Wales. In the Philippines and India these flies have been regarded with suspicion as possible carriers of *Trypanosoma evansi*, the parasite of 'surra.' In northern Africa they have been implicated as conveying the closely allied disease *m'bori* or *el-debab*, caused by *T. soudanense*. One genus (*Chrysops*), represented in Australia by two very rare species, has been proved to be the intermediate host of loa-loa, a filarial worm which infests human beings. Tabanidae may also be mechanical transmitters of disease; one species, *Buplex neocaledonica*, has been blamed in New Caledonia for transmitting anthrax.

Of the Leptidae (which are allied to the Tabanidae) five described Australian species have the blood-sucking habit; the genus *Spaniopsis* is peculiar to Australia and Tasmania, and four of the species are not uncommon near Sydney and on the Blue Mountains in the autumn. The habit of blood-sucking is rare in this family.

The blood-sucking Chironomidae (midges) belong to the genera *Culicoides* and *Leptoconops*, and are commonly known as sand-flies. About

13 Australian species have been described, though it is not certain that all are blood-suckers. *Culicoides molestus* is the common sand-fly of the New South Wales beaches.

The Psychodidae include *Phlebotomus papatasii*, the sand-fly proper of Mediterranean countries, which is a transmitter of sand-fly fever. It is represented in Australia by at least one species with blood-sucking habits (*P. queenslandi*).

The Simulidae (buffalo-gnats) are comprised in a single genus, *Simulium*, of which four Australian species have been described. These flies are numerous inland; they are not known to carry disease, but were at one time regarded as the carriers of pellagra.

One species of the Muscidae, the Stable-fly (*Stomoxys calcitrans*), introduced with Europeans into Australia, breeds in manure, bites cattle and horses as well as man, and has been suggested as a carrier of infantile paralysis. An allied species, *Lyperosia exigua*, has been introduced into the Northern Territory, probably from the East Indies. This species, a close relative of the house-fly of Europe and America, is commonly known as the buffalo-fly, and appears to be rapidly extending southwards. It has already reached the Kimberley district in north-western Australia, and appears likely to extend into Queensland. Though it does not transmit any disease, the buffalo-fly causes severe damage by harassing cattle, and producing on them chronic sores with consequent loss of weight. E.W.F.

Bloodwood, vernacular name of several species of *Eucalyptus;* but the brush or scrub bloodwood is a *Baloghia* (q.v.).

Blowflies, vernacular name applied to insects of the genus *Calliphora* and its allies, which abound everywhere in Australia, from the hot inland plains to the highlands of the dividing ranges. Breeding in countless numbers in dead victims of drought seasons, or in skinned or poisoned rabbits, they have developed a taste for the hinder parts of living sheep. Heavily-woolled sheep and ewes are especially liable to attack, and their hinder parts may often be seen covered with eggs and young maggots, which quickly work their way to the skin. Soon boring this, they cause blood to flow; this attracts more flies; large scabs are formed and broken, and, as the sores become infected with disease, death frequently results. The maggots also not infrequently enter the body by the natural openings, and cause intense irritation, sometimes ending in death. The flies are more troublesome in wet, warm weather than at other times. As a rule a sheep once blown continues to be blown, and gives off an offensive smell that can be noticed at some distance. Many thousands of sheep are lost annually by the attacks of these flies, others are seriously reduced in condition, and the loss of wool—due to the sheep's rubbing itself to allay the irritation—is very considerable. Crutching, or removing the matted wool in the places most liable to attack, is often practised, but is a tedious and costly operation. Various deterrents (mostly with arsenic, sulphur, or carbolic as their main ingredient) are used, but, since the wool is continually growing, have only a temporary effect. In 1913 W. W. Froggatt, government entomologist of New South Wales, established the first experiment station, and has succeeded in ascertaining (*a*) that decaying animal matter, or at least vegetable matter tainted with animal matter, is essential to the breeding of the maggots, (*b*) that various parasites, of which the chalcid wasp (*Nasonia brevicornis*) is the most efficient and most easily bred, would destroy the blowflies in different stages of development. Since 1921 Froggatt has bred millions of these wasps for distribution over the State; and it is considered that in this way, and by systematically burning (or poisoning with arsenic) all carrion on the runs, the pest will be mastered and possibly exterminated.

In houses meat and even cooking-pots are rapidly fly-blown, especially by certain species which are viviparous, laying live maggots instead of eggs. In camp-life blankets are similarly affected if in the least moist through perspiration, and these need constant airing and attention. Fly-doors and window-screens greatly mitigate this nuisance in the house, while food-scraps and greasy water should be carefully covered or buried, not merely thrown on the soil or just covered with earth. The larvae generally burrow into the ground to pupate, but can usually mature otherwise.

The commonest species affecting sheep are *Anastellorhina augur*, *Neopollenia stygia*, and *Chrysomyia albiceps*. The first two are the species most frequently found in houses; but several of the bluebottle flies (*Lucilia* spp.) are also troublesome in the house and to sheep.

Blueberry. This name is popularly given to several species of *Elaeocarpus*, a genus of the family Elaeocarpaceae, consisting chiefly of trees or large shrubs, which has spread from Asia to Malaysia and even to New Zealand. Fourteen species are endemic in Australia. *E. reticulatus* (also known, but incorrectly, as *cyaneus*), which ranges from Tasmania to Queensland, is usually a small tree (rarely reaching a height of 50 feet), and bears a profusion of white bell-shaped flowers with fringed petals; the fruit, a bright-blue, succulent berry, is also highly ornamental. It has a tough, light-coloured wood which has been favourably compared with English ash. The fruit of *E. Bancrofti* is eaten by settlers on the Johnstone River in Queensland. Its timber resembles the American *lignum-vitae*. *E. grandis*, a moderate-sized tree extending from northern New South Wales into Queensland, has large, blue drupes known to children as blue figs, and sometimes, but incorrectly, as quandongs. The aborigines, who also eat the fruit, call the tree 'callangun.' It has a soft, easily-worked wood suitable for brakes on railway carriages.

Bluebottles, vernacular name for Coelenterata of the genus *Physalia*, called in other parts of the world 'Portuguese men-of-war.' They are free-swimming colonial forms, in which the individuals comprising the colony are modified in various ways according to the work they perform. Several species, which are notorious for their dangerous stinging properties, are found in Australian waters. The most prominent part of a *Physalia* is the large pear-shaped bladder containing air which serves as a float, lying horizontally on the water; it is pointed at both ends, and produced along its upper surface into a crest or sail. As a rule this is of a brilliant peacock-blue colour, but orange-coloured specimens are sometimes met with. From the lower surface of the float is suspended a mass of generative buds that look like bunches of grapes, as well as feeding polyps with long tentacles stiff with batteries of stinging cells. There are no organs of propulsion; the float, borne wholly above the surface of the

sea, is carried along by the breeze with the broad end foremost and the tentacles trailing behind. The length of the tentacles varies considerably, but specimens have been observed with tentacles over 50 feet long. Two species of *Physalia* regularly visit our coast. In recent years a third species has made its appearance on the coast of Queensland; it is quite distinct from *Physalia,* belongs to a different genus (*Caravella*), and is closely allied to a species which follows the track of the Gulf Stream.

Some time ago information was collected in Queensland on the effect of stinging by *Physalia.* All the cases investigated seemed to show very similar symptoms, resembling electric shock followed by intense pain, generally fainting and collapse, sometimes profuse sweats and cold skin. Headache, nausea, vomiting, and sometimes paralysis may ensue, with a convalescence of several days; in one case the pain lasted for three weeks. No fatal case in an adult has been reported, but three deaths among children seem well authenticated. Apparently the poison or shock, though insufficient to kill an adult, may kill a child up to 12 years of age. The injury looks like a burn, and the scars in some cases are said to have lasted for years. The best cure is to rub the skin vigorously with sand, both wet and dry; the latter is the quickest to act, but both are efficient in removing the pain. This is purely a mechanical cure. The sand probably destroys the stinging darts and minimizes the amount of poison injected. Applications of soda, ammonia, or Condy's fluid to the sting have proved useful as emergency measures. Recovery after treatment, and usually without it, is complete and permanent. Another form sometimes washed ashore on our ocean beaches after heavy weather is the By-the-wind Sailer (*Velella*). These animals, which are of a deep indigo colour, are often found in swarms sailing along in the breeze, especially in warm latitudes. In *Velella* a vertical ridge (the sail) is placed diagonally across the upper surface of an oblong disk; attached to the lower surface of the latter is a central feeding polyp, surrounded by smaller polyps, generative buds and a marginal fringe of tentacles. A small form, *Porpita,* consists of a disk-like body from which depend polyps and tentacles.

E.A.B.

Blue Crane. See HERONS, EGRETS, AND BITTERNS.

Bluefish, a brightly-coloured species (*Girella cyanea*), plentiful at Lord Howe Island, and occasionally captured on the coast near Sydney, where a headland (Bluefish Point) has been named after it. Though closely related to the common blackfish of New South Wales—which like various allied species is herbivorous—the bluefish is carnivorous, and readily takes a hook baited with fish or with a large white grub (the larva of a longicorn beetle) found in decaying wood. Corresponding with this diet, its flesh is superior to that of its weed-eating relatives, and half-grown examples ('pannies') are choice table-fishes. It attains a length of about two feet and is bright blue in colour when first hooked, with golden spots on the sides; it changes to a dull leaden colour a few minutes after capture. Semi-albino specimens are sometimes caught, which are uniformly yellow.

A.R.McC.

Blue Jay. See CUCKOO-SHRIKES AND CATERPILLAR-EATERS.

Blue Mountain Cypress. See CALLITRIS.

Blue Mountains, THE, a much dissected eastern spur of the main dividing range of New South Wales, which about 30 miles west of Sydney spreads into a north-south ridge visible from most elevated spots on the shores of Port Jackson. For the first 25 years of the colony's existence this ridge was an impassable barrier to any westward extension of settlement. Rising steeply from the western bank of the Nepean, flanked on the north by the even steeper ridge of the Kurrajong and on the south by a region of stony rises and tangled gorges that is not yet well settled, it seemed penetrable only through the cliff-sided valleys of the Grose and Warragamba; but explorer after explorer found these valleys more difficult than the hills above them. The Grose valley, indeed, and many of the branch valleys along the Warragamba-Cox, terminate in cliffs as sheer as those which border them. It was not until Gregory Blaxland (or William Lawson, q.v.) devised the plan of climbing the ridge itself, and keeping along its top instead of dropping into the valleys, that a road across it was found; then, the spur once traversed to Mount York, the Cox valley could be again entered and a passable track discovered over the real main range (which is in those parts no more than a vague watershed) to the western rivers. To this day only two routes lead west from Sydney —Blaxland's over the Blue Mountains, followed by road and rail, and Bell's Line over the Kurrajong and along the northern side of the Grose valley, which for many years has been a rough stock route but is capable of great improvement. The various pre-Blaxland attempts to cross the ridge are narrated under EXPLORATION BY LAND, and the making of the first road under COX, WILLIAM.

Geologically the Blue Mountains are the remains of a huge plateau of Hawkesbury sandstone that lies on a thin bed of chocolate shale; beneath the latter is a thick stratum of Narrabeen sandstone superimposed on Permo-Carboniferous coal-measures. A steep monoclinal fold in the strata accounts for the eastward slope of the plateau, which drops over 3000 feet between Mount Victoria and the Nepean valley. Its extreme dissection is due, first to the shale bed, which weathers rapidly, undercuts the Hawkesbury sandstone, and so produces the sheer cliffs that are characteristic of the area; and next to the underlying coal-measures, in which erosion is rapid and widespread. The huge blocks of sandstone that cumber the valley of the Grose—and made progress up that valley almost impossible to the early explorers—have fallen away from the upper cliffs. Behind the Kurrajong, north of the Grose, an important fault has let down the surface of the main plateau, and thus created a genuine two-sided ridge, whereas the Blue Mountains 'ridge' is merely the seaward face of a continuous slope.

The name 'Blue Mountains' is often used in a vague and erroneous way to denote the whole main range region west of Sydney; thus the Jenolan caves (q.v.) are said to lie 'in the heart of the Blue Mountains,' though they are at least 25 miles from their nearest edge. The name is properly applied only to the sandstone plateau bounded on the north by the Capertee and Colo rivers and on the south and west by the Cox; the Kurrajong ridge, though a part of this plateau, is usually considered a separate area. The name was originally given to the

hills west of Sydney because of the bluish haze that in a warm climate hangs over all hills seen from a distance.

It is to the existence of this 3000-ft. barrier just to the west that Sydney owes its most remarkable meteorological feature—the occasional raging westerly wind (hot in summer, bitterly cold in winter) followed within 24 hours by a southerly wind that comes up the coast and when violent is known as a 'southerly buster.' Across the inland plains the set of air is usually easterly; the Blue Mountains divert this into the upper regions of the atmosphere, and at that level it flows continuously above Sydney, north-easterly winds replacing it at the lower level. When disturbances farther north interrupt the north-easterly current, the west wind drops from the higher level to take its place; but the same lack of pressure that allows this drop also invites an inflow of cold air from the

The Blue Mountains

(valleys on left bank of Nepean shaded). ——— Cox's road - - - Bell's Line

south, so that the westerly summer wind (being hot) cannot blow for many hours. In winter, when both the westerly and the southerly winds are cold, they may fight out between them for some days the possession of the low-lying coastal area.

Blue Thistle. See ERYNGIUM.

Blue Wren. See WRENS.

Blyth, SIR ARTHUR (1823-1891), was born at Birmingham on 21 March 1823, educated at King Edward VI school there, and in 1839 brought by his parents to Adelaide, where he worked under his father as an ironmonger. Living near Mitcham, he became chairman of the district council and member for Yatala in the old legislative council (1855) and for Gumeracha in the new (1857); this seat he held until 1875, with an interval in 1867-9 when he was away in England. He took his share in the troubled politics of the colony, becoming commissioner of works in the Baker (1857) and Hanson (1858-60) ministries, treasurer in the Waterhouse ministries (1861-3), commissioner of crown lands in a ministry of his own (1864-5), treasurer in the Ayers ministry (1865), chief secretary in the Boucaut ministry (1866-7), commissioner of crown lands in the Hart ministry, and finally twice premier (1871-2, 1873-5). During all these years the land question was the most contentious issue, and Blyth's varied political career was mainly conditioned by attempts to harmonize the public good with the public's wishes in this regard. In 1875 James Boucaut (q.v.) put forward an ambitious programme of public works, and defeated Blyth (who now left Gumeracha for North Adelaide), but the next year took him into his ministry as treasurer: on Boucaut's defeat Blyth became agent-general for the colony, reached England in 1877, and resided there till his death on 7 December 1891. Apart from politics (in which he was rather of the permanent official than of the partisan type) Blyth had no special interests, though he was a captain in the volunteer corps raised in Adelaide during the Crimean war, a director of the South Australian Company, and a member of the university council. As agent-general he represented his colony in the colonial conference of 1887. (K.C.M.G., 1877; C.B., 1886.)

Boake, BARCROFT HENRY (1866-1892), son of an Irish father and an Australian mother, was born at Balmain (Sydney) on 26 March 1866, and trained as a surveyor. In July 1886 he became field-assistant to a surveyor in the Monaro district, but after two years preferred the life of a boundary rider and drover on the western plains of New South Wales and Queensland; in 1890, however, he reverted to survey work in the colder climate of the upper Murrumbidgee. At the end of 1891 he returned to

Sydney, but failed to secure work there, and on 2 May 1892 hanged himself at Middle Harbour with the lash of his stockwhip.

This premature close of a career that promised greater achievements was apparently due to the strain of inactive and unprofitable city life telling on a temperament naturally morbid and a weak, slow-beating heart; financial difficulties and the example of A. L. Gordon—whom Boake greatly admired—had their share in it also. Boake's posthumous volume of verse, *Where the Dead Men Lie*, obviously inspired by his recollections of Monaro and the Diamantina, shows promise but little more: and his reputation rests mainly on the one powerful but morbid poem that gives the volume its title.

Boatswain-bird. See TROPIC-BIRDS.

Boldrewood, ROLF. See BROWNE, T. A.

Bolly Gum. See LITSEA.

Bombax, a genus of the family Malvaceae, consisting of trees chiefly found in Central and South America, with one species from tropical Africa. The only species indigenous to Australia is *B. malabaricum*, found also in tropical Asia. Its large trunk and limbs are covered with short, conical prickles; flowers large, red, clustered towards the ends of the branches; leaves with 5-7 leaflets, falling at flowering-time; fruit a large capsule, densely woody inside. It is known in India as the Malabar silk-cotton tree. The young roots have astringent properties. The wood is used for packing-cases and for lining wells. In Burmah the trunk is often hollowed out for canoes. The silky cotton, though pretty, is not suitable for spinning, but is largely used in upholstery for stiffening cushions, etc. A kind of quilt or thick cloth is made from it in Assam.

Bonito, a widely distributed fish (*Euthynnus pelamis*) ranging over all warmer seas. It is an inhabitant of open ocean, rarely venturing into coastal inlets. Though at various times the bonito has been taken off the Australian coasts, and is known to occur in large schools, very little is recorded of its migrations and habits in our waters. The flesh is very red and oily, and is considered to be of so little value as food that the fish is rarely forwarded to the markets; but it is a fine game-fish, and its capture affords excellent sport to rod-fishermen using light tackle.

A.R.McC.

Bonnor, GEORGE JOHN, born in New South Wales on 25 February 1855, played cricket for both New South Wales and Victoria, and was a member of the second (1880) Australian team that visited England, as well as of the teams of 1882, 1884, 1886, and 1888; during the last two visits, however, he did not display his earlier form. He also played for Australia against Ivo Bligh's visiting team of 1883 and Shrewsbury's of 1884-5.

The effect produced in England by Bonnor's physique was remarkable. Ruskin described him as 'a young god,' and E. V. Lucas, writing in 1925, recalled to mind 'the mighty Bonnor, immensely tall, with golden hair and beard . . . this superb figure, like a god from another planet.' But his lasting fame was won by his great hitting powers. His height was 6 ft. 6 in., and he used a bat weighing about 2 lb. 7 oz. Three of his best-remembered feats are (*a*) breaking the clock on the pavilion at Melbourne with a hit from the centre of the ground, (*b*) at Portsmouth in 1882 hitting the wooden sight-screen behind the bowler so hard and so frequently that it was splintered, (*c*) hitting a catch to G. F. Grace at the Oval for which two runs were actually run before the ball descended. Nor was hard-hitting his only virtue; his fielding, especially in the outfield, was brilliant, for he was a fast runner and had an excellent return to the wicket. His batting average in test matches was only 17, but this includes the years of his decline; in 1882-3 his average was 31, and in 1884-5 39.6. See CRICKET.

Bonwick, JAMES (1817-1906), born in London on 8 July 1817 and trained for the teaching profession, after several appointments in English schools was chosen to conduct the model school at Hobart, arriving there on 10 October 1841. In 1843 he resigned and opened a school of his own; in 1849 he moved to Adelaide to open a school there, but joined the rush to the goldfields in 1852, soon lost heart, and in Melbourne failed to make a success of either journalism or land agency. In July 1856, however, he was made inspector of denominational schools in Victoria, and proved excellent at the work; when a coach accident put a stop to his bush travelling, he opened a school at St. Kilda and made a hobby of investigations into early Australian history. In 1856 he had published in Melbourne *The Discovery and Settlement of Port Phillip*, and pamphlets on minor historical subjects appeared later; but it was in 1870, with the publication in London of *The Last of the Tasmanians*, *Daily Life of the Tasmanians*, and *Curious Facts of Old Colonial Days*, that he came into notice as a historian. In 1882 he published what is possibly his best-known book, *The First Twenty Years of Australia*, following it in 1883 with *The Port Phillip Settlement*. In 1884 he visited England, where he resided for the rest of his life, with occasional visits to Australia. He now entered on the task of searching the records office in London for papers relating to Australia, and in 1886 sent out to Parkes, then premier of New South Wales, notes on some important despatches he had discovered. Parkes immediately authorized him to transcribe these and other papers, and in 1888 instructed him to continue his researches as an official of the colonial government, handing over the material thus obtained to G. B. Barton to be used in the making of his *History of New South Wales from the Records*. One volume of this history having appeared, the government decided that the actual records should be made as public as the history derived from them, and in 1893 the first volume of the *Historical Records of New South Wales* appeared. While this and the succeeding volumes were announced as under the editorship of Alexander Britton and F. M. Bladen—and justly so—the mass of the material comprised in them was gathered by Bonwick, and his name also should be remembered in this connection. After the advent of federation the New South Wales government considered that the publication of these records should be taken over by the Commonwealth; the work was therefore suspended, and Bonwick's appointment came to an end. He died at Norwood near London on 6 February 1906.

While his historical work has suffered the fate of all pioneer work of its kind, and has been either embodied in or superseded by later work, it still has value. Coming when it did, however, before the interest of Australians in their past history was properly awakened, it

may be considered invaluable; 'but for the active search made in London by Mr. James Bonwick' wrote Alexander Britton, 'the early records of New South Wales would have been little better than a blank.'

Bony Bream. The so-called Bony Bream (*Nematalosa erebi*) is a freshwater herring, plentiful in many streams in the eastern and central portions of the continent, and apparently extending westwards also. It is closely allied to an estuarine form, *N. come*, which occurs in tropical parts of Australia and in the Indo-Australian archipelago. Both are extremely bony, and of little value as food; they are sometimes called 'hairbacked herrings,' in allusion to a long slender ray that projects backwards from the dorsal fin. A.R.McC.

Bonython, Sir John Langdon, son of G. L. Bonython of the family of Bonython of Bonython and Carclew in Cornwall, was born in London on 15 October 1848, brought by his parents to South Australia while quite young, educated in Adelaide, and in 1864 attached to the literary staff of the Adelaide *Advertiser*. Devoting himself to his profession, he soon became sub-editor and then editor of the paper, and in 1879 joined the proprietary; since 1893 he has been sole proprietor. Always interested in education (he was knighted in 1898 for his services in this respect), he was from 1883 to 1901 chairman of the Adelaide school board, from 1895 to 1902 chairman of the government agricultural college, and has been since 1889 president of the school of mines and industries, which was practically his creation. He is also a member of the Adelaide university council and deputy-chairman of the State's advisory council of education. In 1901 he was elected a South Australian member of the first federal parliament, and re-elected to the second without opposition, but retired from active politics in 1906, and was subsequently made chairman of the Commonwealth literary fund. He was one of 14 trustees appointed by the Australian soldiers' repatriation act of 1916, and one of seven commissioners appointed under the similar act of 1917. (Kt. Bach., 1898; C.M.G., 1908; K.C.M.G., 1919.)

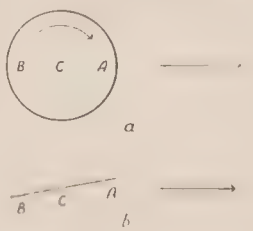
Boomerangs. The weapon most closely associated with the Australian aboriginal is the boomerang, of which there are various forms; some, large and heavy, are used for fighting at close quarters, others for fighting at a distance or for bringing down game, others again mainly for amusement. These (which are met with only in restricted areas) have the characteristic property of curving sharply in their flight and returning to a skilful thrower. In general shape all boomerangs markedly resemble the long, thin, curved leaf of many eucalypts; the blade is usually flat on one side and slightly convex on the other. In some cases one end of the weapon is shaped into a handle. The curve is usually a wide open one, but all grades are found between a scarcely noticeable curve and one in which the two ends are almost at right angles. The property of returning to the thrower (which is discussed below) appears to be associated with a very slight longitudinal twist. The plaything rotates during its passage through the air, and a really skilful thrower can make it describe first a large circle and then one or two smaller circles before it falls at his feet.

Starting from the ordinary throwing-stick, longitudinally straight but rounded in section, a series of weapons can be traced through a curved throwing-stick of circular section to one of elliptical section, then to a slightly flattened form, and so to the normal boomerang described above. From this type-weapon three lines branch—one to the highly specialized 'return' boomerang; a second to a form with one end slightly enlarged, and so to the beaked boomerang and the curved, club-like 'lil-lil;' a third through the handled form to the unwieldy 'sword' met with in Queensland. W.B.S.

The principles underlying the behaviour of a 'return' boomerang may be understood from a consideration of the flight of a disc projected edgeways-on while rotating about an axis perpendicular to its plane. Let (*a*) represent such a disc (the directions of rotation and translation being indicated by the arrows), and let the plane of the disc be vertical. Were it not for the rotation, the disc would quickly turn so that it travelled broadside-on; if it were deflected ever so slightly—as represented at (*b*), where BCA is the plan of the disc—it would experience resistance from the air which has to be pushed aside as it advances. The force due to air-resistance is greater on the front half (CA) than on the rear half (CB), because the air can slip past the latter more easily; so there is a tendency to turn the disc about a vertical axis until it assumes the broadside-on position. While rotating, the disc does not respond to these forces in the same way as when there is no rotation, because there is also a tendency to maintain the original rotation about a horizontal axis perpendicular to the line of flight. The effect of the forces tending to produce rotation about a vertical axis is gradually to change the direction of the axis of rotation from the horizontal towards the vertical; but the axis always remains perpendicular to the line of flight, or very nearly so, so that the plane of the disc is gradually twisted from the vertical towards the horizontal as it advances. Under the conditions represented in the figure the plane of the disc would twist over to the right as we look in the direction of its flight. Such a change of direction of the axis of rotation of a body—where forces are applied which, in the absence of rotation, would cause it to turn about a new axis—is called a 'precession;' it is well illustrated by the behaviour of a rolling hoop, which when deflected from the perpendicular does not fall to the ground, but changes its direction.



In addition to this precession of the axis of rotation towards the vertical, there is a second one (due also to air-resistance) which causes a change in direction in the horizontal plane. On account of the rotation, the velocity of the surface of the disc relative to the air in which it moves is greater in the upper than in the

lower half; so that in the upper part there is a greater tendency for the air to be pushed forward with the disc, and as a result the force due to air-resistance is greater on the upper half than on the lower. This inequality has the effect of checking the rotation, and also tends to cause a rotation about a horizontal axis parallel to the direction of flight; on account of the original rotation, however, what actually occurs is a precession, the axis of the disc turning slowly in a horizontal plane, and with it the direction of advance. In the example illustrated in the figure this second precession would make the disc and its direction of advance turn to the left as we look in the direction of the flight.

There are, therefore, two precessions due to air-resistance, one causing the plane of the disc to twist over to the right or left and the other causing it to turn to the left or right, the direction of advance changing with it. As the plane of the disc departs from the vertical, the path will bend upwards. As the motion continues, the relative importance of the two precessions will change; and this, together with the fact that the path will also change on account of gravity, renders the calculation of the complete path a problem of great complexity even with the simplest of bodies. However, if at any instant we know the direction of the plane and the directions of its rotation and translation, the directions of the two precessions can be determined as in the special case taken here. Experiments made with thin pieces of card, to which a translational and rotational motion are given by flicking them with the finger, illustrate the two precessional effects.

In the boomerang we have a body less simple in form than that considered, but the principles are the same. As a result of the rotation and translation there are two precessions, whose relative importance depends on (*a*) the design of the weapon and (*b*) the initial conditions impressed by the thrower. O.U.V.

Boothby, Benjamin (1803-1868), born at at Doncaster in Yorkshire on 5 February 1803, was called to the English bar in 1825, travelled the northern circuit, and became recorder of Pontefract. In 1853 he was appointed, by letters patent under the great seal of the province, a puisne judge of the supreme court of South Australia, but soon distinguished himself by repeated disagreements with the chief justice, Sir Charles Cooper, so that a third judge had to be appointed in 1858 to facilitate the administration of justice. When Sir Charles went to England on leave, Boothby became acting chief justice; but when Sir Charles resigned in 1861, R. D. Hanson, then attorney-general of the colony, was given the chief-justiceship. Boothby at once challenged this action on the ground that the nature of his own appointment gave him unqualified right to take the senior position, and objected (on the ground that it made no similar provision for other judges) to the South Australian act which gave Cooper a pension. In the end he declared that the constitution act of 1856 was invalid—as well as all laws enacted under its provisions—and postponed the trial of many prisoners arraigned before him on the ground that the soi-disant attorney-general had no legal existence, and therefore could not indict anybody. The whole judicial system was thus thrown out of gear, and the scandal grew so great that parliament petitioned for Boothby's removal from office. The Duke of Newcastle, then colonial secretary, refused to go so far, but secured the passage through the British parliament of acts validating the proceedings to which Boothby had objected. This made no difference to the recalcitrant judge; he maintained his position, and in 1866 a renewed appeal for his removal was made to Lord Carnarvon (Newcastle's successor), who suggested that the colonial authorities should themselves take action. In July 1867, therefore, the governor in council formally removed Boothby from the bench. His intended appeal to the privy council was frustrated by his death on 21 June 1868.

Boothby, William Robinson (1829-1903), son of Benjamin Boothby (q.v.), was born at Nottingham in England on 26 September 1829, and educated at the university of London; he migrated to South Australia with his father in 1853. In 1854 he was made deputy-sheriff and returning officer for the colony, and in this capacity conducted all the elections for 50 years after the establishment of responsible government; from 1856 onwards he was sheriff. Naturally interested in election methods, he prepared both the clauses of the act of 1856 that instituted voting by ballot (q.v.), and those of the act of 1858 that substituted for deletion of the names of unfavoured candidates the placing of a cross against the name of the favoured candidate. (This balloting method is used in all federal elections and referendum polls.) In later years he became comptroller of prison labour, and a senator of the university of Adelaide. He died in Adelaide on 12 July 1903. (C.M.G., 1893.)

A younger brother, Josiah Boothby, born at Nottingham on 8 April 1837, reached South Australia with the rest of the family in 1853, entered the public service during that year, was government statist from 1863 to 1879, and superintended the census in 1861 and 1871. (C.M.G., 1878.)

A nephew, Guy Newall Boothby (1867-1905), gained some fame as a popular novelist.

Boragineae, a large family of herbs (rarely shrubs or trees), the herbaceous genera chiefly found north of the equator, the shrubby species mostly in the tropics. Twelve genera, including 61 species, are indigenous to Australia. The flowers are usually small, frequently arranged in one-sided spikes; fruit a drupe, or dry, and separating into four distinct nuts. The genus *Ehretia* has five indigenous species. *E. acuminata* (Brown Cedar) is a moderate-sized tree with a light brown wood resembling that of the English elm. The genus *Heliotropium* has 23 indigenous species, mostly herbs or under-shrubs. *H. europaeum*, an inland (apparently indigenous) species which is also a common European plant, is developing into a weed in cultivated areas. The exotic *H. peruvianum* is the Heliotrope of our gardens. The genus *Myosotis* is represented by two indigenous species; *M. australis*, a diffuse herb with small white to yellowish flowers, ranges from Western Australia to New South Wales, and extends to New Zealand; *M. palustris* (exotic) is the Forget-me-not of Britain. See Cordia.

Bore-fish. See Spangled Grunter.

Boronia, a genus of the family Rutaceae, endemic in Australia. The calyx-lobes and petals are 4; stamens 8; the filaments thickened

towards the summit; fruit dry with 4 nearly distinct 2-valved carpels, each containing a solitary seed; leaves opposite, entire, or more or less divided into leaflets. *B. serrulata* (Native Rose), a strongly scented undershrub with pink flowers and rhomboid leaves with diminutive saw-like teeth round the margins, is one of the most highly-prized bush-plants in the Port Jackson district, to which it is confined. *B. pinnata* and *B. floribunda* (feathery-leaved species) and *B. ledifolia*, with simple leaves, are the common boronias of the sandstone hills. The variety *citriodora* of *B. pinnata* is the Lemon-plant of Tasmania, an alpine species with a strong lemon scent, which might well be used for the production of citronellol on a marketable scale. The Western Australian *B. megastigma*—flowers brown outside, yellow within—is extensively cultivated in the eastern States for its delicious fragrance. The flowers of this species have been suggested as a flavouring agent for tea, as they resemble in aroma those of *Chloranthus inconspicuus*, used in China for that purpose. In some parts of southern New South Wales

Boronia pinnata.

the leaves of *B. rhomboidea* are chopped up with fodder and given to horses as a vermifuge.

Bosanquet, Sir Day Hort (1843-1923), born at Rock Hall near Alnwick in Northumberland on 22 March, 1843, entered the royal navy in 1857 (lieutenant, 1863; commander, 1874; captain, 1882; rear-admiral, 1897; vice-admiral, 1902; admiral, 1905). He was commander-in-chief of the East Indies squadron (1899-1902) and the North American squadron (1904-7), and then for a year commanded the Portsmouth station. In 1909 he was made governor of South Australia, and held that position till 1914. While his work was mainly of the routine class, it brought him Swedish and Prussian decorations, as well as the British orders enumerated below. He died on 28 June 1923. (K.C.B., 1905; G.C.V.O., 1907; G.C.M.G., 1914.)

Bossiaea, a genus of the family Leguminosae, consisting of shrubs, endemic in Australia. They have cylindrical, flat, or winged stems; flowers orange to red; pods flattened. *B. foliosa*, an erect, graceful shrub, has small orbicular leaves, often only one line long, arranged in regular pairs along the slender branches. The small pods are clothed with a thick coat of silky, red hairs. *B. heterophylla* has compressed, winged branches and leaves with an extreme range of variation in shape and size. In *B. scolopendria* the flattened stems and branches (cladodes) are leafless; the stems perform the function of leaves, as in the phyllodes of *Acacia*.

Bossiaea lanceolata.

Botanic Gardens. Sydney.—Phillip on his way to New South Wales in 1787-8 collected at Rio de Janeiro and Cape Town a number of plants and seeds, and one of his first acts after arrival in Port Jackson was to set apart land for a farm and garden on the cove immediately east of the township, called by the aborigines Wockannagully but by Phillip renamed Farm Cove. The plants from Rio and the Cape, however, were first planted on the slope above the governor's tent—that is, between Phillip-street and Macquarie Place—which thus became the first Australian botanic garden. The farm proved a failure, its soil being barren and rust affecting the wheat; before Phillip left he handed over part of it to Nicholas Devine, a superintendent of convicts; when in 1794 Devine secured from Grose a larger block of land, Joseph Gerrald (one of the 'Scottish Martyrs,' q.v.) was allowed to occupy the Farm Cove garden, but died there after four months' residence on 16 March 1796. From that time on it seems to have been retained as government property, and Phillip's collection of plants was gradually transferred to it. In Bligh's time it was a 'shrubbery' laid out in walks and clumps of trees; Macquarie took through it his road to Mrs. Macquarie's Chair, and on 13 June 1816 formally dedicated it as a botanic garden and appointed Charles Fraser its first superintendent. The area thus dedicated is now known as the Middle Garden. In 1817 a large Norfolk Island pine, now known as the

'wishing tree,' was shifted from the Phillip-street garden to its present position. Fraser, who had been dignified with the title 'colonial botanist,' was not satisfied with the soil, and persuaded Macquarie to clear and fence 15 acres at Double Bay; but Brisbane cancelled this arrangement, added five acres to the Farm Cove site, and by 1825 had introduced nearly 3000 new specimens of food-plants and fruit-trees. The colonial office now began to take an interest in the garden, and demanded half-yearly reports including 'an accurate description of the Plants and Vegetables, which are peculiar to the Climate of New South Wales, as well as those, peculiar to other Countries, which are susceptible of cultivation to any useful purpose, if introduced into the Colony;' the botanist's salary, however, was left at seven shillings a day, and out of that he had to pay travelling expenses and the cost of sending seeds, etc., to England. This was no negligible expense, for in 1830 Fraser reported that he had sent seeds and plants to all parts of the world, including 1800 specimens to Glasgow for Professor Hooker.

Fraser died in 1831, and was succeeded by Richard Cunningham (q.v.), under whom the Lower Garden was laid out. When he was killed by blacks in 1835, his brother Allan (q.v.) took his place; during intervals between the death of one botanist and the arrival from England of another, John McLean (1831-3) and James Anderson (1835-7) looked after the garden. Allan Cunningham on appointment found that the establishment was still used for purposes unbefitting a botanic garden—e.g. he was asked to cultivate vegetables for the supply of high officials' tables—and lost little time in resigning his position; the circumstances are detailed in the article under his name. In 1837 a collection of plants was sent to Captain Lonsdale to stock the first government garden at Melbourne; almost at the same time another collection was sent to the newly-formed province of South Australia. Allan Cunningham was succeeded by James Anderson, who died on 24 April 1842; his successor, William Nasmyth Robertson, died in July 1844, James Kidd acted as temporary superintendent, and John Carne Bidwill (q.v.) was appointed on 1 September 1847, with the title of director and government botanist. Through some confusion, the home government also made an appointment, and Charles Moore arrived in Sydney on 14 January 1848 to take up the position, Bidwill receiving an appointment as commissioner of crown lands for the Wide Bay district. Feeling ran so high regarding the dual appointment that Stuart Donaldson, with the idea of starving Moore out, moved the reduction of the annual vote to £150; in this he failed, as well as in his later endeavour to have the gardens cut up and sold in allotments. Moore, who remained in office for nearly half a century, remodelled the greater part of the gardens, and under his supervision in 1869-70 the harbour frontage was reclaimed and the semi-circular stone wall erected. Superannuated in 1896, he was succeeded by J. H. Maiden, who resigned in 1924. The present curator is Dr. Darnell Smith.

The gardens now occupy an area of about 190 acres; the national herbarium (adjoining the curator's residence) erected under Moore, and greatly enlarged under Maiden, contains a large collection of botanical specimens and a fine botanical library. From a nursery attached to the gardens 153,000 plants and trees were distributed to State schools and public bodies during 1924.

BRISBANE.—In 1828 Charles Fraser, colonial botanist of New South Wales, was directed by Governor Darling to visit Moreton Bay and 'establish a public Garden at Brisbane Town.' Accompanied by Allan Cunningham, he arrived at Brisbane on 1 July 1828, and on the 3rd determined the boundaries of a garden containing 42 acres on the north bank of the river. James Backhouse in 1836 describes this garden as '22 acres of Government-garden for the growth of sweet potatoes, pumpkins, cabbages and other vegetables for the prisoners.' Up to 1855 the area was under military control, but in that year Walter Hill was made director of the botanic gardens with R. R. Mackenzie (q.v.) as chairman of the controlling committee. Hill was an ardent collector of the indigenous flora, as well as being keenly interested in exotic tropical and subtropical vegetation; he therefore made the gardens of unique interest by successfully filling them with flowering trees and shrubs, including many collected from the rich Queensland scrubs. In the early seventies an attempt was made to destroy his work by extending the business part of the city across the garden area, but this vandalism was fortunately averted. When Hill retired in 1881, F. M. Bailey (q.v.) was appointed colonial botanist and James Pink head gardener; Pink retired in 1886 and A. M. Cowan took charge until 1889, when P. McMahon was appointed curator. The great flood of 1893 swept across the peninsula on which the gardens are situated, damaged the bunya avenue and all the lower part of the grounds, and stranded a gunboat and a coasting steamer in the middle of the gardens. A second flood, 14 days later, carried the vessels back to the river. In 1905 J. F. Bailey became director, and in 1915 succeeded his father as government botanist; but in 1917, when he took the directorship of the Adelaide botanic garden, his nephew C. T. White was appointed government botanist, and E. W. Bick curator of the Brisbane gardens. The gardens now have an area of approximately 50 acres, a portion of the former government house domain having been added to them in 1916.

MELBOURNE.—Gipps having approved the establishment of a 'public domain for the purpose of rearing and cultivating indigenous and exotic plants,' Lonsdale in 1841 ordered Robert Hoddle, then surveyor-in-charge, to mark off a block of 50 acres on Batman's Hill and the adjoining river-bank. Of this order, as of many given by Lonsdale, nothing came; but several other sites were suggested, and in 1845 Latrobe chose the slopes of a gully leading down to the Yarra near the grounds of government house. Here John Arthur, the first superintendent (who was given that post on 1 March 1846), fenced in a 5-acre paddock and laid it out in flower-beds and plantations. Both he (1846-9) and John Dallachy (1849-57) paid attention to the introduction of exotic plants, and allowed the gardens to be used for horticultural shows. In 1857 a new office was created; Dr. Ferdinand Mueller (q.v.) was made director of the gardens, and at once began to develop their resources and their usefulness. He established close relations with similar scientific institutions all over the world, effected important exchanges of plants, re-arranged and much extended the grounds, and paid particular attention to the native vegetation. He also devoted part of the area to beds showing a scientific arrangement

of plants in their natural orders, etc., and established a 'national herbarium' which has become the most complete extant collection of Australian dried plants. In 1873 he retired in order to devote himself entirely to his work as government botanist, the directorship was abolished, and William Robert Guilfoyle became curator. He during his term (1873-1909) extended the gardens by over 30 acres and increased the number of species represented from 2500 to 14,000. The deepening and straightening of the course of the Yarra allowed an extension of the garden area which took in the old river-channel and added it to the existing lake, making 83 acres of garden and 10 acres of lake. A very complete re-arrangement followed, which has made the gardens probably the best example of landscape gardening in Australia. They now include a museum of botany (containing the herbarium), a 'classification pavilion' in which plants are arranged on Bentham and Hooker's system, and an 'Australian Plantation' of indigenous trees and shrubs. On Guilfoyle's retirement in December 1909 John Cronin became curator.

HOBART.—On 14 October 1843 a meeting held at government house under the presidency of Eardley-Wilmot formed itself into the Horticultural and Botanical Society of Van Diemen's Land. It was the governor's reply to the recalcitrance of the older Tasmanian Society (see ROYAL SOCIETIES) which he had wished to broaden. To his new creation—which in 1844 became the Royal Society of Van Diemen's Land for Horticulture, Botany, and the Advancement of Science—he entrusted the larger part of government house grounds, with a grant of £400 per annum for their maintenance and a good supply of convict labour. The first superintendent, F. W. Newman (1845-59), established a system of exchanges with other Australian gardens and gave much attention to the breeding of wheats suitable for the Tasmanian climate. The second, Francis Abbott (1859-1903), greatly enlarged the grounds, and extended the system of exchanges to gardens all over the world. During his term, in 1885, the gardens and the Tasmanian museum (see MUSEUMS) were placed under a board of trustees and given an income of £800 a year (increased at a later date to £1300), which they were at liberty to supplement by the sale of plants and flowers. At Abbott's death in November 1903 Alexander Morton, then curator of the museum, was made director of the museum and gardens (1904-8), and was succeeded by Robert Hall (1909-11). On Hall's retirement in July 1911 John Wardman was appointed superintendent.

ADELAIDE.—In 1855 a botanic garden committee was formed, a site containing about 40 acres was selected on the south bank of the Torrens, and George Francis, F.L.S., was appointed superintendent. The garden was thrown open to the public in 1857, and the first catalogue of plants published in 1859. In 1860, at the suggestion of Dr. Ferdinand Mueller, a valuable collection of Kangaroo Island plants was made for the garden by F. G. Waterhouse. In 1865 Francis retired, and was succeeded (as director) by Richard Schomburgk (q.v.), during whose term the garden was enlarged and its usefulness to the State much increased. The cultivation of trees suitable for railway construction and other public purposes was begun on a large scale in 1871, a museum of economic botany was built and furnished with a herbarium, and the importation, acclimatization, and distribution of useful exotic plants was developed with excellent results. After Schomburgk's death in 1890 Maurice William Holtze, F.L.S., Ph.D., who had since 1873 been curator of the garden at Port Darwin, took over the directorship. He retired in 1917, and was succeeded by John Frederick Bailey, son of Frederick Manson Bailey (q.v.). The present botanic garden (including an adjoining botanic park under the same management) comprises an area of about 105 acres, controlled by a board of governors appointed by the State government. It includes a 'class ground' on which plants are arranged in their natural orders, and a house specially built for the *Victoria regia* water-lily (discovered in Guiana by Schomburgk's brother). At Mylor near Adelaide is a 'type orchard' containing specimens of practically all the fruit-trees adaptable to the local climate.

PERTH.—Perth has no botanical gardens in the strict sense of the term. Stirling Square, adjoining the government house domain, was set aside in 1829 for the purpose, and some endeavour was made by James Drummond (q.v.), the first government botanist, to bring it into order. It has, however, become rather a small park than a botanic garden, though some of the plants contained in it have been named. In King's Park a large area is retained in its natural state for the purpose of exhibiting the native flora. Since James Drummond's time there has been no government botanist charged with the management of the government gardens. Baron von Mueller acted as consulting botanist to the colony until his death in 1890, and Drs. Morrison and Cleland afterwards occupied a similar position—but their real work was that of botanists and vegetable pathologists to the department of agriculture.

Botany. In the *Flora Australiensis* of Bentham and Mueller (1863-78) 7837 species were described. In 1889 von Mueller, in his *Systematic Census of Australian Plants*, gave the number of vascular species as 8909, comprised in 149 families and 1394 genera. From this total must be deducted 92 species peculiar to Lord Howe and Norfolk Islands, so that the true total of known Australian plants at that date was 8817; as the author of this article has record of 1856 additional species since the date of von Mueller's second *Census*, it is undoubtedly an understatement to put the number of Australian phanerogams and vascular cryptogams at 10,673. The following estimate of described species in each State has been compiled from the work of the various government botanists:—Queensland, 4480; Western Australia, 3900; New South Wales, 3600; Northern Territory, 2050; Victoria, 2000; South Australia, 1985; and Tasmania, 1210. Von Mueller stated that of his total of 8909 species 7501 are endemic, and of the remainder (1338, or 15.1 per cent) there are found in Europe 160, Asia 1032, Africa 515, America 315, New Zealand 291, and Polynesia 558; these figures have not been brought up to date.

Approximately speaking, the 12 largest families of Australian plants are as follows:—Leguminosae (1276 species), Myrtaceae (816), Proteaceae (667), Compositae (635), Orchidaceae (439), Gramineae (433), Cyperaceae (421), Epacridaceae (301), Goodeniaceae (294), Filices (255), Euphorbiaceae (251), Rutaceae (232). The largest genera, with their approximate number of species, are as follows:—*Acacia* (412), *Euca-*

lyptus (230), *Grevillea* (193), *Styphelia* (193), *Eriostemon* (193), *Melaleuca* (112), *Candollea* or *Stylidium* (112), *Goodenia* (112), *Hakea* (107), *Hibbertia* (104), *Pultenaea* (93), *Eremophila* (91), *Schoenus* (77), *Pimelia* (76), *Ptilotus* (76), *Panicum* (75), *Boronia* (72), *Cyperus* (72), *Aster* (71), *Helichrysum* (70), *Scaevola* (68), *Baeckea* (66), *Daviesia* (64), *Cryptandra* (63), *Drosera* (62), *Persoonia* (62), *Ficus* (62).

Three types of country influence the vegetation —(*a*) the forest, (*b*) the bush, whether scrub or brush, (*c*) the so-called 'desert' lands. The term 'scrub' is in Queensland applied to (*b*); in New South Wales it is applied rather to the comparatively sparse vegetation of the more sterile sandstone and granite areas; but it is also used to denote open forest, in which the species are as a rule more gregarious than those of the 'brush.'

Brush corresponds to the Indian jungle, and is applied to areas of sheltered, well-watered rich soil (chiefly in the coast-belt and tablelands of eastern Australia) which support rich arboreal vegetation, creepers and climbers of various kinds and shrubby undergrowth; the tree-vegetation is most varied in character (e.g. Meliaceae, Sapindaceae, Saxifragaceae, Cunoniaceae, Lauraceae, Monimiaceae, Coniferae and Taxaceae), but rarely includes eucalypts. In brush forests the buttress-stem—often of considerable size—is of frequent occurrence. These buttresses are thin, nearly vertical, almost like stalls in a stable. They are common in figs, the yellow carabeen (*Sloanea*), booyong (*Tarrietia*), red cedar, shebeech (*Cryptocarya*), marara (*Weinmannia*) and many others. Extending sometimes in fantastic shapes along the ground or—as in the yellow carabeen—so delicate as to be only an inch thick where they enter the ground, they form natural struts, essential to the stability of the long trunks that run up towards the light. Lianes are not unusual in the brushes—generally the stems of *Vitis* (q.v.) from which drinking water can be obtained.

Much of the country marked as 'desert' in the old maps is not desert in the strict sense, since it sustains a more or less sparse vegetation, including trees, while immediately after rain innumerable plants carpet the country-side with many-coloured species of *Helipterum* and *Helichrysum*, pink and purple *Ptilotus*, or various species of Salsolaceae and Goodeniaceae. The riverless areas of central Australia support an interesting xerophytic vegetation, and strips throughout the so-called desert are really pastoral country, supporting both grass and edible shrubs (see GRASSES and FODDER-PLANTS), while year by year the wheat-line advances into this region. The permanent plants of the drier lands depend upon subterranean water, often of small quantity and of local occurrence, besides the vast artesian accumulations. In Western Australia local supplies known as 'soaks' form oases round which there is a specially interesting vegetation.

The vegetation over vast areas of Australia knows only two seasons, the dry and the rainy. The rainy season may last only a few days in the year, or may be (more usually) intercalated with dry periods. After these showers the surface of the ground is changed, as if by magic; young plants cover it over large areas with bright carpets, quickly mature, develop seeds—and disappear, until the wet period of their life-cycle arrives with further rain.

The adaptation to environment of Australian desert plants, particularly those of Western Australia, has been ably treated by S. le M. Moore. Henslow quotes Volkens as stating that certain xerophilous plants, which are covered with a resinous substance that prevents a too energetic transpiration, are peculiar to the southern hemisphere. Examples of this are *Beyeria viscosa*, *Eucryphia Billardieri* (the Pinkwood of Tasmania), various species of *Dodonaea* and *Acacia*; moreover the roots of various grasses, and the young shoots of *Angophora* and of the Corymbosae section of eucalypts are protected by a covering that contains caoutchouc. The blanket-plants (*Lachnostachys*) of Western Australia are especially woolly, as are the allied genera *Newcastlia* and *Dicrastylis*. Many composites and malvaceous plants are very hirsute, these non-conducting coverings tending to hinder transpiration.

Instances of aphylly (plants without true leaves) are numerous: e.g. native cherry (*Exocarpus*), cypress pine (*Callitris*), she-oak (*Casuarina*), *Apophyllum anomalum*, *Tetratheca juncea*, *Comesperma* spp., *Daviesia alata*, *Sphaerolobium vimineum*, *Viminaria denudata*, *Amperoea spartioides*, and many others. There are also many succulent plants among the Zygophyllaceae, Portulaceae, Ficoideae, Crassulaceae, Salsolaceae, Euphorbiaceae and Asclepiadaceae. Some plants have water-storing cells in stems, or in roots, or in both; notable examples are the kurrajong, and the bottle-tree, which ludicrously resembles a gigantic lemonade bottle. In the north-west the Gouty Stem (*Adansonia Gregorii*) is a feature of the landscape, while aborigines in dry country obtain drinking-water from the roots of certain mallees (dwarf eucalypts), particularly *E. incrassata*, *E. dumosa* and *E. oleosa* as well as from *Hakea leucoptera* and *Casuarina Decaisneana*.

Origin of the Australian Flora.—Regarding the original Australian element, Wallace in *Island Life* observes that south-western Australia is the remnant of a more extensive and more isolated portion of the continent in which the peculiar Australian flora was principally developed. 'The existence there' he says, 'of a very large area of granite—800 miles in length by nearly 500 in maximum width, with detached masses 200 miles to the north and 500 miles to the east—indicates such an extension; for these granitic masses were certainly once buried under piles of stratified rock, since denuded, and then formed the nucleus of the old Western Australian continent . . . . While this rich and peculiar flora was in progress of formation, the eastern portion of the continent must either have been widely separated from the western or had perhaps not yet risen from the ocean.' In Cretaceous times, and far into the Tertiary, there was no Australian continent in existence; in its place were a large, almost wholly ex-tropical western island, a long and narrow eastern island extending from Cape York to a point south of Tasmania, and between them a wide crescentic sea with smaller islands representing parts of the Northern Territory and western Queensland (see map in *Island Life*). In the Cretaceous period, as shown by Jensen (*Proceedings* of the Royal Society of Queensland) in an article based on David's maps, the sea extended over most of Queensland from Cape York southwards (the eastern ranges and coast excepted) and covered a considerable portion of northern South Australia and north-western New South Wales. Jensen remarks that the Cretaceous sea was probably connected at both ends with the ocean, forming the aqueous barrier postulated by Wallace. The disappearance of this Cretaceous

sea made possible an eastward migration of the hardy plants (*Eucalyptus*, Proteaceae, etc.), which had developed on the barren soils of Western Australia; encountering on the eastern land area an Indo-Malaysian type of flora, they either expelled or subdued it. Jensen submits evidence from the fossil leaves of the older 'deep leads' and the trachytic tuffs of the Warrumbungle Range to show that the plants thus expelled were largely Lauraceae.

Tate in 1888 divided the Australian endemic flora into three types—(1) Euronotian, occupying the NE. and SE. coastal areas, its internal boundary coinciding with the rainfall limits of 25-50 inches per annum—the typical flora of this section is dominant in the southern and eastern parts of the continent; (2) Autochthonian, restricted to the SW. corner of the continent, its internal boundary coinciding with the same rainfall limit in this part; (3) Eremian, occupying a large stretch of country that extends from Lake Eyre right across the continent to the shores of Western Australia, and over which the average rainfall is above 10 inches per annum. Besides this endemic flora there is what he styles an 'immigrant' flora with two constituents:—(*a*) Oriental, dominant in the littoral tracts, but mixed there with typical Australian genera; (*b*) Andean, restricted for the most part to the highlands of New South Wales, Victoria and Tasmania; with this he includes species characteristic of north temperate regions. Hedley and Baldwin Spencer have—on zoological grounds—suggested modifications of Tate's proposals; but the point of most importance is the demonstration of the fact that for a long period of time the eastern and western parts of the continent were separated by an impassable barrier of some description; and most authors agree that the separation took place in Cretaceous times. According to Tate the Eremian flora was developed in central Australia in Pliocene times from Autochthonian and Euronotian elements, and was largely modified by Oriental immigrants.

It was for some time held that the European Tertiary flora contained *Alnus, Betula, Quercus, Sequoia, Acer, Pinus* and other genera peculiar to the northern hemisphere, together with *Casuarina, Grevillea, Banksia, Dryandra, Leptomeria, Eucalyptus* and other genera peculiar to the southern hemisphere. Von Ettingshausen recorded *Eucalyptus* and *Metrosideros* in the Eocene beds of Sheppey, England; *Pimelia, Leptomeria* and four genera of Proteaceae were recorded by Heer in the Miocene of Switzerland. Ettingshausen believed he had found 55 Australian forms in the Eocene beds of Haering in Bohemia; but Hooker considered these determinations worthless, and Bentham disapproved of similar identifications by Heer and Unger. Ettingshausen also records many European forms in the Tertiary of Australia; but Deane (*Proceedings* of the Linnean Society of New South Wales for 1897) firmly disputes the accuracy of certain of the determinations, and Hemsley in the *Challenger* reports says that, until more conclusive testimony is forthcoming of the former existence of Proteaceae, *Eucalyptus*, etc., in Europe, we cannot avoid the conviction that they originated in the south.

Botanical determinations and deductions built by some palaeo-botanists upon mere leaf-impressions are to be regretted. Except in the case of very characteristic material, botanists who deal with existing flora usually ask to be excused from determining a plant on a leaf only. Bentham states that the predominant portion of our vegetation appears to be strictly indigenous, and that the great mass of purely Australian species and endemic genera must have originated, or have been differentiated, in Australia, and never spread far out of it. The only exceptions observed by him are (*a*) a few Australian types (e.g. *Eucalyptus*, Epacridaceae, phyllodineous acacias, etc.) which appear in Malaysia (especially in Timor, New Guinea, and Borneo) where they have established distinct, though in most cases, nearly representative species, sometimes, however, preserving absolute identity; and (*b*) a very few, chiefly annual or herbaceous, plants of various Australian genera which are found as far away as southern China, mostly in identical or very closely representative species. In Bentham's time, however, comparatively little was known of the Chinese flora; through the publication of Forbes and Hemsley's *Enumeration* and other works, we are now in a far better position to indicate the precise relationships of the Australian and Chinese floras. The flora of Malaysia is also now much more available to students.

According to Bentham, the principal flora that shows an ancient connection between Australia and other countries is the Indo-Australian. A number of genera whose main station is in tropical Asia extend more or less into tropical or eastern subtropical Australia, sometimes in identical, sometimes in more or less differentiated species. Those of coastal Queensland have generally an East Asiatic character. A few types belonging to Ceylon and India are more especially represented in Arnhem's Land, but scarcely any Indian forms are found westward of that peninsula. In his *Malay Archipelago* Wallace remarks that, when we consider the wonderful dissimilarity of the Papuan and Australian regions in all those physical conditions which were once supposed to determine the forms of life—Australia with its open plains, stony deserts, dried-up rivers and changeable temperate climate; Papua, with its luxuriant forests, uniformly hot, moist and evergreen—this great similarity in their productions is almost astounding, and unmistakably points to a common origin. He does not, however, note the fact that northern Queensland, east of the divide, may be described in terms precisely similar to those employed by him in regard to Papua.

The Austro-Malay element is common in the coastal brushes of Queensland and northern New South Wales. In 1892 above 2000 species of phanerogams were known from New Guinea; in 1911 nearly 3000 species had been described from that region, chiefly through botanical activity in the German possessions. The whole of New Guinea is a region of tropical forests, only occasionally interrupted by savannahs (grass-lands interspersed with trees). What Wallace says of Borneo—that an orang-utan could cross the island from tree to tree without putting his foot to the ground—applies fairly well to New Guinea. The chief savannahs are at the mouth of the Fly River, and the grasses there are chiefly composed of *Imperata arundinacea* (blady grass), *Themeda* (kangaroo grass), *Rottboellia, Andropogon, Apluda, Pennisetum*, etc., all tall grasses; while the interspersed trees are mainly specimens of *Eucalyptus* (*E. tereticornis, E. alba, E. clavigera, E. terminalis*) and other Myrtaceae, *Acacia* (*A. Simsii, A. holosericea* and another), and Proteaceae. The character of these Fly River savannahs is almost (or quite) identical with that of Cape York Peninsula, the northernmost point of which is only about 100 miles from the mouth of the Fly River; but this is the only part of New Guinea in which strong affinities

to the flora of Australia are shown. It seems strange that the Australian flora has not taken a greater possession of New Guinea; the types of its flora are South Asiatic, and Australian plants are rare there except in the Fly River savannahs. The data, however, are incomplete, and this statement cannot be made without reservation.

By far the majority of Papuan genera are Malaysian; but it would be wrong to consider the flora of New Guinea identical with that of Malaysia, the number of endemic genera and species being too great. Epiphytic rhododendrons are common in high elevations in what used to be German New Guinea, connecting the flora with that of the Himalaya. A rhododendron is also found on the Bellenden-Ker ranges in northern Queensland. Warburg states that rhododendrons —mostly beautifully large-flowered species—are common on the Papuan mountain ranges at high elevations, and that two indigenous Coniferae (*Phyllocladus hypophylla* and *Libocedrus papuana*) are closely allied to species he met with in mountain regions of Borneo. These genera are also found in New Zealand, and *Phyllocladus* occurs in Tasmania. Several species of *Quercus* (oak) are found at high altitudes in New Guinea, providing another link with the Himalaya. No *Quercus* has yet been found in Australia. As far as we know the floras of New Guinea, New Zealand and the Melanesian islands, endemism is greatest in the first-named region, but New Caledonia may be found to equal it when that flora is better known.

Agapetes and *Dracophyllum* also occur on the Bellenden-Ker range; the former genus is represented by about 30 species, chiefly from the southern Himalaya and a small number from Fiji, Borneo, and New Guinea; the two Papuan species have been found on the Owen Stanley range. *Dracophyllum* is interesting as connecting the Bellenden-Ker flora with the Antarctic, the genus is common in the Antarctic islands and in Tasmania, while one species is found in New South Wales, Lord Howe Island, New Zealand and New Caledonia, chiefly in mountainous regions. It is not found, so far as the writer knows, in New Guinea, Malaysia, or Asia. Bentham remarks that an exchange, limited in extent, has evidently taken place between north-east Australia and New Caledonia and other islands of the South Pacific is plants not strictly maritime. More Australian types appear to be represented in New Caledonia than New Caledonian types in Australia. Hooker, following Forster, used the expression 'Antarctic plants of Australia,' not because they inhabit land beyond the polar circle, but because botanically, in relation to the south temperate flora, they represent the arctic flora. He adds that they might almost be called alpine plants, for many found at sea-level in the so-called Antarctic islands also ascend the mountains of more genial latitudes. Bentham also notes the connection of the alpine flora of Tasmania, Victoria and New South Wales with the general southern extra-tropical and mountain region that extends through New Zealand to the southern end of the American continent, and thence up to the Andes. Many Australian species of this type are identical with, or closely representative of New Zealand species, and some have a much wider range. It is probably through this connection that a few species belonging to the temperate floras of the northern hemisphere have evidently, in very remote times, become represented in Australia. The tabular view of the distribution of the phanerogams of the islands south of New Zealand given by T. F. Cheeseman in *Sub-antarctic Islands of New Zealand*, together with his notes on the affinities of the flora, are most suggestive; see also valuable botanical contributions by Dr. L. Cockayne, R. M. Laing and D. Petrie in the same work. These antarctic representatives are chiefly to be found in Tasmania, which, moreover, has a surprising number of plants in common with the Australian Alps of Victoria and New South Wales. The antarctic genera represented in northern New South Wales (e.g. *Nothofagus*) and Queensland (e.g. *Dracophyllum*) are much fewer, as are also those of Kangaroo Island and South Australia.

The flora of South Africa and Australia have a great many species in common, but hardly any that are confined to the two regions; all, or nearly all, the species found both in South Africa and in Australia are cosmopolitan plants, or plants of wide geographical distribution. Even the genera common to the two countries are not numerous. Still, there are many affinities between them; but the connection that once probably existed, via the Antarctic, must have been broken so long ago that their common ancestors had time to develop into distinct species and genera. Australia, for instance, has 34 genera of Proteaceae, mostly endemic, though some are also found in New Zealand, New Caledonia and Malaysia; South Africa has 11 genera of this family, mostly endemic; and not a single genus of Proteaceae is common to Australia and South Africa. Yet, as Hooker points out, by far the greater number of the known species of Proteaceae are confined to these two countries. Of our Australian Restiaceae, the genera *Restio*, *Leptocarpus* and *Hypolaena* are common to both.

The enormous time that must have elapsed since the separation of the two floras by geologic changes is still better indicated by the Epacridaceae (q.v.) and Ericaceae. The common ancestors of the two families probably lived in both continents. As in the Proteaceae, the descendants developed along different lines; for some reason genera with anthers opening in terminal pores (Ericaceae) prevailed in South Africa, and genera with anthers opening in parallel slits (Epacridaceae) prevailed in Australia.

With regard to the Compositae Bentham says that, setting aside the cosmopolitan genera *Senecio* and *Gnaphalium*, the following genera are common to the two regions:—

	NO. OF SPECIES.	
	Australian	South African.
Brachycome	41	1
Helipterum	53	12
Helichrysum	70	137
Cassinia	13	1
Athrixia	7	6
Cotula	8	22

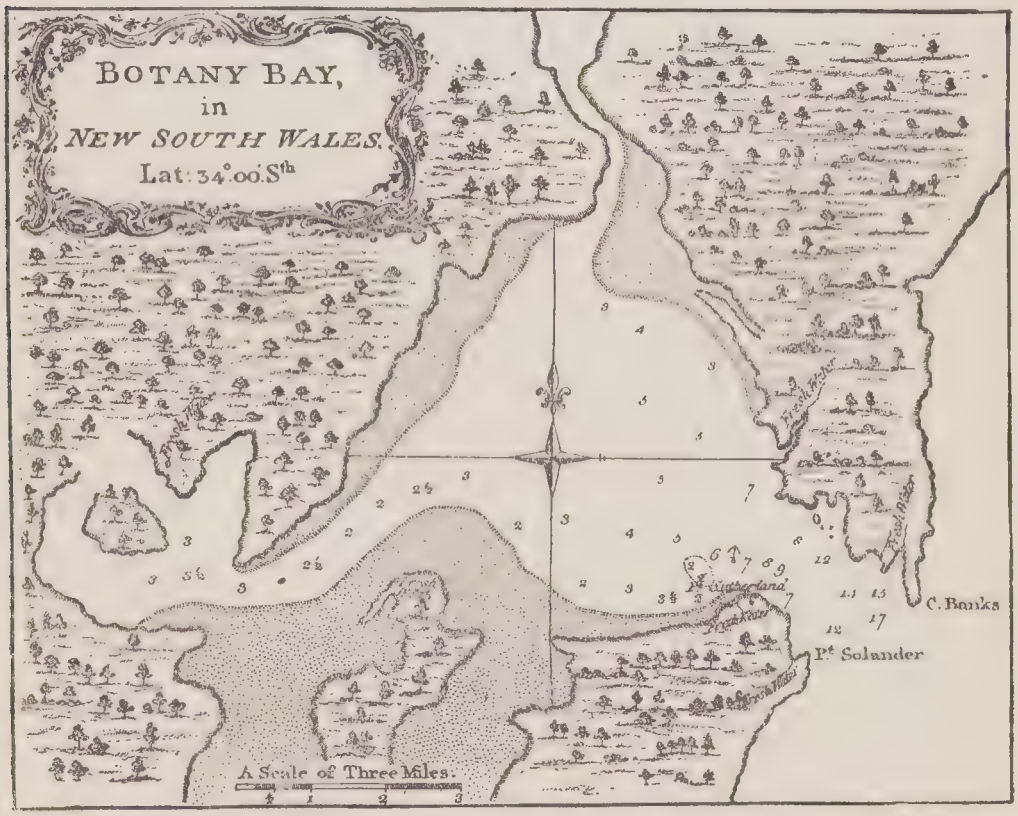
Bolus and Woolley-Dod point out that the three families Thymelaceae, Haemodoraceae, and Droseraceae are most abundant in Australia and, in the second place, in South Africa. Another point of likeness is seen in the remarkable deficiency in both countries of the otherwise widely diffused families Rubiaceae, Lauraceae, Araceae. Hooker, who first discussed the subject, suggested that the flora of Australia and south-western Africa might have had a common origin from ancestors inhabiting a vast Antarctic continent, of which the greater part has been submerged. He thought western Australia was connected with the Cape region by land at a time when it was severed from eastern Australia. But Moseley asks pertinently why marsupials are not found at the Cape, although they do occur in the Great Oolite of England. It would almost

seem that they must have occurred at the Cape, and have died out—unless Proteaceae and Restiaceae are very much older than marsupials, in which case they would be very old indeed.

Australia has three grand types of flora—the brilliant inflorescences of the sandy plains of Western Australia, the luxuriant vegetation of eastern Australia, and the alpine flora of Tasmania. South Australia, the north-west of Victoria and the vast western plains of New South Wales and Queensland approximate to the botanical conditions of the western State. Many Tasmanian or allied plants extend to south-eastern Australia generally. The rain-forests of western Tasmania are unique, and on the mainland are most closely approached by those of the Cape Otway district of Victoria. Bentham remarks that maritime plants, ranging at least from the Mascarene Islands to those of the Pacific, are also to be found on the Australian coasts, mostly in identical species, with the addition of a few representative species. The following families are entirely or almost entirely confined to Australia —Tremandreae, Stackhousiaceae, Candolleaceae, Goodeniaceae, Casuarinaceae, Philydraceae, together with the phyllodineous acacias (which form an enormous majority of the genus) and *Eucalyptus*.

It is sometimes stated that the Australian flora is of a primitive character, but Moore strongly asserts that this is the result of bias imparted by the zoological data. 'In what respect, it may be asked, is the flora of Australia less highly specialized? Are not most of the great natural orders strong constituents of it? Trees, some of them of gigantic size, shrubs, undershrubs and herbs, parasites and saprophytes, climbing and carnivorous species, flowers adapted to profit by the visits of insects, and sometimes provided with a complex mechanism to insure such profit—all these are met with in Australia. In addition, the adaptability to the dry climate is wonderful, and in this respect, taking into account the variety of ways in which the destructive effects of a scorching sun and parched soil are guarded against, the Australian flora is without a parallel the world over. And if these be not evidences of high specialization, it is difficult to know where one must look for such.'

The work of the principal botanists who have paid special attention to the Australian flora is discussed under their names. See BENNETT, GEORGE; BIDWILL, J. C.; BROWN, ROBERT; CALEY, GEORGE; CUNNINGHAM, ALLAN; CUNNINGHAM, RICHARD; DRUMMOND, JAMES; GUNN, R. C.; MACGILLIVRAY, J.; MUELLER, FERDINAND VON; SOLANDER, D. C.; WOODS, J. E. T.; WOOLLS, WILLIAM. The work of W. S. Macleay is noticed under MACLEAY, ALEXANDER. For references in this article to books or articles not already specified see Bentham's preface to his *Flora Australiensis* and article in the *Journal* of the Linnean Society, vol. xiii; Ettingshausen's *Die Genetische Gliederung der Flora Australiens*, and his *Beiträge zur Kenntniss der Teritärflora Australiens* (translated in the *Memoirs* of the Geological Survey of New South Wales); Hedley in the *Proceedings* of the Australasian Association for the Advancement of Science, vol. v; Hooker's *Flora Tasmaniae*; Spencer Moore in *Natural Science*, vol. xv; Moseley's *Notes by a Naturalist*; Baldwin Spencer's *Report on the Work of the Horn Scientific Expedition*; Tate in the *Proceedings* of the A.A.A.S., vol. i; and Woolley-Dod in the *Transactions* of the South Africa Philosophical Society, vol. xiv.



Botany Bay (from Atlas illustrating Cook's Voyage).

Botany Bay, an inlet on the eastern coast of Australia, five miles south of Port Jackson. The peninsulas forming its entrance (La Perouse and Kurnell) are government reserves; the rest of its shore-line is occupied by suburbs of Sydney. Cook's River flows into its north-western corner, and George's River into the south-western.

It was in Botany Bay, just within the entrance of the southern (Kurnell) peninsula, that James Cook made his first landing on Australian soil. The *Endeavour* lay off the peninsula from 29 April to 7 May, and Cook and Banks explored the shores of the bay and the inflowing streams as fully as was possible in the time. The name first given to it, according to Cook's log and Banks's journal, was 'Sting-Ray Harbour' or 'Stingrays Bay:' the name 'Botany Bay' first appeared in Hawkesworth's account of Cook's voyage, and it was for long believed that Hawkesworth himself had invented it. But the evidence, discovered later, of Banks's autograph journal cast a doubt on this belief; and the discovery in 1921 of Cook's autograph journal (see COOK, JAMES) has settled the matter once for all. In it the words 'Sting Rays Harbour,' which were first written, are deleted in favour of 'Botanist Bay,' and this again is corrected to 'Botany Bay;' the reason assigned for the change is 'the great quantity of New Plants &ca. Mr. Banks and Dr. Solander collected in this place.'

The alterations, which are in Cook's own handwriting, indicate that the change of name was made by Cook himself; but the Banks journal shows that it was not made until some time after the *Endeavour* had left the Australian coast, since Banks in his summary of Australian conditions used the first name. It is probable that during the long homeward voyage Cook revised his journal—possibly he read it to Banks—and in two revisions arrived at the more euphonious name, but did not trouble to alter the log, or to mention the change to his officers.

Bot-flies, insects of the family Oestridae whose larvae (the 'bots') infest the stomachs or other internal organs of several domestic animals. The only known endemic bot-fly is one (found only in the larval form) that infests the throats of kangaroos in Queensland and north-western Australia. But several of the more serious pests of stock have been introduced, and two at least—the horse-bot and the sheep-bot—annually cause the deaths of many animals. The ox-bot (*Hypoderma bovis*) has so far not become established in Australia, but has often been seen on imported cattle in quarantine.

The Horse Bot-fly (*Gastrophilus equi*) probably attacks all horses running free in Australia; its eggs, usually laid on the hairs about the chin and fetlocks, are a very common sight, as many remain on the hairs after the larvae have hatched. On being licked into the mouth or taken with food they pass into the stomach, to the walls of which they fasten themselves, frequently in the region of the pylorus; or they may become fixed to parts of the intestines or rectum. Here they remain for several months, till ready to mature, when they pass out with the dung and burrow into the ground to pupate. When but a few are in the stomach, little harm results; but they are frequently so abundant as to occupy all the available space, so that the horse rapidly loses condition and dies. The mature flies have a terrifying effect upon horses, which gallop about or become restive when they hear them. To minimise their attacks a common plan is to singe the hairs on which the eggs are laid, or to rub them with an oily rag; once in the stomach, little can be done, as the maggots are capable of withstanding most drugs that can be safely administered.

The Sheep Bot-fly (*Oestrus ovis*) occurs with sheep in several parts of Australia, and it is probably only a matter of time before all the States will be affected. Maggots (rarely eggs) are laid on the sheep's nose, and at once work their way up the nasal passage to the frontal sinus, where they usually remain till ready to mature; they then pass down the nostrils and drop to the ground. Occasionally they work their way into the brain, through openings in the ethmoid bone. The ceaseless irritation caused by these maggots, when in numbers, frequently results in death; but before dying the sheep will often run about in an aimless way, butting into everything in its way and frequently sneezing.

The Camel Bot-fly (*Cephalomyia maculata*) at one time or another attacks all camels in Australia. As a string of these animals goes along, one or other of them is frequently seen to stop and sneeze violently, discharging a maggot in the process.

R.J.T.

Bottle-brush. See BANKSIA and CALLISTEMON.

Bottle-tree (*Brachychiton rupestris*), known also as Gouty Stem, owing to the shape of the swollen trunk, which is contracted at the base and apex, is a large tree confined to Queensland and northern Australia, with leaves entire (or divided into 5-9 lobes) growing on the sterile branches. The stem abounds in a mucilaginous substance, resembling tragacanth, which is wholesome and nutritious and used as a food by the aborigines. The gummy exudation is remarkably like paraffin in appearance. The swollen trunk is a reservoir of water. The natives obtain an abundant supply of the sweet mucilaginous juice by cutting holes in the trunk. Specimens are sometimes 50 to 60 feet high, with a diameter where the trunk is thickest of 6 or 7 feet.

Boucaut, SIR JAMES PENN (1831-1916), son of Captain Ray Boucaut of the East India Company's service, was born near Falmouth in Cornwall on 29 October 1831, and educated locally. In 1846 he accompanied his father to South Australia, and after a few years on a station turned to the study of the law and was called to the local bar in 1855. Entering politics, he became successively member for Adelaide (1861-2), West Adelaide (1865-8), the Burra (1868-70), West Torrens (1871-5), and Encounter Bay (1875-8), and was three times attorney-general and three times premier (1866-7, 1875-6, 1877-8). During his second premiership he initiated a far-reaching public works policy. In 1878 he left politics for the bench, taking a supreme court judgeship, which he relinquished in 1905. In this period of his life he was twice administrator of the government, several times deputy-governor, and twice (1892 and 1897) acting chief justice. After his retirement he devoted himself to breeding pure Arab horses, and wrote a book on the subject—*The Arab, the Horse of the Future* (1905). He died on 1 February 1916.

Boucaut is particularly notable as a politician for two things—his refusal to borrow profusely without providing safeguards (an uncommon thing in the seventies), and his devotion to Australian rather than to local interests. He was one of the first advocates of inland railways con-

necting South Australia with the western districts of New South Wales, and eventually with Queensland. (K.C.M.G., 1898).

Bounty, MUTINY OF THE. Although this notorious event is in no way connected with the history of Australia, its discussion here seems sufficiently justified by the facts that (*a*) the officer against whom it was directed afterwards became governor of New South Wales, (*b*) Norfolk Island, a territory of the Commonwealth is populated with descendants of those Pitcairn Islanders whose existence is a direct result of the mutiny.

Several 18th century explorers of the South Seas having reported on the value of the breadfruit (*Artocarpus incisa*) as a food in hot climates, the West Indian planters petitioned George III to supply them with plants for acclimatization. In answer to this request the admiralty during 1787 fitted out H.M.S. *Bounty* (an armed transport of 215 tons) for the conveyance of a number of plants from Tahiti, and on the recommendation of Sir Joseph Banks gave the command to Lieutenant William Bligh. The crew—45 besides the commander—included John Fryer as master, Fletcher Christian as senior master's mate, four midshipmen, various petty officers, 23 able seamen and two gardeners. The *Bounty* sailed from Spithead on 23 December 1787, touched at Teneriffe, Simon's Bay, and Adventure Bay in Tasmania, reached Tahiti on 25 October 1788, and spent nearly five months loading plants in Matavai Bay. According to Bligh's narrative, all had so far gone well; according to all other witnesses at the subsequent court martial, there had been constant friction between the commanding officer and his subordinates. The *Bounty* left Tahiti on 4 April 1789. On the 28th, just as day was breaking, Bligh was rudely awakened by Fletcher Christian and three seamen, forced on deck at the points of their weapons, and with 18 others sent adrift in the ship's launch. Among the 18 who stood by Bligh were the master of the *Bounty*, the acting surgeon, botanist, gunner, boatswain, carpenter, one master's mate, two midshipmen, two quartermasters, and the sailmaker; with Christian stayed three midshipmen, the master-at-arms, six minor petty officers, and 14 sailors. The *Bounty* then trimmed sails and disappeared. In the launch (a boat 23 feet long, six feet nine inches in the beam, and two feet nine inches in depth) had been placed 32 lb. of pork, 150 lb. of biscuit, a 28-gallon cask of water, six quarts of rum, and six bottles of wine, besides canvas, twine, a few empty watercasks, and four cutlasses; Christian also gave Bligh his sextant and a book of nautical tables. Bligh found himself a few miles S. of Tofoa (one of the Friendly Islands) and decided to make for it, but after reaching it that evening and staying there until 2 May was driven away by a sudden attack of the natives, who killed one of the seamen.

When the *Bounty* left England the 'First Fleet' of transports for Botany Bay had been gone about seven months, and Bligh had no means of knowing whether the enterprise had been successful. He could not, therefore, count on obtaining help in that quarter. On the other hand, to settle down on a Pacific island, even if the natives permitted it, would minimize his chances of ever reaching England again. He therefore determined to make the north coast of New Holland and thence endeavour, by following Cook's route, to reach some European settlement in the Malay Archipelago.

On the 26th day of the boat-voyage breakers on the Barrier Reef were sighted, and two days later Bligh found a passage through the reef (now marked on the charts as Bligh's passage in 12° 51′ S. lat.) a little S. of Cook's Providential Channel. Inside the reef the party found smooth water and a resting-place on what is known as Restoration Island, about 500 yards offshore opposite Cape Weymouth. A week's voyaging along the coast took them to and through Torres Straits past Sunday Island, Wednesday Island, Shoal Cape and Booby Island; Koepang was reached on 15 June, 41 days after leaving Tofoa. During this time 18 men on very short rations in an open boat had voyaged about 3600 miles, encountering many storms and much rain, and at Koepang they were so cramped and weakened that they could scarcely crawl up the beach. Nelson the botanist died at Koepang of the effects of the voyage; when in a hired vessel they reached Batavia, Ledward (the acting surgeon) decided to remain there, and Elphinstone (master's mate) and two seamen, Linkletter and Hall, succumbed to fever. Bligh and the rest soon obtained a passage home, and reached England in March 1790.

The British government promptly fitted out the *Pandora* frigate (Captain Edward Edwards) to search for the mutineers. She took with her Hayward and Hallet, who had been with Bligh in the boat, and reached Matavai Bay on 23 March 1791. Before her anchor was down the midshipmen Stewart and Heywood, with a seaman named Coleman, came off in a canoe and surrendered, and a few hours later 12 others were made prisoners. They informed their captors that the *Bounty* under Christian's command had, after casting Bligh adrift, visited Tubuai in the Society group and then returned to Tahiti. Later on the mutineers had agreed to separate, and Christian—taking with him eight of the crew, three Tubuaians with their wives, three Tahitians with their wives and one infant girl, and ten other Tahitian women—had sailed with the *Bounty* to an unknown destination. Two of the mutineers who were left on Tahiti had been killed in a quarrel; others had built a small vessel, which they named the *Resolution*, in which to attempt the voyage to Batavia. Stewart had married a native woman. She died of grief soon after her husband was taken away in the *Pandora*, and her infant daughter, brought up by missionaries who subsequently landed on the island, survived until quite recent years.

The *Resolution*, manned by a small crew from the *Pandora*, was sent with one of the ship's boats to search the group; the boat was never afterwards heard of, and the *Resolution* not seen again until after an adventurous voyage she rejoined the *Pandora's* crew at Samarang. There she was sold, and afterwards purchased at Canton by Captain Broughton to assist him in surveying the coast of Tartary; during this part of her career she was the means of preserving the crew of H.M.S. *Providence*, when that ship was wrecked off Formosa in 1797. The *Pandora's* voyage was continued with her 14 prisoners confined in a wooden cell 11 feet by 18 (built on the quarter-deck for the purpose, and familiarly known as Pandora's Box), until on 28 August while working her way through Torres Straits in 11° 25′ S., she struck a reef and became a total wreck. (The ship's log, incorrectly, gave the latitude as 11° 20′ S.) The ship's company with the greatest difficulty managed

to save all but 29 of their number, among whom were four of the *Bounty* prisoners. In four boats the remaining 135 made their way to Timor, reached it on 19 September, and were ultimately brought to England. By a court martial assembled to deal with the 10 survivors of the *Bounty's* crew four were acquitted and the rest sentenced to death. Morrison (petty officer) and Heywood (midshipman) were both strongly recommended to mercy, the former because it was clearly established that he had done all in his power to prevent the mutiny; Muspratt (seaman) was at the last moment respited for the same reason. Heywood was a boy of 15 at the time of the mutiny, and it was clear that he had no knowledge of it until after the boat was cast off. Morrison afterwards rose to be a warrant officer, and was drowned in the *Blenheim* in 1807. He had kept a journal of the whole affair, which, borne out as it is by other evidence, is a reliable authority on the subject. Heywood was restored to his rank, and afterward became a post-captain and a distinguished officer in the service. The conduct of Edwards to his prisoners, both before and after the wreck of the *Pandora*, has been condemned as brutal by all writers, including officers in the service; Barrow, secretary to the admiralty, is one of the severest of his critics.

Nothing more was heard of the *Bounty* until in March 1809 Captain Folger of the American whaler *Topaz* reported that he had discovered on Pitcairn Island the last survivor of the mutiny with a small community of the mutineers' descendants. England was too busy with the war against Napoleon to attend to the report; but in September 1814 two frigates—the *Briton* and the *Tagus*, under Sir Thomas Staines and Captain Pipon—visited the island. Pitcairn had been lost sight of since its discovery in July 1767 by Carteret, who fixed its position wrongly. The visitors of 1814 received from the lips of John Adams (*alias* Smith), the surviving mutineer, an account of the happenings which there is no reason to doubt. Christian, made commander by consent of the rest, decided after leaving Tahiti to make for Pitcairn, and after some difficulty found the island and ran the ship ashore on a sandy beach. Taking all that was of value from her they made for themselves a comfortable home, planting food-stuffs and rearing pigs from stock brought in the ship. The quarrels that soon began ended in the death by violence of all the male natives and several whites, including Christian himself. Adams then took charge of the settlement, taught the people to lead decent lives, and died a respected man on 29 March 1829.

In the *True Briton* of 12 September 1796 a statement appeared to the effect that Christian was then living in South America. What purported to be a full account of the *Bounty's* cruise after the mutiny was also given as allegedly received by a correspondent from the lips of Christian himself (it should be noted that this account represents Christian as acquitting Bligh of all blame for the mutiny). Barrow states that about 1808-9 a rumour was prevalent that Christian had been seen in the neighbourhood of the Cumberland lakes, his former home; also that Heywood had seen Christian in Plymouth. It seems probable that this and similar statements were purely imaginative, and the *True Briton's* story may even have been invented in Bligh's interests.

Of the true causes of the mutiny nothing can be said with certainty. But it is certain (for no one except Bligh himself has ever denied it) that life aboard the *Bounty* was anything but pleasant; there were repeated floggings, and Bligh's language and conduct towards both officers and men were consistently offensive. Fryer the master, one of Bligh's staunchest supporters, gave evidence that Christian's last words before cutting the boat adrift included 'I have been in hell this last fortnight . . . . during the whole voyage I have been treated like a dog.' The contrast between life aboard under such conditions and the easy life of the stay at Tahiti would be sufficient inducement to many of the crew to join in a mutiny designed by officers with a more particular grievance. Barrow, himself a secretary to the admiralty, says explicitly that on the evidence taken at the court martial Bligh was responsible for what happened.

Bligh's side of the case is stated in his *Narrative of the Mutiny on board His Majesty's Ship 'Bounty'* (London, 1790), which however deals almost entirely with the boat-voyage. The original MS. of this book is in the Mitchell Library. Barrow's *Eventful History of the Mutiny and Piratical Seizure of H.M.S. 'Bounty'* (London, 1831) is probably the most impartial account of the transactions; Lady Belcher's *Mutineers of the 'Bounty'* is somewhat biassed by the fact that she was a step-daughter of Heywood, against whom Bligh used all his influence at the court martial. Hamilton's *Voyage Round the World in His Majesty's Frigate 'Pandora'* (Berwick, 1793) is the chief authority for that ship's doings. Judge McFarland of Sydney in 1884 published *The Mutiny in the 'Bounty,'* a highly judicial utterance; and Lord Byron's *The Island* and Becke & Jeffery's *The Mutineer* are fiction (in verse and prose respectively) based on the mutiny and its consequences. W. J.

Bourke, Sir Richard (1777-1855), born in Dublin on 4 May 1777 and educated at Westminster School and Oriel and Exeter Colleges, Oxford (B.A., 1798), was trained for the bar, but abandoned law to enter the army on 22 November 1798 (ensign, 1798; lieutenant and captain, 1799; major, 1808; colonel, 1814; major-general, 1821; lieutenant-general, 1837; general, 1851). After terms of service in Holland (1798-9) and South America (1806-7), he was in 1808 made assistant-quartermaster-general of Wellington's army in Portugal, and, knowing Spanish, became liaison officer with the Spanish army under Cuesta, but in 1809 for an unknown reason resigned his post and returned to England. In 1812 he went back to Spain in the same capacity as before, and controlled the issue of supplies to the army from Corunna until the war ended. From 1814 to 1825 his career is obscure, but in the latter year he was appointed lieutenant-governor of the eastern province of the Cape Colony (and in 1826-8 acting governor of the whole colony), where he had to deal with agricultural and press troubles very similar to those he at a later date encountered in New South Wales. His sympathetic treatment of the Kaffir tribes on the eastern border was resented by the Boer farmers of his province, and had a good deal to do with the 'great trek' of 1835. In November 1828 he returned to England, and with Lord Fitzwilliam edited in 1829 the *Letters* of Edmund Burke, who according to some authorities was his relative, and whom he had frequently visited at Beaconsfield in his youth. In 1831 he was chosen to succeed General Darling as governor of New South Wales, and reached Sydney on 2 December.

His term of office was much troubled, but important results were achieved and more important reforms devised and prepared for. The revolt of the emancipists (q.v.) against the long-continued rule of 'exclusive' officials, tolerated or sup-

ported by Brisbane and Darling, was at its height. Bourke attempted with a good deal of success to ignore both parties and to decide questions, as they came up, on their own merits; he thus provoked the enmity of the disappointed of both factions, but in the end removed the reasons for the existence of any such factions. He minimized the evils of the assignment system (q.v.) and substituted for it as a source of labour the introduction of free labourers from England. He passed a Church act which did away with many religious grievances, and was the nearest approach to religious equality that the colony achieved for many years. He initiated a system of civilian juries, on which emancipists might sit, for criminal trials. He abolished the system of land-grants, substituting sale of crown lands by public auction, and used the proceeds (so far as lay in his power) to pay the passages of the migrant labourers already mentioned. He completely freed the press, and even invited reporters to attend meetings of the council. He established the first savings-bank, encouraged the first mechanics' institute, and much improved the means of public education. Mitchell's explorations of 1835-6 owed a great deal to his encouragement, and the lasting nature of the Batman-Fawkner settlement on Port Phillip was largely due to his discreet handling of a very difficult situation. He also devised the 'squatting' system, whereby stockowners who were trespassing on the colony's lands beyond the bounds of settlement could obtain for a small annual fee a licence to go on trespassing; this device gave room for the growth of the valuable wool industry without disposing irrevocably of land that might some day have a much increased value. Besides all these actual achievements he managed by his influence, both in the colony and with the British authorities, to create an atmosphere of peaceful and humane progress in which social and political reforms throve, and which came to fruition under his successor. It is not suggested that he personally and alone was responsible for all the reforms just enumerated. Several of them were directly ordered by the British government, and others owed a good deal to the wisdom of local statesmen. But it was Bourke's tact and sympathy that ensured their successful adoption at a time when his official superior, Lord Aberdeen, used to declare that hot water was the favourite element of colonial mankind; a good many of them were initiated by himself; and the common sense of the colonists did not err in attributing to him, in an inscription on the base of his statue in the Sydney Domain, the credit for them all.

In 1837 Bourke found it necessary to suspend C. D. Riddell, the colonial treasurer, from his position in the executive council. Lord Glenelg, the then colonial secretary, instead of confirming the suspension, ordered Riddell's reinstatement when he should have apologized to the governor at a council meeting. Bourke, pointing out that Riddell's insults had been public while his apology would have been private, promptly resigned, and so on 5 December 1837 ended the colonial labours of the most popular governor New South Wales has ever had. Returning to England via Valparaiso, the Uspallata pass over the Andes, and Buenos Aires, he was offered first the governor-generalship of Jamaica (which he refused because the powers were too limited) and then—unofficially—the command of the British forces in India, which he declined for reasons of health. He retired to his estate at Thornfield in Limerick, lived there quietly for another 17 years, and died on 12 August 1855. (C.B., 1815; K.C.B., 1835).

Bowen, Sir George Ferguson (1821-1899), born in Ireland on 2 November 1821 and educated at Charterhouse and Trinity College, Oxford (B.A., 1844; M.A., 1847; hon. D.C.L., 1875; hon. LL.D., Cambridge, 1886), was trained for the law, but in 1847 was made president of the university of Corfu, and in 1854 chief secretary of the Ionian Islands. In this capacity he advocated the surrender of the southern islands to Greece and the retention of Corfu and Paxo (whose population was mainly Italian) within the British Empire. In 1859 Bulwer Lytton, then colonial secretary, made him first governor of Queensland, and for the next 20 years he was entirely concerned with various colonies of Australasia. During his eight years' term in Queensland he encouraged exploration, local defence, and the importation of Kanakas, but earned some unpopularity by refusing to allow the issue of unconvertible paper currency during a financial crisis. In 1867 he was transferred to New Zealand to succeed Sir George Grey, and soon found himself confronted by the rebellion under Te Kooti and by a simultaneous outbreak of Hauhaus on the west coast, but managed both to suppress the outbreaks almost entirely with local troops (the British regiments having been withdrawn) and by just treatment to soothe the disquieted Maoris and restore a healthy peace. His tact and energy were rewarded by promotion to the governorship of Victoria in 1872. Here he was involved in bitter quarrels between assembly and council, which are more fully narrated under Berry, Sir Graham, and on the whole question took the attitude that had been fatal to a predecessor, Sir Charles Darling, in McCulloch's time—that the dispute was of local, not Imperial, interest, and that he must therefore accept the advice of his ministers; there is no doubt, however, that he fully sympathized with Berry's actions. The British authorities were by this time more used than they had been in Darling's time to the political civil wars of the colonies, and Bowen got off lightly, being merely transferred in 1879 to the Mauritius, a little before his Victorian term had really ended. At the Mauritius (1879-1882) he did little more than routine work; but at his next post, Hong Kong (1882-5), he reconstructed the local legislature and ably kept the peace with France and China while those two countries were at war in 1884-5. Returning to England in 1886, he received many honours for his long and on the whole successful services, was entrusted in 1887 with a mission to Malta in connection with that island's new constitution, helped in the compilation of his memoirs (*Thirty Years of Colonial Government*), and died at Brighton on 21 February 1899. His first wife, Diamantina Countess Roma, daughter of the president of the Ionian senate in 1856, is commemorated in the names of a Queensland river and town.

One of Bowen's special characteristics was a readiness to correlate contemporary phenomena with the more ancient history which he studied lovingly to the day of his death. It was natural that at Corfu he should pursue Homeric studies and attempt (though in vain) to make indisputable the identification of the island with Homer's Ithaca. But Queensland was as full of classical reminiscences for him as Corfu, and the Darling Downs reminded him of Thessaly, while the squatter-selector controversies seemed a replica of Roman quarrels over the *ager publicus*. In New Zealand he launched out into

deeper waters; compared Te Kooti's rebellion with the Indian mutiny, and the tribal system existing in New Zealand with the remains of the clan system as it existed in Scotland at the beginning of the 18th century; and explained the Maoris with parallels from the Bible and Sir Walter Scott. To the severely practical colonial mind this savoured of pedantry; but a serious study of such parallels—especially of those drawn from Greek and Roman history—would have saved Australia many evil days. (C.M.G., 1855; K.C.M.G., 1856; G.C.M.G., 1860.)

Bowen. George Meares Countess (1803-1889), in no way related to the Bowens of the naval service mentioned below, was educated at the military college at Sandhurst and in 1821 commissioned lieutenant in the 39th regiment. In 1827 he accompanied a detachment of his regiment to New South Wales, but almost immediately resigned his commission to become, at Governor Darling's request, an assistant surveyor under the government. Darling in 1828 made him a commissioner 'for apportioning the territory' and in September granted him—as though he were still a military officer—2560 acres, which Bowen located on the Falbrook beyond Singleton. The colonial office, however, disallowed the commissionership, and Bowen retired from the service, had his grant transferred from the Falbrook to Mount Tomah beyond Windsor, and settled down in that district as a farmer and magistrate. His residence was at Bowen Mount on the Kurrajong Hills, but he began the erection of a fine stone mansion on the Bell's Line road near Mount Tomah, the remains of which are still known as 'Bowen's Folly.' Bowenfels, a township at the western extremity of the original Bell's Line, was named after him: but the name when given was purely English, Bowen Fells. As early as 1846, however, mapmakers had introduced the foreign spelling, though the older remained in use for many years later. Gipps made Bowen police magistrate at Berrima, but refused him leave to visit England in 1843. He died on 1 September 1889.

Bowen. John (1785?-1827), was one of a numerous family, nearly all connected with the navy, whose names occur frequently in early Australian history. At his death he was said to be 42 years old, which would make the date of his birth 1784-5; but King would hardly have entrusted the founding of a new settlement to a boy of 18. He was educated at the royal naval college, and left it in 1798 to join the navy (midshipman, 1798; lieutenant, 1802; commander, 1804; post-captain, 1805), serving at first under his father, James Bowen, who is discussed later. He served in the Mediterranean (1798-1800) and on the Cape station (1801), and in May 1802 was made junior lieutenant in H.M.S. *Glatton*, which reached Port Jackson on 11 March 1803. He at once volunteered for colonial service, and on the 18th King proposed to send him to Norfolk Island as acting-lieutenant-governor, but within 10 days cancelled this appointment and put him at the head of the expedition destined to make a settlement on Storm Bay. For his work on this task see Tasmania. During a visit to Sydney in January 1804 he heard of the renewal of the war between France and England, and at once asked to be relieved of his local duties so that he might return to Europe; after some confusion this was arranged, and he left Sydney for England on 21 January 1805, carrying King's despatches to the colonial office. It is usually stated that he fought at Trafalgar, was promoted post-captain immediately afterwards in honour of the victory, did escort duty with convoys from 1806 to 1809 in the *Camilla*, and served on the East Indies station in the *Salsette* in 1812-16; but it seems remarkable that a junior lieutenant of 1802 should be a post-captain by 1805. He died at Ilfracombe on 20 October 1827.

James Bowen (1751-1835), John's father, was born at Ilfracombe, entered the merchant service about 1766, and joined the navy about 1777. He was master of Lord Howe's flagship in the battle of the 1st of June, 1794, and by very rapid promotion was captain of his own ship within 15 months; in 1803 he was appointed a commissioner of the transport board, in 1816 a commissioner of the navy, and retired in 1825 with the rank of rear-admiral. He died on 27 April 1835. His services to the nation were numerous and important; but his only connection with Australia (outside his parentage of John Bowen) lies in his signature to letters as a transport commissioner or a commissioner of the navy. His brother Richard Bowen (1761-1797), of whom Nelson said 'A more enterprising, able and gallant officer does not grace His Majesty's naval service,' was in 1791 naval agent aboard the transport *Atlantic*, which on 18 August discovered, and took shelter from adverse winds in, a bay which he named Jervis Bay after his old commander. He also under Phillip's instructions sailed the *Atlantic* from Norfolk Island to Calcutta in the teeth of the north-east monsoon, was delayed for two months in India loading stores, started back with the vessel 'as deep in the water as a sand-barge,' and reached the island again within 7½ months from his departure. On returning to England he recommended the supplying of New South Wales with live stock from Madura and Timor. He was killed on 24 July 1797 during Nelson's attack on Santa Cruz. James Bowen, captain in the navy, who commanded the sea forces at Madeira when the *Investigator* visited that island in 1801, and after whom Flinders named Bowen in Queensland, was possibly Admiral Bowen, but may have been his eldest son.

A George Bowen, master of the transport *Albemarle* in 1791, did not belong to this family; neither did a 'Mr.' Bowen who was second mate of the *Lady Nelson* when Grant took her to Western Port and Port Phillip.

Bower-birds, perching birds belonging to the family Ptilonorhynchidae, peculiar to eastern and northern Australia and New Guinea. Many of the bower-birds are brilliantly plumaged; the majority build structures of various kinds, composed of sticks, round which they collect brightly-coloured objects, and in and about which they spend a great deal of time, arranging their treasures and playing with one another. These structures (generally called bowers) are quite distinct from the nests, which are of the ordinary cup-shaped form and are built in trees and bushes. The different genera of the family present great differences in habits, and in coloration both of the birds and of the eggs.

The genus *Ailuroedus* contains the cat-birds, so called because their notes strikingly resemble the mewing of cats. They frequent tropical scrub country, feed on jungle fruits, and build bulky nests in bushes, not far from the ground. Their two or three eggs are cream-coloured,

without markings. They are not known to build any sort of bower. The two Australian species are the Green Cat-bird (*A. crassirostris*) of eastern New South Wales and south-eastern Queensland, and the Spotted Cat-bird (*A. melanotus*) of north-eastern Queensland; a third species is found in New Guinea. They are bright green above and yellowish-green below, spotted all over with white; they have very stout bills. The Tooth-billed Bower-bird (*Scenopoecetes dentirostris*) of north-eastern Queensland, the sole member of its genus, is characterized by tooth-like notches on the sides of its stout bill. It is dark greenish-brown above and brownish below with darker streaks. It frequents tropical scrubs. Its nest is a fragile structure composed of sticks, and the two eggs are of a greenish cream-colour without spots. This species is much more melodious than the cat-birds; it utters clear liquid notes, and mimics the notes of other birds. It does not construct a bower, but clears all the dead leaves

Bower of Satin Bower-bird.

and rubbish from a piece of ground (usually under a bush) and on it spreads a number of leaves spaced separately at about equal intervals apart. These are renewed every day, the withered leaves being removed, and the fresh leaves placed with their lighter side uppermost.

The Satin Bower-bird (*Ptilonorhynchus violaceus*)—also the only member of its genus—inhabits the coastal districts of eastern Australia from Queensland to Victoria. Young males and females are greyish-green above with brown wings and tail, yellowish beneath, with crescent-shaped dark-brown tips to the feathers. The eyes in both sexes are blue. When about seven years old the male acquires his adult plumage and is a rich, satiny, shiny blue-black all over. Satin-birds construct elaborate bowers (often called 'runs') in secluded places among the forest-covered hills, usually under the shade of an overhanging branch. Male birds do most of the work, the females occasionally assisting them. The base of each bower is a platform of interwoven sticks, on which are set two rows of more flexible twigs with their ends propped against each other, so as to leave a clear passage-way beneath. All round these 'runs,' and especially near the entrances, bright objects collected from the vicinity—such as shells, bones, feathers and flowers—are spread about, blue objects being especially sought after. At the beginning of the breeding-season the males show off before the females near and within these bowers, running round them and through the passage with bright objects in their beaks. Each bower is the playhouse for a colony of birds, and is in no way connected with nesting. The nests are cup-shaped structures of sticks placed in low bushes; the two eggs are cream-coloured, with blotches, spots, and streaks of brown and grey. Satin-birds, being fruit-eaters, visit orchards when the fruit is ripe, and are shot by the orchardists, so that their numbers are diminishing.

The Regent-bird (*Sericulus chrysocephalus*),

Regent-bird.

again the sole member of its genus, is confined to the scrubs of south-eastern Queensland and north-eastern New South Wales. The male—the handsomest of all bower-birds—is velvety black, with head, neck, back, and some of the wing-feathers a rich orange-yellow. The female is brown above, with a whitish head and under-parts, and black patches on the head and throat. This species feeds on insects as well as on berries and other fruits; its call is a single whistle. The nest is a slender structure, usually placed in a bunch of trailing creepers; the eggs are yellowish, with blotches of brown and grey and fine stripes and scrawls of reddish-brown. The bower is like that of the satin-bird but smaller and sometimes without any platform of sticks. It is decorated chiefly with berries, leaves, and snail-shells.

The Golden Bower-bird (*Prionodura newtoniana*) of north-eastern Queensland is golden-yellow in colour, with a broad crest on the head; the female is olive-green. It constructs bowers in which one side is composed of longer sticks than the other, so as to overlap it, and

decorates them with flowers. The females build bowers for themselves, smaller than those constructed by the males. The nest, built principally of leaves, is placed in a hollow in a stump or the buttress of a fig-tree. The two eggs are shining white.

The four species of *Chlamydera* are brownish birds, more or less spotted with paler colouring. The Spotted Bower-bird (*C. maculata*) is found throughout the inland districts of eastern Australia, the Western Bower-bird (*C. guttata*) in the centre and north-west, and the Great Bower-

Spotted Bower-bird.

bird (*C. nuchalis*) all along the north coast of the continent. These three species are adorned with a bright lilac-pink band across the back of the neck, larger in the male than in the female, and absent in young birds. The fourth species, the Fawn-breasted Bower-bird (*C. cerviniventris*), lacks this lilac band. Its range extends from Cape York to southern New Guinea and the Louisiade Archipelago.

The species of *Chlamydera* build longer bowers than their relatives, forming short avenues of twigs, inside which are grasses kept in position by stones at their base. Great piles of water-worn stones, shells, bones, and other objects are accumulated at each end of the bower, or are sometimes arranged in rows radiating outwards like paths. The bowers are the resort of many individuals, which apparently assist in their construction and chase one another through the passage. The nest is placed in a bush, and the eggs have a fine sea-green ground colour, blotched and marked like those of the regent-bird.

W.B.A.

Bowls. The first game of bowls played within what is now the Commonwealth was between T. Burgess and F. Lipscombe, at Lipscombe's home on Sandy Bay near Hobart on 1 January 1845. Burgess won the 'odd game out of 25.' In the same year William Turner laid down a green at his hotel on the Sandy Bay-road, which he named the Bowling Green Hotel; the green was in existence in the late fifties, and its stone retaining walls are still visible, the hotel having been converted into a private residence. On 28 October 1846 Turner formed the first bowling club, which included officers of the 96th regiment and leading citizens of Hobart. In 1852 a match between military and civilian teams was watched by nearly 1000 spectators who had paid for admission. The civilian team won.

The oldest existing green in Australia is that of the Melbourne club at Windsor, which was laid down by John Campbell in 1864 and opened on 22 October in that year. Campbell's attempts to form a club before the green was ready failed, and the expense of constructing it almost brought him to bankruptcy; but as soon as the green was in use there was a rush of members, and by the end of the year 182 were enrolled. The St. Kilda club was formed in the same year, its green being opened in 1865; the Fitzroy club in January 1865, and its green in November; the Ballarat also in 1865, the West Melbourne (now the City) in 1866, the Carlton in 1868, and the Richmond (now defunct) and Richmond Union in 1869. On 23 July 1880 these clubs, with three of later growth, formed the Victorian Bowling Association, with Samuel Amess as first president and M. Ellis as first secretary.

An engraving in the Mitchell Library at Sydney shows that the game was played in the grounds of the Sir Joseph Banks hotel at Botany so far back as 1854. It was, however, Alexander Johnstone of Parramatta who introduced the game to New South Wales under club conditions. For him Thomas Eades (also of Parramatta) in 1867 turned the first set of bowls made in the colony, and Johnstone practised with them in solitude in a paddock at Elizabeth Farm, until neighbours began to doubt his sanity. After a time he persuaded Andrew Payten of the Woolpack hotel to lay down a rink, and in 1869 three rinks were in use there. The Woolpack club—the first in the colony—was formed in 1870. In 1872 A. T. Holroyd (q.v.) laid down a rink at Sherwood Scrubs, his home near Parramatta, and formed a club composed mainly of English university men; in 1874 he published a set of 'rules which will regulate bowl-playing on my green.' In the same year W. F. Burkitt, an assistant-master at The King's School, Parramatta, completed a rink in the school grounds. The Woolpack club lived until 1880, when it was replaced by the Parramatta Bowling club.

In Sydney a club was formed in 1876 to play on a green made by Charles Moore, curator of the botanic gardens, in the Domain facing Macquarie-street; in 1878, however, its site was required for the exhibition buildings. Private greens were owned by E. W. Fosbery (inspector-general of police) and by John Young of Annandale, who in December 1878 formed the Kentville club and became known as 'the father of bowls.' Early in 1880 Young invited the Victorian clubs to send teams to Sydney, and on 12 April 1880 the first intercolonial match was played on the Kentville green, Victoria winning by 21 points (112 to 91). On 22 May was formed the New South Wales Bowling Association, comprising the Kentville, Balmain, Parramatta and City clubs, with John Young as first president and Thomas Richard Smith as first secretary. Between 1880 and 1896 19 intercolonial matches were played, Victoria winning 12 and New South Wales 7. In 1896 a new series of matches was inaugurated—three in Sydney and three in Melbourne each year, the rubber of each set to count as a win. Under this arrangement—only one set was played in 1896, 1912, 1913, 1917, 1919 and 1921, and no sets at all in 1897, 1899, 1901, and 1914-16—40 sets had been played up to the end of 1924 (one set in 1923 having been left unfinished), of which Victoria had won 23 and New South Wales 17.

In Queensland the Metropolitan Bowling club was formed in September 1878, using as a green

the lawn of the botanic gardens; this being taken for croquet-players in 1879, and a substitute green offered by the colonial authorities proving useless, the club in 1881 opened a green just beyond the railway-gates at Roma-street. This was resumed by the railway department in 1893, and the club then amalgamated with the Booroodabin (Breakfast Creek) club, which was formed in 1888. In 1903 the five clubs then in existence—Booroodabin, South Brisbane, Maryborough, Darling Downs, and Doon Villa (at Maryborough)—formed the Queensland Bowling Association. The first match between Queensland and New South Wales was played in 1904; it inaugurated a series of home-and-home matches of which (as there were no contests in 1914-7 and only one in 1918) there have been 33. Queensland has won 18 and New South Wales 15.

After the disappearance of Turner's green in the late fifties there is no record of Tasmanian bowls until 1883, when a club was formed at Launceston. In 1891 the Hobart club was formed, and in 1902 the two clubs formed the Tasmanian Bowling Association. Launceston produced a second club (the A.B.C.) in 1898, and Hobart others in 1905 (the Buckingham) and 1907 (the Sandy Bay). In 1904 a Tasmanian team visited New South Wales.

In South Australia the Adelaide club was formed on 18 February 1897, its green being opened late in 1898. The Adelaide Oval club was established in 1901, and in 1902 these two clubs formed the South Australian Bowling Association. Intercolonial matches followed, the first against New South Wales in 1902, the first against Western Australia in 1903; but these have not become regular fixtures.

In Western Australia the Perth club was formed in 1894, and its green opened in 1895. The Fremantle club, formed in 1896, and the Swan club, formed at East Guildford in 1897, joined in September 1898 to form the Western Australian Bowling Association.

The strength of the various State associations at the end of 1924 was:—Victorian, 67 metropolitan clubs, 82 affiliated country clubs; New South Wales, 32 metropolitan, 51 country; South Australian, 28 metropolitan, 24 country; Queensland, 29 in all; Western Australian, 19 metropolitan, 17 country; Tasmanian, 17 in all.

In April 1911 an Australian Bowling Council was formed to manage inter-State and international games, and under its auspices the first bowling carnival was held in Melbourne in December 1912; subsequent carnivals have been held in Brisbane (1914), Adelaide (1921-2) and Perth (1924), each controlled by the State association under the council's auspices. The team championship was won in 1912 by Victoria, in 1914 by Queensland, in 1921 by South Australia, and in 1924 by Western Australia—in every case the local team was the winner.

In 1899 an attempt was made to arrange a visit from a representative English team, but the lack of a central body in England made negotiations difficult. In August of that year, however, the International Bowling Association was on John Young's initiative formed in London, with Lord Jersey (q.v.) as its first president; and in 1901 a combined New South Wales and Victorian team visited England, playing 22 matches, of which they won 11 and drew one. A New South Wales team went to England in 1912, winning 30 games and losing 24. The first team representing all Australia visited Britain in 1922 under the joint auspices of the Australian Bowling Council and the International Bowling Board of Great Britain; out of 40 matches it won 23 and drew one.

In 1925 the Australian Bowling Council decided that all bowls should in future be standardized by the table test; that all, whatever their material, should conform to a standard shape; and that the maximum weight for a given major diameter should be determined according to a fixed scale, the maximum for a ball of 5 3/16 in. diameter being 3 lb. 8 oz., that for a ball of 4¾ in. diameter 3 lb. 2 oz., and for intermediate sizes in proportion. A variation of 1/32 in. is allowed either way, and the diameter between discs must be from 7/16 to ½ in. less than the major diameter.

W.A.B.
J.P.M.

Box, a name applied chiefly to a section of the genus *Eucalyptus* (q.v.), but occasionally to trees of other genera. The brush box is a *Tristania,* the China box a *Murraya.*

Box-fishes (Ostraciidae), an extraordinary group of fishes which, though generally distributed throughout temperate and tropical seas, are more plentiful and of greater variety in Australian waters than elsewhere. The head and body are encased in a hard carapace formed of scutes immovably anchylosed together, leaving only the fins free; these project upon short fleshy bases. The carapace is commonly provided with several keels (or crests) and with strong fixed spines that change their form with growth, the young being more spinate than adults. Most of the species are highly ornate, with amazingly brilliant colours and patterns. They are also known as coffer- or trunk-fishes. A common tropical representative is called cow-fish, on account of two long spines that project forwards from the forehead like a pair of horns. They are related to the leather-jackets and toadoes, and, notwithstanding their forbidding appearance, are sometimes eaten by the aborigines, who roast them in their shells. The Horned Box-fish or Cow-fish (*Ostracion cornutus*) is a common tropical species which occasionally wanders southwards to Port Jackson. It has two long spines projecting forward from the forehead like horns, and two others pointing backwards near the tail.

Boxing. See Pugilism.

Boyce, William Binnington (1804-1889), born at Beverley in Yorkshire on 9 November 1804 and from his early youth devoted to religious duties, was in 1829 accepted as a missionary probationer and sent to South Africa by the Methodist committee. Here he spent 13 laborious years, mostly in Kaffraria, and earned a reputation for scholarship as well as for courage. In 1843 he returned to England, was for two years in charge of a church at Bolton, and in 1845 was despatched by the English conference to New South Wales to set up the machinery for local government in Church affairs which the conference was ready to grant to its Australian adherents. He reached Sydney in 1846, and soon became a prominent figure in the life of the colony. When in 1850 the university of Sydney was founded, Boyce was one of the 16 original senators, and a member of the first library committee; in later years he gave the library a valuable collection of Oriental literature. His work for his Church was continuous and masterly. He was general superintendent of missions before the establishment of the Australasian conference, and presided at the first two meetings (1855

and 1856) of that conference. In 1847 he published a newspaper, the *Gleaner*, and in the next year incorporated it with the *Christian Standard*. When local self-government in church affairs had been established, Boyce returned to England and for 18 years worked there as one of the secretaries to the foreign missions committee. In 1875 he came back to Sydney, settled at Toxteth Park in the Glebe, and officiated occasionally at the chapel erected there by Sir G. Wigram Allen (q.v.). During these years he took up with zeal the study of philosophy and history, and published in 1878 *Six Lectures on the Higher Criticism of the Old Testament* and in 1884 an *Introduction to the Study of History*, both based on very wide reading of English and German authorities. He died suddenly at Toxteth on 8 March 1889.

J.C.

Boyd, BENJAMIN (1803-1851), born in London and educated in Scotland, in 1824 returned to London to enter a financier's office; later on he became a member of the stock exchange and an original director of the Union Bank of London. In 1840 he founded the Royal Bank of Australia, and in 1841 the Australian Wool Company. Towards the end of that year he decided to visit Australia and establish a branch of the bank there, and on 23 December left Plymouth in the yacht *Wanderer*, reaching Sydney on 18 July 1842. He took with him his brother James Boyd and the artist Oswald Brierly (q.v.), and four vessels—the *Seahorse*, *Juno* and *Cornubia*, steamships, and the schooner *Velocity*—flying his 'two bees' flag and carrying his stores, preceded him to Port Jackson. In 1843 he opened his branch bank on Church Hill, and entered the whaling industry, making his headquarters for this purpose at Twofold Bay, where he founded twin townships (Boyd Town and East Boyd) astride the Towamba River. His main object, however, was to acquire wealth in pastoral enterprises; Boyd Town was to be the shipping centre for the Monaro plains, to which he constructed a road; and he took up under pastoral licence 800 square miles of country along the Murray between the Ovens and the Campaspe, as well as several blocks near Deniliquin. He also imported blood stock, and made himself so popular in Melbourne that from September 1844 to September 1845 he represented Port Phillip in the Sydney legislative council. Both on the Murray runs and at Boyd Town he employed Kanakas, being the first man to import them (in 1847) as labourers to Australia. Unfortunately for him they were ill-treated by their overseers, got out of hand, and became such a nuisance that the government ordered their deportation. For a time his many enterprises flourished, and Boyd Town was a regular port of call for vessels trading between Hobart, Melbourne, and Sydney; but in 1849 the crash came, and a few years later the bank —with whose funds the whole business had been financed—was wound up. The shareholders, in addition to losing their capital, had to make good a deficiency of £80,000. Boyd, who had been removed from control, was allowed to retain three whalers, the yacht *Wanderer*, and some land at Twofold Bay. On 26 October 1849 he sailed from Sydney in the *Wanderer*, went off to the Californian gold diggings, but met with no success, and then decided on a cruise amongst the islands of the Pacific; it was asserted by one of his companions that he hoped to establish a 'Papuan republic or confederation.' The *Wanderer* left San Francisco on 4 June 1851, and on 10 September reached San Cristoval in the Solomons. On 14 October they anchored in a small bay on the west coast of Guadalcanar, and next morning Boyd (taking one of the native crew) went on shore to shoot game, and was never seen again. About breakfast-time the natives made an attack on the yacht, and with great difficulty were beaten off. A landing and search for Boyd proved unsuccessful, no traces of him being found but his belt and some wadding from his cartridges. The search was repeated during several days, but without result, and on the 19th the *Wanderer* sailed for New South Wales, reaching Port Macquarie on 13 November; there she grounded off the southern headland and went to pieces. In 1854 rumours were current in Sydney that Boyd was still alive on Guadalcanar, but a renewed search had no success, and it is practically certain that he was killed by the natives soon after his landing on 15 October.

The most trustworthy account of Boyd's life may be found in the *Journal* of the Royal Australian Historical Society (vol. ii); and an account of Boyd Town in Wells's *Gazetteer of the Australian Colonies* (1848) is so elaborate as to raise a suspicion that Boyd subsidized the book. Webster's *Last Cruise of the 'Wanderer'* is also useful.

Brabyn, JOHN (1775-1835), apparently English-born, is first heard of when appointed to the New South Wales Corps (q.v.) on 6 May 1795 (ensign, 1795; lieutenant, 1800; captain, 1808; captain in the veteran company, 1811). He reached Port Jackson on 11 February 1796 in the *Marquis Cornwallis*, after a voyage almost frustrated by an attempt at mutiny among the troops and convicts. For some years he was stationed at Norfolk Island, where in 1800 he was concerned in the punishment of another convict conspiracy. In 1801 he returned to Sydney and was stationed at Parramatta, obtaining a grant of 200 acres from King and buying an additional 100 acres, on which he grew wheat and kept a few sheep. King liked him and eulogized his conduct during the Castle Hill mutiny of 1804. During Bligh's term he took part, as senior lieutenant, in the protest against the participation of Atkins in Macarthur's trial and in the deposition of Bligh that followed; at the end of 1808 he was transferred to Port Dalrymple, and then heard that on 13 February he had been gazetted captain. (These delays seem to have been frequent; Brabyn's lieutenancy, for instance, was gazetted in London on 15 August 1800, but he still ranked as ensign in Sydney on 15 September 1801.) At Port Dalrymple he took over charge from Paterson, allowing him to go to Sydney and supersede Foveaux; Paterson seems to have objected to his methods of administration, but Macquarie when he arrived found no fault with them. Consequently, although he was sent home with the Corps, he was on 5 February 1811 transferred to the veteran company and allowed to return to the colony. In 1817 he retired from military service and settled down to farming, obtaining in 1819 a grant of 1200 acres near Prospect (and others later); he was made magistrate at Windsor, but in 1827 was still reckoned a military officer on full pay, though in no way connected with the then veteran companies under Colonel Dumaresq. He died on 1 August 1835.

Brachychiton, a large, chiefly tropical genus of the family Sterculiaceae, most abundant in tropical Asia. Twenty species are endemic in Australia; they consist of trees with

variously divided leaves, flowers without petals —the enlarged coloured calyx provides a substitute—and frequently unisexual. *B. quadrifidus*, a species confined to Queensland and the Northern Territory, has brilliant scarlet fruits which, when open, display black seeds and are very ornamental. The seeds are edible, and taste like filberts. The mucilaginous substance of the fruit is also eaten. The roots of *B. trichosiphon* (the 'Ketey' of northern Queensland aborigines) are eaten without any preparation. The timber of *B. discolor* is white and soft when cut, but hardens in drying, and makes good shingles. The bark yields a strong, useful fibre like bass or Russian matting. *B. rupestris* is described under BOTTLE-TREE, and *B. acerifolius* under FLAME-TREE. See KURRAJONG.

Brachycome, a genus of the family Compositae, chiefly indigenous to Australia; a few species occur in New Zealand. It has involucral bracts in 2 rows nearly equal; marginal florets numerous with narrow rays; achenes flat

Swan River Daisy.

with winged margins or obtusely 4-angled; pappus short or obsolete. *B. iberidifolia* (Swan River Daisy), an annual with blue or white flowers, is much cultivated as a border plant in gardens. *B. nivalis*, one of the snow daisies from Mount Kosciusko, is a white-flowered species with feathery foliage: *B. decipiens*, a coastal species, is also cultivated, and bears a strong resemblance to the common English Daisy (*Bellis perennis*).

Bracken-fern. See FERNS.

Braddon, SIR EDWARD NICHOLAS COVENTRY (1829-1904), son of Henry Braddon of Skisdon in Cornwall, and elder brother of the novelist best known as Miss Braddon, was born on 11 June 1829. In 1847 he went to Calcutta to work for a cousin's firm there, but after a few years joined the government railway service as assistant in the Santhal district, where he helped to suppress an outbreak. This brought him the appointment of assistant-commissioner (1857). During the Mutiny he raised a Santhal battalion, and served under Sir George Yule with much credit. For the next 20 years he occupied various posts in the Indian revenue service. Retiring on pension in 1878, he settled on the land in the north-west of Tasmania. Next year he entered the assembly as member for West Devon, became leader of the opposition in 1886 and (after refusing the premiership) joined the Fysh ministry in 1887 as minister of lands and works. In 1888 he was the Tasmanian representative on the federal council (see FEDERATION), and late that year left the ministry to become agent-general. Recalled to Tasmania at the end of 1893, he was re-elected for his old constituency and next year became premier. He retained this office until late in 1899, meanwhile taking a large share in the establishment of federation; he represented Tasmania at the convention of 1897-8, and was mainly responsible for the famous 'Braddon' clause (q.v.), also known as the 'Braddon Blot.' Elected to the federal house of representatives in 1901, he sat as a freetrader until 1904, when he died on 2 February. (K.C.M.G., 1891; P.C., 1897.)

Braddon Clause, THE. When the constitution of the Commonwealth was being shaped by the convention of 1897-8 (see FEDERATION), the disposal of Commonwealth revenues was found to be a difficulty. The various colonies had derived a good deal of their public funds from customs duties, which under any genuine form of federation must inevitably be collected by the central government. To avoid dislocation of colonial finances it was obviously necessary to secure to the several States a return of part at least of this customs revenue; there was also a good deal of hesitation about giving the new Commonwealth liberty to spend as much as it might like to. At the Adelaide meeting, therefore, it was agreed that federal expenditure should not exceed £1,550,000 annually, that the surplus should be distributed among the States in proportion to population, and that the sum so distributed should for five years after the imposition of uniform federal duties be not less than they had received in the last year under their own scales of duties. During the discussion on this scheme F. W. Holder of South Australia suggested that the Commonwealth should return to the States a fixed proportion —say 70 per cent—of the customs revenue it collected; but the suggestion fell flat at the time.

During the debates in colonial legislatures on the Adelaide draft of the Commonwealth bill, New South Wales deleted all these provisions,

and no colony except South Australia expressed satisfaction with them. At its Sydney meeting, therefore, the convention cancelled them and referred the whole matter to the finance committee; and at the Melbourne meeting in 1898 a completely new scheme was submitted, abolishing all guarantees. This did not please Victoria or Tasmania, but New South Wales advocated it.

After the third recommittal of the bill Sir Edward Braddon brought up the first draft of a clause providing that, out of the net customs and excise revenue, not more than one-twentieth should be spent by the Commonwealth in the exercise of its original powers, not more than four-twentieths should be spent upon transferred services, and the remaining three-fourths should be distributed among the States. The proposal was made in the small hours of the morning, towards the close of the sittings; it had been in print for some days; the convention had already discussed the whole question fully; and it was carried with hardly any debate by 21 votes to 18, the Victorians and Tasmanians voting for it and all the representatives of New South Wales (except W. J. Lyne) against it. Next day it was reconsidered, and Edmund Barton made an effort to limit it to five years. But his amendment was negatived, and the clause passed with an amendment providing that, when any part of a State's public debt was taken over, revenue returnable to that State might be devoted to the payment of interest. Finally Braddon consented to simplify his proposal by allowing the Commonwealth to spend one-fourth of the net receipts.

This clause was hotly opposed in New South Wales, where freetraders argued that, by compelling the Commonwealth to raise four times as much revenue as it required for its own use, the clause forced on the new central government some form of high protective duties. When (as is told under FEDERATION) the affirmative vote in New South Wales did not prove large enough to carry the bill, and Reid demanded of the subsequent premiers' conference amendments as the price of his support for a new referendum, one of them limited the duration of the Braddon clause to ten years after the Commonwealth came into being, unless the federal parliament liked to let it function longer. The clause, therefore, as embodied in the constitution (87) stood as follows:—'During a period of ten years after the establishment of the Commonwealth and thereafter until the Parliament otherwise provides, of the net revenue of the Commonwealth from duties of customs and of excise not more than one-fourth shall be applied annually by the Commonwealth towards its expenditure. The balance shall, in accordance with this Constitution, be paid to the several States, or applied towards the payment of interest on debts of the several States taken over by the Commonwealth.'

In actual working the clause proved unsatisfactory both to the Commonwealth and to the States; it deprived the one of funds that were often sorely needed, and did not function equally among the others—Queensland, for instance, in five years and Tasmania in two did not receive the full three-fourths of their share of revenue, since the clause did not specify that each individual State must receive that proportion, but only that in the aggregate that proportion must be distributed. Hence originated the frequently heard nickname, 'the Braddon Blot.' During the ten-years' term many attempts were made to recast the financial provisions of the constitution, and the argument that always induced the representatives of the States to modify their demands was that at the end of ten years the Commonwealth need not hand over any revenue at all. In August 1909, however, Alfred Deakin arranged with the State premiers that from July 1910 onwards the Braddon clause should disappear, and the Commonwealth should for the future pay each State 25s. per head of its population.

Under the Braddon clause the Commonwealth paid to the States in 9½ years (January 1901 to June 1910) the sum of £68,140,353. But, owing to the action of another clause (94) which ordered that the Commonwealth should also hand over to the States its whole annual surplus, the total payment to the States amounted to over 74 millions, or more than 81 per cent of the customs and excise revenue collected.

Brady, JOHN, born in Cavan, Ireland, was for 19 years a missionary in the island of Bourbon, but met Dr. Ullathorne while on a visit to Rome in 1837, was persuaded to offer his services for the Australian mission, and was detailed for duty at Norfolk Island. Reaching Sydney on 24 February 1838, he was sent by Bishop Polding to Windsor—a change which led to trouble with the colonial office, Dr. Ullathorne having secured the appointment on the ground that Norfolk Island was badly in need of a chaplain. At Windsor Father Brady was stationed for some years, and while there made a particular study of the needs and the language of the aborigines. In 1843 Dr. Polding, who trusted him greatly, sent him as vicar-general to the Swan River settlement. He reached Perth on 13 December, founded a church there before the month's end, and in the following April sailed for Europe to procure help for the new mission; while at Rome on this errand, he was consecrated bishop of Perth on 18 May 1845, and early in 1846 returned to Western Australia with a large number of priests and other helpers, including Dom Serra and Dom Salvado (q.v.). The diocese was extremely poor, and Dr. Brady was beset by financial difficulties to such an extent that he for some time lived in a closed-in belfry. In 1849 his health failed, and he was given Dom Serra as coadjutor. This dual administration of Spanish and Irish ecclesiastics led, unfortunately, to strained relations between them, which were further complicated by financial difficulties, and in 1850 Dr. Brady visited Rome to find some way out of the confused situation which had resulted. In October 1851, after the bishop had returned to the colony, Pius IX suspended him from his functions. In August 1852 he left Western Australia and went to Rome, eventually settling at Kilmore in Ireland; but he never resigned his see, and was still bishop of Perth when he died in France on 2 December 1871. While in Rome in 1845 he published a short *Descriptive Vocabulary of the Native Language of West Australia.*

E.M.O'B.

Bragg, SIR WILLIAM HENRY, born at Wigton in Cumberland, England, on 2 July 1862 and educated at King William's College in the Isle of Man and at Trinity College, Cambridge (B.A., 1884; M.A., 1887; honorary fellow of his college), was in 1885 appointed Elder professor of mathematics at the university of Adelaide. In 1895 he was elected to the council of the South Australian school of mines, and in 1898 to the council of the university. In 1907 his work

on radio-activity gained him a fellowship of the Royal Society, and in 1908 he left Adelaide to become Cavendish professor of mathematics at the university of Leeds. Thence in 1915 he went to London as Quain professor of physics at the university of London, and in 1923 became Fullerian professor of chemistry at the Royal Institution, director of the institution, and director of the Davy-Faraday research laboratory. His chief interest in all these positions has been the investigation of radio-active substances and phenomena. For his work he has received numerous honours, including the D.Sc. degree of Manchester (1914), Leeds (1919), and Trinity College, Dublin (1920); the Rumford medal of the Royal Society; and the membership of learned societies in France, Italy, Holland and Denmark. In conjunction with his son, W. L. Bragg, he has also received the Nobel prize (1915), the Barnard gold medal of Columbia university in the United States, and the gold medal of the Société Italiana della Scienze. He has published many papers in the *Philosophical Magazine*, the *Transactions* of the Royal Society, and similar periodicals, and in 1924 published *Concerning the Nature of Things*, founded on a series of lectures given at the Royal Institution. (C.B.E., 1917; K.B.E., 1920.)—His son, WILLIAM LAWRENCE BRAGG, born at Adelaide on 31 March 1890 and educated at St. Peter's College, Adelaide, the university of Adelaide (B.A., 1908), and Trinity College, Cambridge (M.A., 1912), in September 1919 succeeded Sir Ernest Rutherford as Langworthy professor of physics in the university of Manchester. Honours obtained in conjunction with his father are mentioned above. During the war he served in France as technical adviser on sound-ranging (1915-9), and was awarded the military cross and the O.B.E.

Brassey, THOMAS, 1st Earl Brassey (1836-1918), eldest son of Thomas Brassey a well-known railway contractor, was born on 11 February 1836, educated at Rugby and Oxford (B.A., 1859; M.A., 1862; hon. D.C.L., 1888), and trained for the law, but soon divided his time between yachting, politics, and the normal life of a country gentleman. He sat in parliament as member for Devonport in 1865, and represented Hastings from 1868 to 1885, taking especial interest in naval matters and being a civil lord of the admiralty in 1880-4 and parliamentary secretary in 1885. The main story of his life is of purely English interest; but on 25 October 1895 he became governor of Victoria, and held the position till 31 March 1900. His term of office was on the whole uneventful, as Victoria was recovering slowly from the financial crisis of 1892-3. He is best-known as the master of the yacht *Sunbeam*, in which he voyaged over 300,000 miles, and as the founder of the *Naval Annual*, which his son the 2nd earl edited from 1890 to his death. In 1886 Brassey was raised to the peerage as Baron Brassey, and in 1911 was made an earl. He died on 23 February 1918; his son dying on 12 November 1919, the peerage became extinct. (K.C.B., 1881.)

Bray, SIR JOHN COX (1842-1894), son of T. C. Bray, was born in Adelaide on 31 May 1842, educated at St. Peter's College and privately in England, and trained for the law. Admitted to the South Australian bar in 1870, he entered parliament in 1871 as member for East Adelaide, and sat for that constituency continuously until his resignation in 1892. He soon took a prominent place in the house, becoming minister for justice in the Blyth ministry (March-June 1875), attorney-general in the Colton ministry (June 1876-October 1877), leader of the opposition from that year to 1881, and premier from 1881 to 1884. In 1885 he joined the Downer ministry as chief secretary, and later as treasurer (1886-7); in 1888 he was elected speaker, but resigned in 1890 to become chief secretary in the Playford ministry, and left politics altogether in 1892 to take up the colony's agent-generalship in London. Illness compelled him to resign this in 1894, and his death at sea followed almost immediately on 13 June in that year. In his 21 years of political life (eight of them spent in office) there is little of actual achievement to consider. But he took much interest in federation, represented his colony in the intercolonial conference of 1883, presided over the Australian Natives' Association conference of 1890 which declared for federation, and was one of the South Australian representatives at the convention of 1891. (K.C.M.G., 1890.)

Bread. Bread made in Australia differs from that made in Europe (*a*) because the method of baking is different, (*b*) because the flours used are of a different quality. The European (ferment) system of bread-making consists in mixing a certain amount of flour with yeast, allowing the yeast to work for a while, and then adding the rest of the flour and water. In the Australian (straight) system, which is quicker and involves less handling, the flour and water are mixed first, and yeast and a little salt added; the mixing is done with machines, some of which can take 1000 lb. at a time. After mixing, the dough is turned into a trough to ripen and rise; thence it goes to a hopper, and thence to a dividing machine, in which it is cut into pieces weighing slightly more than 4 lb. (for a whole loaf) or 2 lb. (for a half loaf), since weight is lost in baking. The difference in quality is more important. Any wheaten flour makes a dough that is sticky and elastic, so that it will hold, and be inflated by, the gas from fermentation; but some wheats produce stickier flour than others, so that they 'rise' better, hold more water, and make a larger loaf from the same quantity of flour. These are called 'strong' flours. Australian wheats, thanks to W. J. Farrer (q.v.), yield a flour stronger than any others except those grown in Manitoba.

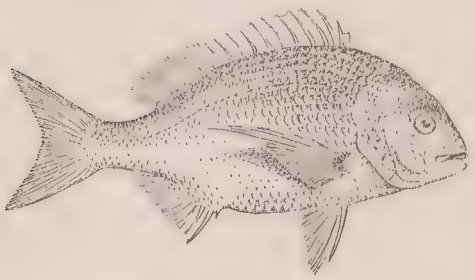
Of late years practical research into the science of bread-making has been carried on by Professor H. G. Chapman of the university of Sydney, aided by the Commonwealth advisory council of science and industry, and by the government of New South Wales, which built him a bakehouse at the Sydney technical college. Here bread has been regularly produced three times a week since 1916, the whole process being completed between the hours of 9 a.m. and 6 p.m. under simple but exact conditions of weight and temperature. Every dough is made with 250 lb. of flour, and consistently yielded 174 2lb. loaves, i.e. 1392 loaves to the ton of flour, or 104 to the bag. The weight of the bread, 15 hours after baking, averaged 354 lb.—6 lb. over the legal weight. The yeast was carefully made of uniform strength, and simple bacteriological methods ensured purity and freedom from acids.

H.G.C.

Bream, a vernacular name applied by fishermen of widely different fishes that have nothing

in common beyond a very superficial resemblance. The true bream of Europe is a freshwater fish of the carp family (Cyprinidae), but in Australia the name is generally applied to marine fishes of the family Sparidae.

The Black Bream (*Sparus australis*) is one



Black Bream.

of the best-known and most prized of all fishes occurring on coasts south of the tropics. It occasionally attains a weight of seven pounds, but is usually much smaller. It is an excellent food-fish, and is marketed in enormous quantities throughout the year, being secured by net-fishermen in estuaries and inlets. It also affords great sport to anglers, and its reputation as a game fish is such that trophies for its capture under various conditions are awarded by all fishermen's associations. This fish and an allied species, the Tarwhine (*S. sarba*), are also known as silver bream. The tarwhine is very widely distributed throughout the Indo-Pacific region, and extends southward as far as Port Jackson; it has a less pointed snout than the black bream, and has yellowish stripes along each row of scales on the sides. Another tropical species of similarly wide range, the Pikey Bream (*S. latus*), is so named on account of a long and strong spine in the anal fin; it occurs on the coasts of the northern half of Australia, together with lesser known relatives. The Tasmanian 'black bream' is a blackfish, q.v. See also BLACKFISH, BONY BREAM, DRUMMER, EMPEROR BREAM, SNAPPER, TREVALLY. A.R.McC.

Bremer, SIR JAMES JOHN GORDON (1786-1850), scion of a naval family, was in accordance with the custom of the times entered as a first-class volunteer in the Nore guardship when only eight years old, joined the naval college at Portsmouth when 11, and five years later was appointed to H.M.S. *Endymion*. For the next 20 years he served efficiently but unobtrusively in various oceans (lieutenant, 1805; commander, 1807; captain, 1814; rear-admiral, 1849). When P. P. King (q.v.) in 1823 proposed that the British government should make a settlement on the northern coast of Australia, Bathurst sent Bremer in H.M.S. *Tamar* to take formal possession of the strip of coast and islands between 130° and 135° E. The assigned reasons are worth noting: they were (*a*) to provide a commercial base for English merchants trading with the Dutch islands, (*b*) to provide a naval base from which the trade of the East India Company and of private merchants with China could be protected against hostile attacks. If, however, some other Power had already seized the region, Bremer was to accept the fact and make a settlement eastwards on the Liverpool River. In those days, evidently, it was not intended that Britain should claim the whole of Australia. Leaving Port Jackson on 24 August 1824, Bremer took possession of the mainland at Port Essington on 20 September, and of Melville and Bathurst Islands on the 26th, planting the settlement on Port Cockburn in the first-named island. For the later history of this settlement see NORTHERN TERRITORY. Bremer's next connection with Australia—he had meanwhile taken part in the Burmese war—was in 1837, when, the Melville Island settlement having been abandoned, he was sent in H.M.S. *Alligator* to make a new one at Port Essington. On this occasion the occupation was deliberately intended to anticipate the French; the earlier reasons had been cancelled by the establishment of a colony on the Swan River. Leaving Port Jackson on 18 September 1838, Bremer reached Port Essington at the end of October, found a good water-supply—the lack of one had been his main reason for not settling there in 1824—and waxed enthusiastic about the fertility of the surrounding region. In the following June he took the *Alligator* back to Port Jackson for supplies: but Gipps, who on 22 July received news of trouble in China, suggested that he should proceed thither at once with the warships then in the harbour. Bremer despatched two, and was preparing to follow in the *Alligator* when news arrived of a serious mutiny among the troops stationed on Norfolk Island. The *Alligator* was therefore diverted to the Island, taking a detachment of another regiment to quell the mutiny; and when Bremer returned the news from China was so reassuring that Gipps thought it unnecessary to send him there, and so allowed him to return early in November to Port Essington. In December, however, he was summoned to India to take over the naval command in those waters, and in 1840-1 commanded a naval expedition to China; then he returned to England, held several important posts in home waters, was made rear-admiral in September 1849, and died on 14 February 1850. (C.B., 1815; K.C.H., 1836; K.C.B., 1841.)

Brennan, LOUIS, born at Castlebar in Ireland on 28 January 1852, educated in Melbourne (where his parents settled in 1862) and trained for civil engineering, in 1874 conceived the idea of a new type of torpedo and spent several years in reducing it to a practical form. The Victorian government gave him £700 towards the expense of experimenting. Sir Andrew Clarke (then inspector-general of fortifications in England) urged the British authorities to adopt it for the defence of harbours and narrow channels, and in 1887 the Imperial government purchased the perfected torpedo for £110,000 and engaged Brennan to superintend the manufacture. In 1896 his position was altered to that of consulting engineer to the factory. About 1907 he was led by his study of the use of gyroscopes in torpedoes to devise a monorail system of traffic in which the vehicles are kept upright on the single rail by the action of a large gyrostat within them. During the war Brennan was attached to the munitions inventions department of the ministry of munitions for confidential research work on aircraft, and has continued his experiments since 1919 under the air ministry. In June 1922 it was announced that a helicopter invented by him had risen to a height of 2000 feet under its own power, carrying a pilot and fuel for an hour's flight; had hovered stationary for half an hour in a 20-mile wind, and then descended vertically with the engine cut out; and had developed a horizontal speed of 60 miles an hour. (C.B., 1892.)

Brewing. See MANUFACTURES.

Bridges, SIR WILLIAM THROSBY (1861-1915), born at Greenock in Scotland on 18 February 1861, and educated at the royal naval school at Greenwich and the Canadian military college at Kingston, came to Sydney after graduation in 1883 and entered the New South Wales roads and bridges department. He volunteered unsuccessfully for the Sudan contingent, but later in 1885 obtained a commission in the colony's permanent artillery (lieutenant, 1885; captain, 1890; major, 1895; lieutenant-colonel, 1902; colonel, 1906; brigadier-general, 1910; major-general, 1914) and was put in charge of the forts on Middle Head, Port Jackson. There in 1893 a school of gunnery was established, and Bridges made chief instructor. Volunteering in 1899 for the South African war, he was attached as major to the artillery of the cavalry division, and saw the relief of Kimberley and the fight at Paardeberg. Invalided home with typhoid, he in 1903 joined the federal headquarters staff as assistant quartermaster-general, and in 1904 acted as deputy adjutant-general and chief staff officer. He had long since gained a reputation for hard work and erudition, and when in the reorganization of the federal defence forces a chief of intelligence was needed (1905-8), or an Australian representative on the Imperial general staff in London (1909-10), Bridges was the obvious man for the work. He returned from London in 1910 to create the military college at Duntroon, and in 1914 succeeded General Kirkpatrick as inspector-general of the Australian military forces.

At the outbreak of the war in 1914 he was entrusted by the Commonwealth government with the organization of an expeditionary force that had been offered for oversea service on 3 August. At once he took a decision of vital importance. The British authorities had suggested a force organized in brigades, such as might be split up among the existing divisions of the British army; Bridges persuaded the Australian minister to offer a complete Australian division, and to hint that its organization had already begun. It was this form of offer, and this only, that made it possible to keep together the Australian troops as a separate entity, destined later on to grow into an army. Expecting to be given command of the troops left in Australia, as was provided in the defence scheme, Bridges recommended that the command of the oversea contingent should be offered to Sir Edward Hutton; but the government decided without hesitation that he himself should take it, and by him it was created, administered, brought into its first campaign, and even named—for the name 'Australian Imperial Force,' perpetuated as 'A.I.F.,' was of his own devising.

The rest of his life was part of A.I.F. history. He took the force to Egypt, trained it there, took it on to Lemnos, planned (in consultation with General Birdwood) the landing, was ashore before 8 a.m. on the memorable 25th of April, being for that day in charge of the two divisions employed at Anzac—the First Australian and the New Zealand and Australian. On 15 May he was mortally wounded by a sniper, and died in the hospital ship on the 19th.

Bridges was not a popular commander, or one who willingly came into contact with his men. But he was a great organizer and administrator in peace and in war, and his remarkable driving power was directed by a no less remarkable intellect, fed with constant study both of books and of men. On his tomb, which tops a hill overlooking the college at Duntroon, the inscription runs:—'A gallant and erudite soldier.' (C.M.G., 1909; K.C.B., 1915.)

Brierly, SIR OSWALD WALTERS (1817-1894), born at Chester in England on 19 May 1817 and grounded in art by Henry Sass (who also trained Millais, Cope, and Frith), studied naval architecture at Plymouth, had two paintings in the Royal Academy of 1839, and in 1841 joined Benjamin Boyd (q.v.) in a cruise to Australia in the *Wanderer,* which left Plymouth on 23 December 1841 and reached Sydney on 18 July 1842. Settling for a time at Boyd Town on Twofold Bay, Brierly acted as manager for Boyd's whaling enterprises. The Melbourne press attributed a large catch of whales in 1845 to his 'superior management.' (The statement in the *Dictionary of National Biography* that he 'settled in Auckland' is a mistake due to the fact that Twofold Bay is in Auckland county, N.S.W.). In 1848 Owen Stanley, then captain of H.M.S. *Rattlesnake,* invited Brierly to accompany him on a voyage of survey N. and NE. of Australia (T. H. Huxley was another passenger); the results of this and a second voyage were some excellent sketches and valuable notes of the places visited, a spirited painting (in crayons and distemper) of the *Rattlesnake* in a squall off Timor, and Brierly's name given to an islet in the Louisiade group—which is now usually called Dadda Hai Island. These trips unsettled Brierly, and as he could not bring himself to return to Boyd Town, he welcomed the offer of Henry Keppel in 1850 to take another cruise among the Pacific islands, joined him in H.M.S. *Maeander,* and in her returned to England in July 1851.

Keppel's friendship made Brierly. He was his guest in the *Maeander* during the Baltic campaign of the Crimean war (1854) and again in the Black Sea (1855), and thus came under the notice of Queen Victoria, who commissioned him to sketch from the royal yacht the naval review which was held at the end of the war. From that time he enjoyed much royal favour; he accompanied the Duke of Edinburgh to Norway in 1863 and round the world in 1867-8—revisiting Australia on that occasion—and on his return was attached to the suite of the Prince of Wales during a tour in the eastern Mediterranean. In 1874 he was appointed marine painter to the Queen and to the Royal Yacht Squadron, and in 1881 curator of the Painted Hall, Greenwich. He died in London on 14 December 1894.

Although praised by Ruskin for his 'faithful and brilliant' drawings, Brierly's work is more valuable as a record than as art. The art gallery of New South Wales has his 'South Sea Whaling off Twofold Bay;' his 'H.M.S. *Galatea* Entering the Heads' is in the possession of the Fairfax family; and there are several in the Mitchell library, Sydney, one of them ('H.M.S. *Black Prince* in a Gale') being probably the best he ever painted. (Kt. Bach., 1885.)

Brigalow. See ACACIA.

Brisbane, capital of the State of Queensland, lies in 27° 28′ S. lat., 153° 2′ E. long., on the Brisbane River, about 12 miles as the crow flies from its mouth in Moreton Bay. The discovery of the river is narrated under EXPLORATION BY LAND. Oxley, who first explored it in 1823 while seeking a site for a new penal

settlement, recommended that a temporary depot should be established at Redcliffe Point (Humpybong) and a permanent township located later on Sea Reach. Accordingly in September 1824 Oxley and Hoddle, with Lieutenant Miller of the 40th regiment, a detachment of his regiment, and a working party of convicts, made a depot at Humpybong. Renewing his examination of the river, Oxley on the 28th landed where is now North Quay and reckoned the place 'a not ineligible site for a settlement:' and, when Governor Brisbane in December brought up Forbes, the chief justice, to inspect the new territory, Oxley's second choice was confirmed, and named Edenglassie by Forbes. This name, however, did not stand. As early as 1825 hospital records use the name 'Brisbane' for the little township, and Darling in 1827 wrote of it as 'Brisbane Town,' but definite official confirmation of the name is lacking until 1839.

Governor Brisbane, eager to relieve Port Macquarie of its convicts, sought at once to establish a regular penal settlement at Edenglassie, but the colonial office was more far-seeing and withheld permission for some time, so that the official proclamation was not made until 15 August 1826. Meanwhile, however, both Brisbane and Darling sent convicts up to erect the necessary buildings and exploit the natural resources of the neighbourhood, Patrick Logan (q.v.), commandant in 1826-30, being especially active in this regard. Darling disliked the site because of the 'tediousness and difficulty of the access,' and in 1827 proposed to make a new settlement on Stradbroke Island, at Dunwich. In 1829 he revived this proposal on the ground that the water-supply at Brisbane was poor and tainted; as an alternative he suggested moving the establishment about six miles downstream, but only the farm was actually so moved. When the penal settlement was officially constituted, 'colonially convicted' prisoners were sent to it—i.e. those who, having been originally transported from England, had committed fresh crimes within the colony—and Port Macquarie was slowly emptied of its convicts. As the Darling Downs began to fill up with squatters' runs, the convict depot was defined by a circle of 50 miles' radius round Brisbane, and entrance from the tableland was strictly prohibited. In 1836 James Backhouse describes Brisbane as consisting entirely of buildings for military or convict use. Relics of those days still exist—the observatory, which was in the thirties a windmill, and the colonial stores building, which dates from 1829. In 1839 measures were taken for the gradual withdrawal of the prisoners; the opening of the district to free settlement was delayed, however, until the receipt, early in 1842, of instructions from England concerning the conditions of land-sales and the application of the money to be derived therefrom. The first landsale in Brisbane was held on 14 July 1842. Captain Wickham, R.N., was appointed the first civil magistrate. But the squatters, now admitted to the Moreton Bay enclave, revived Darling's objection to Brisbane as a port, and demanded a new deep-sea port at Cleveland: Gipps, however, decided to retain the old site, and Brisbane was at last safe. That was a time of commercial optimism, accompanied with much land speculation, and in 1843 town allotments realized up to £250 an acre: in the same year the Hunter River Steam Navigation Company established regular communication between Sydney and Brisbane, a mine being opened near Ipswich to supply their vessels with coal. An area of about 60 miles square, with Brisbane near its eastern side, was proclaimed the county of Stanley and joined with the two nearest coastal counties (Macquarie and Gloucester) to return a member to the New South Wales legislative council. From 1844 onwards there followed a period of depression, due largely to the superior attractions of Port Phillip and the marked neglect of Brisbane by the squatters of the tableland; in 1846 the whole county could only muster 1599 inhabitants. Still, it was in 1846 (on 20 June) that the *Moreton Bay Courier* (now the *Brisbane Courier)* was first issued.

It was at this time that John Dunmore Lang (q.v.) took a hand in remoulding the Moreton Bay settlement. While the Downs squatters were extending their runs towards the coast, and in 1847 obtained an order-in-council declaring all lands 'unsettled' except those within three miles of the coast or ten miles of Ipswich, Lang was in London besieging the colonial office with proposals for a 'Moreton Bay Cotton Company' and a 'Cooksland Colonization Company' to people the land round Brisbane with agriculturists. Finally in 1849, despite the opposition of the colonial office and the total lack of legal authority, he selected about 600 'virtuous Presbyterians' in Scotland and sent them out in three chartered vessels, the *Fortitude* (after which Fortitude Valley is named), the *Chaseley*, and the *Lima*. Cotton, which in his opinion offered the best opportunity for closer settlement, was to be the chief product of these new settlers; but the local administration warned them off as intruders, and the land orders which Lang had provided were found worthless, so that the experiment as its inventor conceived it proved a failure. Still, the arrival in the small settlement of so many industrious and capable Scots certainly accelerated the progress of the district, and by 1851 the population of the county had increased to 8575. In that year the Stanley Boroughs (Brisbane, South Brisbane, Kangaroo Point, and Ipswich) were constituted an electorate for the New South Wales legislative council. On 6 September 1859 Brisbane was incorporated, and the first municipal elections were held on 13 October; late in the year the town became the seat of government of the new colony of Queensland. An old residence built by Andrew Petrie (who arrived in Brisbane in 1837 as engineer and clerk of works) for Dr. Hobbs, one of the Scots selected by Lang, was taken over for the first governor, Sir George Bowen, until a government house was ready in 1862. The old convict barracks, which had been converted into supreme court buildings, were occupied temporarily by the legislature.

Metropolitan improvements followed incorporation. In 1864 work was begun on the Enoggera reservoir at Ithaca Creek to improve the water-supply, which had so far been drawn from a chain of waterholes and sold to the residents by licensed carriers. Work was also begun in 1864 on the Victoria bridge and the town hall. In 1873 the Brisbane-Ipswich railway was commenced, Brisbane being thus linked up with the railway system of the colony, which had previously terminated at Ipswich. The tramways, which were altered from horse to electric power in 1896, were operated by a private company until 31 December 1922 when they were purchased by the Queensland government; the total length of the system when taken over was 42.6 route-miles.

Progress in the arts and education kept pace with industrial development. The Brisbane school of arts, opened in 1851, was used for musical and theatrical productions as well as for public meetings until a permanent theatre was built. The Brisbane grammar school was founded in 1869; in 1871 the Queensland museum was opened; the national art gallery was founded in 1895; the Brisbane library (later the public library of Queensland) was established as a public library in 1896; and in 1909 the university of Queensland was founded. For the formation of a 'Greater Brisbane' controlled by a single municipal council see LOCAL GOVERNMENT.

The population of Brisbane on 31 December 1923 was 235,687, constituting over 29 per cent of the total population of Queensland. G.H.-P.

Brisbane, SIR THOMAS MAKDOUGALL (1773-1860), born at Largs in Ayrshire on 23 July 1773 and educated at the university of Edinburgh, entered the army in 1789 (ensign, 1789; lieutenant, 1792; captain, 1793; major, 1795; lieutenant-colonel, 1800; colonel, 1810; major-general, 1813; lieutenant-general, 1825; general, 1841), and saw service in Flanders (1793-5) and the West Indies (1795-8). But a tropical climate did not suit his health, and, though he served in the West Indies a second time (in 1800-3), he went on half-pay when his regiment was ordered to India in 1805, and retired to Ayrshire to study astronomy. In 1810, however, he was made assistant-adjutant-general, and in 1812 Wellington summoned him to the Peninsula, where he commanded a brigade in Picton's division and saw the series of battles from Vitoria to Toulouse. Having proved himself a sound commander, he was next sent to Canada with his brigade, and took part in the unfortunate fight at Plattsburgh on Lake Champlain; he thus missed Waterloo, but was given a brigade (and afterwards a division) in the British army of occupation in France. In 1818 he returned to Scotland and resumed his scientific studies, but in 1820 was chosen by Bathurst, on the recommendation of Wellington (and apparently of Joseph Banks), to succeed Macquarie as governor of New South Wales. His commission was dated 3 February 1821, and he reached Sydney on 7 November following.

Brisbane's career as governor cannot be called a success. He would have made an excellent governor of a modern self-governing colony; but for a crown colony—especially for one rent with disputes between 'exclusive' and emancipist, and about to enjoy a slight measure of freedom after years of autocracy—he was too peace-loving, too apt to rely on subordinates, too much of an onlooker. Dr. Lang described him as 'a man of the best intentions, but disinclined to business and deficient in energy.' The chief reforms introduced during his term —and they were of great importance—originated either from Bigge's report or from the act (4 Geo. IV cap. 96) which created a constitution for the colony. His own intended reforms were as a rule well designed and useful, but came to little because he could not or would not prevent his officials from thwarting them. Probably the most effective was the limitation of land grants, both in area and by the provision that grantees must employ and maintain one convict for each 100 acres. He also systematized the convict administration, and made it pay by hiring out gangs to settlers for clearing land; abolished censorship of the press (in 1824); reformed the currency, cut down the expense of the commissariat, and made the government farms pay. In accordance with Bigge's reports he made multitudinous changes (he gives in one despatch a list of 157 suggestions that had been carried out), the most valuable of which concerned the segregation of different classes of convicts, educated convicts of good behaviour being usually sent to Bathurst, and the twice-convicted to special penal stations. From this provision, in particular, sprang an activity in coastal exploration that resulted in the discovery of the Brisbane River; the journeys of Hume and Hovell to Port Phillip and of Allan Cunningham to Pandora's Pass also distinguished Brisbane's governorship. Of the constitution which he inaugurated an account is given under CONSTITUTIONS; its essence was that the colony was to be considered no longer a convict settlement, but a colony of free men to be developed by convict labour—as had been Virginia and other early American colonies of Britain. The governor, therefore, while still the final arbiter, was given a consultative council of nominees; if he chose to disregard their advice, he must at once report the matter to London. A supreme court was also set up, and trial by jury allowed in certain cases. The whole system was obviously provisional, and foreshadowed a grant of greater freedom as soon as the settlers had proved themselves fit for it. Immigration was encouraged, especially of young settlers with money, who either developed the districts round Bathurst, Maitland, Goulburn, and Campbelltown, or pioneered the industry later known as 'squatting' by travelling sheep and cattle into the waste lands farther out. As a result the population of the colony increased in 1820-5 from 33,500 to 52,500, though convicts were arriving at the rate of only 1500 a year.

Nearly all Brisbane's measures, original or suggested, were (as has already been said) tainted with the maladministration of his subordinates. Even the notable explorers of his term suffered; Oxley as an 'exclusive' was able to disparage the achievement of Hume and Hovell. The greatest offender, however, was Frederick Goulburn (q.v.), who used to alter the governor's orders and issue others on his own authority, put words into Brisbane's mouth (see PRESBYTERIAN CHURCH), and do many other things that embroiled both himself and the governor with colonists and the colonial office. In 1824 Bathurst settled the trouble by recalling them both. Brisbane left Sydney on 1 December 1825—having prolonged his stay to the utmost in the hope of being able to carry on until Darling arrived. In 1836 he was offered (probably by Wellington) the command in North America, but refused it, and devoted the rest of his life to science, philosophy and agriculture. He died on 27 January 1860 in the room in which he had been born.

Brisbane's astronomical achievements were probably greater than his political doings, and brought him greater notoriety. His observatory at Largs was one of the only two in Scotland; in the Peninsula Wellington declared that he 'kept the time of the army;' when he was first suggested to Bathurst for the New South Wales governorship, Bathurst retorted that he wanted 'a man to govern the earth, not the heavens.' His establishment of the observatory at Parramatta is narrated under ASTRONOMY; for the work done in it Herschel called him 'the founder of Australian science.' Oxford in 1832. Cam-

bridge in 1833, and Edinburgh in 1824 conferred honorary degrees on him; he joined the Royal Society of London in 1810, that of Edinburgh in 1811 (president, 1833-60, succeeding Sir Walter Scott), and the Astronomical Society (vice-president, 1827). (K.C.B., 1814; K.C.H., 1817; baronet, 1836; G.C.B., 1837.)

His cousin, Commodore Sir James Brisbane (1774-1826), was connected with Australia only by his death. During a distinguished career he was Howe's signal midshipman on the 'glorious 1st of June,' 1794, saw the capture of Cape Town in 1795, served under Nelson at Copenhagen in 1801, blockaded the Ionian Islands in 1808, took part in the expedition against Algiers in 1816, and in 1825 (as commander-in-chief on the East Indies station) conducted the naval operations against Rangoon. Leaving Trincomalee on 26 August 1826 in H.M.S. *Warspite*, to take the command on the South American station, he reached Port Jackson on 19 October in a state of great exhaustion, was taken ashore, and died at government house on 19 December. Darling gave him a state funeral. (The statement in the *Dictionary of National Biography* that he died at Penang is an error.)

Bristle-birds and Grass-wrens, dull-coloured perching-birds with long tails that are usually carried erect, belonging to the genera *Sphenura, Diaphorillas* and *Magnamytis*, peculiar to Australia. They are generally regarded as members of the family of warblers (Sylviidae) and are probably near relatives of the Australian wrens (*Malurus*)—perhaps also of the field-wrens (*Calamanthus*), ground-wrens (*Hylacola*) and scrub-wrens (*Sericornis*) but they are a good deal larger than any of these forms. Both

Eastern Bristle-bird.

bristle-birds and grass-wrens are shy birds, frequenting dense thickets, keeping under cover, and darting rapidly across the open spaces between bushes with their tails over their backs. Their nests are dome-shaped structures, composed of grass, with the entrance at the side; they lay two or three eggs, white with brown or reddish spots.

The bristle-birds (*Sphenura*) derive their name from the three pairs of stout bristles that spring from the base of the beak and curve backwards. The Eastern Bristle-bird (*S. brachyptera*) is found—in coastal areas only—in New South Wales and eastern Victoria, and the Western Bristle-bird (*S. longirostris*) in the southern districts of Western Australia. The Rufous Bristle-bird (*S. broadbenti*) occurs on the coastal ranges from Cape Otway in Victoria, to Mount Lofty in South Australia, and also near Cape Geographe, Western Australia. The ten species of grass-wren (*Diaphorillas* and *Magnamytis*) are all confined to the interior, or to the arid regions of the north-west coast. W.B.A.

Bristle-tails. See Thysanura.

Bristle-worms, vernacular name of the Chactopoda, a division of the phylum Annelida —the segmented worms (see Worms). The division comprises the earthworms (q.v.), a number of small worms that live in fresh water, and a vast multitude that live in the sea—for the most part about tidal limits. These last belong almost exclusively to the sub-class Polychaeta (many-bristled worms), as contrasted with the sub-class Oligochaeta (few-bristled worms) which comprises the earthworms and their allies. The Polychaeta include among their numerous Australian representatives a good many conspicuous and familiar objects of the seashore. One of them, found on all extra-tropical coasts where there are tidal rocks, forms thick encrustations of a whitish shelly substance, fully laid bare at low tide. Examined closely, these are found to be composed of twisted calcareous tubes, open at one end, and each lodging a little bristle-worm (*Galeolaria caespitosa*), about an inch or so in length. When out of the water the worms withdraw completely into their tube, the opening being closed with a plug that is armed with spines; when the tide again covers them, each thrusts out the head-end of the body, with the stopper and a crown of plume-like gills.

Besides this widespread, rock-encrusting form (which is also abundant on piles and other submerged timbers), there are many other kinds of tube-dwelling bristle-worms, sometimes growing in masses, sometimes in more isolated fashion, their tubes composed sometimes of hard shelly material like those of *Galeolaria*, sometimes of a flexible membranous substance reinforced with mud or sand, or fragments of broken shells. But these differ little from the corresponding forms in other parts of the world; and no genera are known peculiar to, or specially characteristic of, Australian seas.

The same holds good of the very numerous bristle-worms that are not confined to tubes, but burrow in mud or sand, or creep about among seaweeds and other marine growths. The genera, and sometimes the species, are identical with those occurring in other regions.

Sea-fishermen all over the world use certain species of bristle-worm as bait. In Great Britain, in European countries generally, and in North America the worms mainly used for this purpose are species of *Arenicola*—the 'lug-worms' of Great Britain, which are found burrowing in sand; species of *Arenicola* occur in Australia also—mainly in the south and south-west, and in Tasmania. But on the east coast

the worms used for bait belong to an entirely different group—the family Eunicidae, characterized by the possession of a formidable array of horny jaws. The commonest are species of *Marphysa* (probably *M. novae-hollandiae* of Kinberg) and of *Onuphis* (*O. teres* of Ehlers), large worms, which burrow deeply in the sand about low-water mark. *O. teres* is lured to emerge partly from its burrow with the bait of a piece of meat.

The most important contributions to our knowledge of Australian marine bristle-worms on the systematic side are Augener's two papers in *Die Fauna Südwest Australiens*, vols. IV. and V. (Jena, 1913, 1914). W.A.H.

Brittle Bladder-fern. See FERNS.

Broken Bay, an arm of the sea which forms the estuary of the Hawkesbury River on the coast of New South Wales; near the mouth it has two branches, the long and narrow Pitt Water to the south, and to the north Brisbane Water, with a narrower and shallower entrance but expanding into a broad bay. The bay and its branches were discovered on 2 March 1788 by Phillip, who described Pitt Water as 'the finest piece of water I ever saw.' On that occasion he did not find out that he was entering an estuary: it was only on 10 June 1789 that he penetrated beyond Lion Island, and only on the 12th that he knew he was rowing up a river.

At half-past-five in the afternoon of 7 May 1770 Cook noted in his log 'some broken land like a bay N. 40° W.,' and it was in search of this that Phillip lighted upon Broken Bay and so named it. The difficulty is that Phillip was looking for a bay 'about eight miles to the northward of Port Jackson,' while the mouth of Broken Bay is nearly twice as far north. Phillip did not comment on this discrepancy, but Flinders in his *Voyage to Terra Australis* (ii. 2) called attention to it, and suggested that Cook's 'broken land' was in the neighbourhood of Narrabeen lagoon. (Flinders as usual took his Cook quotations from Hawkesworth—not always a safe authority.) Now the position stated in the log—a bearing of N. 40° W. at a moment when the *Endeavour* was about 8 miles off shore and 9½ miles north of Port Jackson—coincides with that of Barranjuey Head at the mouth of Broken Bay; but Cook's chart, for reasons unknown, shows the name 'Broken Bay' quite six miles to the south, near Narrabeen lagoon. The chart and Hawkesworth cannot be reconciled with the log—and there the matter rests. F.J.B.

Broken Hill, an important mining city in Yancowinna county, New South Wales, situated in the Barrier Ranges about 1000 feet above sea-level, and 35 miles from the South Australian border. Commercially and geographically it is closely associated with South Australia, being connected by rail with Port Pirie (which is its natural port, and where large smelters have been erected) 254 miles away, and with Adelaide, 335 miles away. Direct railway connection with Sydney is under construction; this line will be 703 miles in length. The climate of Broken Hill is arid; its average annual rainfall is about 9 inches, and the annual evaporation about 7ft. 6in. Heavy dust-storms are common. The summer shade temperature frequently passes 100° Fahr., and 112° and 115° have been reached. In winter it is cool, and frosts are experienced. The mean temperature is 65.5°. For a few miles round the town the vegetation was cleared off by residents in the early mining days, and has not regrown—except for certain grasses and herbs which appear for a short time after rain. The original hills were covered with mulga scrub, and the flats grow mainly bluebush and annual saltbush. The creeks, which at ordinary times are beds of sand, are generally marked with a line of gum-trees on each bank.

Early History.—The Barrier Ranges, which have a summit level of about 1400 feet, were discovered by Sturt in 1844. They consist of ancient contorted sedimentary rocks, intruded by granite, diorite, etc., and are traversed by numerous white quartz reefs. In 1867 reports of these conspicuous outcrops caused a rush from South Australia in search of gold. It ended in disaster, the prospectors encountering great difficulties from lack of water without discovering gold; other minerals were not looked for, and the rich deposits of silver ore were unrecognized. The first recorded discovery of silver-lead ore was made in 1876 by P. Green at Thackaringa, 20 miles from Broken Hill. From his mine 36 tons of ore were carted 210 miles to Burra Burra, railed to Adelaide, and shipped to England—to be jettisoned on the voyage. In 1880 another lot was shipped from the same mine, and reached England safely. In 1882 a rush was made to Thackaringa and Umberumberka, and a number of mining leases were taken up. In 1883 the township of Silverton was surveyed, over 5000 acres were applied for as mining leases, and small quantities of extraordinarily rich silver ore were obtained from a number of shallow narrow lodes. They consisted mainly of chloride of silver, and assayed in some cases as high as 10,000 (even 18,000) oz. of silver to the ton. Larger lodes of silver-lead ores (mainly galena), but of lower values, were also worked in the Umberumberka, Pinnacles, Daydream, Thackaringa, and other mines. In September 1883 a boundary rider named Charles Rasp, employed on Mount Gipps station, pegged out 40 acres of great iron-stone outcrop as a tin mine. A syndicate of seven, each of whom contributed £70, was then formed, including George McCulloch, manager of the station, and six more blocks of 40 acres were applied for. This syndicate was generally laughed at, but it persevered and sunk a shaft called 'Rasp's shaft' in which, towards the end of 1884, chloride of silver was struck at a depth of about 100 feet. Rich ore was discovered on other parts of the property soon after, and on 10 August 1885 the Broken Hill Proprietary Co. was floated. No tin was found. Two or three years later the Block 10, Block 14, and British Companies were floated off the parent company, which only retained three of the original seven blocks. Other companies were formed to N. and S., the main ore bodies, as since developed, extending over a distance of about three miles.

In 1885 blast furnaces were erected at the Pinnacles and Daydream mines, and in 1886 at Broken Hill. In 1887 the Silverton Tramway Co. opened a railway line from Broken Hill through Silverton to Cockburn, where it junctioned with the South Australian railways. Silverton now began to decline rapidly in favour of Broken Hill (named by the government Willyama). The town grew by leaps and bounds, and in 1889 its population reached 17,000. The rapidity of growth is perhaps best shown by the value of its yearly mineral output, which in 1885 was £108,281, in 1888 £1,001,848, and in 1891 £3,529,043.

Modern Development.—The city of Broken Hill, as regards population, ranks third in New South Wales, yielding place only to Sydney and

Newcastle. Its population at the 1911 census was 30,972, and in 1914 must have exceeded 35,000, since when it has fallen again to 26,337 (1921 census). It possesses substantial public buildings, a post office, town hall, theatres, a technical college, libraries, and a well-equipped hospital. Steam trams run to the suburbs, and there are good gas, electric light, and water services. For the water-supply two large dams have been constructed, one (completed in 1892, of 3940 million gallons capacity) at Stephen's Creek, ten miles away, the other (completed in 1915, of 2903 million gallons capacity) at Umberumberka Creek, 19 miles away.

The value of its mineral output to the end of 1924 was approximately 121 millions sterling, and the dividends paid by the mining companies were approximately 28 millions. The quantity of ore extracted totalled 34 million tons, the maximum output for one year (1913) being 1,744,177 tons. The ore developed and available for extraction was estimated by the government geologist in May 1925 at over 13 million tons, with unknown possibilities beyond.

Ore Treatment.—Methods of treating the Broken Hill ores have varied with the class of ore. When the mines were first opened up, the ores to be dealt with were (*a*) very rich silver ores (native silver and chlorides, iodides, etc., principally in kaolin) and (*b*) oxidized lead ores (carbonates, etc.) which were either rich enough for shipment or were smelted at the Hill to produce argentiferous lead. The lead ores, which carried high silver values and practically no zinc, were smelted direct in blast-furnaces at the Hill or elsewhere; the silver ores, containing high silver values but very little lead or zinc, were roasted, chloridized and leached. These methods, however, have not been practised for many years. The silver-lead bullion obtained from the smelters was sent to Port Pirie in South Australia for refining and separation of the metals. Later on, as it was found more economical to smelt on the seaboard, where fuel and fluxes were easily available, large lead blast-furnaces were erected at Port Pirie. As the mine-workings went deeper, and farther away from the original blocks of the Proprietary Company, the ores changed to sulphides of lead and zinc (galena and blende), carrying lower silver values. The main ore body now consists of fine-grained lead-silver-zinc sulphides, and the treatment of it is practically uniform throughout the field. At first the concentration of the ores was confined to the saving of the lead, (and with it a large proportion of the silver), the zinc largely remaining in the residues. Big dumps, aggregating millions of tons of these residues, accumulated on the surface, and quantities were used as filling for the underground workings. The difficulty was that the blende (sulphide of zinc) did not differ sufficiently in specific gravity from the worthless minerals (gangue) to allow of its separation by the ordinary methods of wet concentration. In time, however, an entirely new process was evolved to meet the case the 'Flotation' process, which has been developed by Elmore, Delprat, Potter, DeBavay and others—and by its means the big dumps of zinc residues, as well as the current production of residues from the lead concentrating mills, became a valuable asset. Zinc concentrates were made on a large scale and shipped for further treatment mainly to Belgian and German smelters, where metallic zinc (spelter) was obtained from them; a comparatively small proportion of these concentrates was treated at the Proprietary Company's own zinc distillation furnaces at Port Pirie. The war put an end to oversea shipment to foreign countries, and smelting and refining is now done at Port Pirie, at Hobart (see HYDRO-ELECTRIC DEVELOPMENTS), and in England.

At present the method of concentration is practically identical throughout the field, with minor variations by individual mines. The mixed lead-zinc sulphide ore is first crushed to pass ½-inch holes and jigged to recover the galena concentrates. The residue from the jigging is ground to pass screens having 30 holes to the lineal inch, giving a product suitable for treatment on concentrating tables (Wilfley, etc.) to get galena concentrates. The residue from the Wilfley tables, together with the slimy product produced in crushing and grinding, are treated either together or individually by a flotation process to yield galena concentrates, blende concentrates, and comparatively barren residues.

The galena concentrate assays approximately —lead, 60 per cent; silver, 30 oz. per ton; zinc, 10 per cent. The blende concentrate assays—lead 7 per cent; silver 10 oz. per ton; zinc 47 per cent. The combined recoveries of the metals range from 85 to 90 per cent. The galena concentrate at present is wholly smelted at the works of the Broken Hill Associated Smelters, Port Pirie; the blende concentrate is partly treated by the Electrolytic Zinc Company at Hobart, and partly sold overseas. The barren residues from the concentrating mills are used for underground filling or stacked on the surface. Standard types of ore-breakers, crushing rolls, jigs, concentrating tables and general concentrating accessories are used throughout the field. For the flotation process, the Mineral Separation Company's patents and machines are used for the general work, and the Bradford flotation process for special selective work. The sulphuric acid required in the flotation plants is made partly in brimstone-burning contact and chamber acid plants, and partly in chamber acid plants operating on SO_2 gas, obtained by roasting blende concentrates in furnaces of the de Spirlet type. Modern power plants, containing 3500 kilowatt A. C. generators, supply power to the bigger mines, and the water-supply for concentrating purposes is drawn partly from underground drainage in the mines, partly from the government reservoirs at Stephen's Creek and Umberumberka.

For other enterprises carried on by the Broken Hill Proprietary Company see IRON AND STEEL.

J.F.S.

Brolga. See NATIVE COMPANION.

Bromby, CHARLES HENRY (1814-1907), was born at Hull on 11 July 1814, and educated at Uppingham school and St. John's College, Cambridge (B.A., 1837; M.A., 1840; D.D. (hon.), 1864). He was ordained deacon in 1838 and priest next year, but after a short period of parochial work settled down as a schoolmaster. From 1841-3 he was head of the Stepney grammar school, and then until 1864 principal of the Cheltenham training college for school instructors. In that year he was appointed by letters patent under the Crown (the last time that process was used for colonial bishoprics) bishop of Tasmania, and enthroned in St. David's Church, Hobart, on 7 January 1865. After the disestablishment of the Anglican Church in Tasmania he organized its finances skilfully, procured local legislation that ensured the creation of a diocesan fund, had St. David's consecrated in 1874 as the diocesan cathedral, and took an

active share in the formation of a general Anglican synod for Australia and Tasmania. He resigned his bishopric in 1882, proceeded to England, and spent the next 15 years in assisting the bishops of Lichfield (1882-91) and Bath and Wells (1891-7). He died at Clifton in 1907.

His second son, CHARLES HAMILTON BROMBY (1843-1904), was Tasmanian attorney-general from 1876 to 1878.

Brooke, GUSTAVUS VAUCHAN (1818-1866) born in Dublin on 25 April 1818 and educated by a brother of Maria Edgeworth, was intended for the bar; but a visit of W. C. Macready to Dublin fired him (at 14) with an ambition for the stage, and he presented himself to the manager of the Dublin theatre, who took his address and forgot all about him. Some months later Edmund Kean failed to keep a Dublin engagement, and the manager engaged Brooke to fill the gap. His first appearance was made on an Easter Monday (9 April 1833), and permanent employment followed. He made his first appearance in London as Virginius at the Victoria theatre, but attracted little attention; his real debut was as Othello at the Olympic on 3 January 1848, when he scored a success, and followed it up with a series of Shakespearean performances. In 1851 he visited the United States, and in 1854 met George Coppin (q.v.), and entered into an engagement for 200 nights in Australia; he sailed for Melbourne in September 1854, appeared first at the Queen's theatre, Melbourne, as Othello, and during his visit played in every established theatre and in many that were run up specially for him on the goldfields. The engagement with Coppin merged into a partnership which owned the Melbourne Olympic, Theatre Royal, and Cremorne Gardens; when the partnership was dissolved, the Theatre Royal fell to Brooke, but he was no manager, and his venture proved disastrous. He returned to England in 1861, but was not very successful, the taste of theatre-goers having changed. Consequently, in 1865 Coppin again made arrangements for an Australian visit, and Brooke left England in the *London* on 30 December. On 11 January 1866 the vessel foundered, and Brooke, who had worked incessantly at the pumps, refused a seat in the engineers' boat, only sending a message of farewell to the people of Melbourne. He was sincerely mourned in Melbourne, and pressmen obtained a bust of him by Summers, which is now in the art gallery.

Brooklime. See SCROPHULARIACEAE.

Broome, SIR FREDERICK NAPIER (1842-1896), born in Canada on 18 November 1842, was the eldest son of Frederick Broome, missionary (afterwards rector of a Shropshire parish). He was educated at the grammar school in Whitchurch, Salop, migrated to Canterbury, New Zealand, in 1857 to become a pastoralist, but in 1869 returned to England and took up journalism, mainly for *The Times*. Going to Natal with Sir Garnet Wolseley in 1875 he became successively colonial secretary of that colony, colonial secretary of the Mauritius, and lieutenant-governor of the same. In 1882 he was appointed governor of Western Australia, then still a crown colony, so that he was able to exercise a good deal of influence on its welfare. His governorship was marked (*a*) by a rapid extension of railways and other means of communication, (*b*) by an agitation for the grant of responsible government, which he thoroughly approved of and did his best to forward—going to England in 1889 with a deputation, and materially helping to secure it. When in 1890 the colony obtained a constitution, his term of office there ended, and he was transferred as acting governor to Barbados, becoming next year governor of Trinidad. He died in London in 1896.

He published in 1868 and 1869 two volumes of poems, and did much writing for the *Cornhill* and *Macmillan's Magazine*. (C.M.G., 1877; K.C.M.G., 1884.)

His wife, Mary Ann Lady Broome, whom he married in 1864, was daughter of W. G. Stewart, colonial secretary of Jamaica. In 1852 she married Sir G. R. Barker, K.C.B., who died in 1860 at Simla in India. Broome being at the time of the 1864 marriage still un-titled, she retained the name 'Lady Barker' for many years, and under it published in 1870 *Station Life in New Zealand*, based on her experiences in 1864-9. *A Year's Housekeeping in Natal* (1877) followed on Broome's term of office in that colony, and *Letters to Guy* (1885) on his work in Western Australia. She died in London on 6 March 1911.

Broughton, WILLIAM GRANT (1788-1853), born in Westminster on 22 May 1788 and educated at Barnet grammar school and the King's School, Canterbury, was from 1807 to 1812 a clerk in the East India House. His personal aim, however, was to enter the Church of England ministry, and in 1814 he abandoned commerce, entered Pembroke Hall, Cambridge (B.A. and 6th wrangler, 1818; M.A., 1823; B.D. and D.D., 1836), was ordained deacon in 1818 and priest later in the same year, and until 1827 was curate of Hartley Wespall in Hampshire. This village was adjacent to the Duke of Wellington's estate of Strathfieldsaye, and in October 1828 Broughton (after a short term at Farnham) was made by the Duke chaplain at the Tower of London. Scarcely, however, had he accepted this appointment than the Duke urged him to take up the office of archdeacon in New South Wales in succession to T. H. Scott (q.v.). To this post he was formally appointed on 6 February 1829, and, reaching Sydney on 13 September, was on the 17th made a member of the legislative and executive councils. Darling, whose respect for church dignitaries almost invariably mastered his naturally quarrelsome temper, promptly recognized his zeal and value as an adviser, and not long before he resigned the governorship described Broughton as 'remarkably clear in his views, cool and dispassionate, and possessing a sound judgment.' In 1834 Broughton visited England to lay before ecclesiastical and missionary bodies the needs of Australia as regarded both suitable clergy and funds for churches and schools. Bourke had already (in September 1833) proposed to the colonial office that the archdeaconry should be made at least a bishopric suffragan to Canterbury or London—at the time it was attached to Calcutta. Consequently, one result of Broughton's campaign in England was the establishment of an independent bishopric of Australia, and his appointment to the new see with the unqualified approval of all concerned. He was consecrated on 14 February 1836, arrived in Sydney on 2 June, and on the 5th was installed during a service that lasted 5½ hours.

Broughton's term as bishop, no less than his earlier term as archdeacon, was filled with arduous supervision of his huge diocese, involving many thousand miles of travel yearly. As archdeacon he had charge of eastern Australia (to 129° E. long.), Tasmania and Norfolk Island: as bishop the whole continent and the two islands were within his jurisdiction. He was proud of his Church, and very jealous of her status in the

new colony, and on several occasions (e.g. when in Bourke's instructions the archdeacon's precedence was slightly lowered) resented what he thought were attempts to diminish her prestige. This attitude very nearly lost him the bishopric: for Bourke had coupled with his proposals for a bishopric further proposals for state support to Roman Catholics and Presbyterians, and Broughton explicitly refused to concur in a system that might 'attach men more to the errors of their Church and check the progress of the Reformation.' The colonial office, however, assured him that its offer was unconditional, and left him free to oppose or support any policy he chose. At the same time he was placed in a somewhat invidious position, since as bishop he was a member of the executive and legislative councils, and thus had an influence on legislation and governmental policy which was denied to the heads of other denominations. This was especially marked in the sphere of education. When the clergy and school lands corporation was dissolved in 1833, Bourke proposed not only state subsidies for the three principal denominations but the abolition of state aid for denominational schools and the provision of public schools for all children. Broughton told him that, though a state might tolerate several religions, it should aid only that which it believed to be the true religion; he also actively opposed the establishment of public schools, and forced Bourke to protest to the colonial office against his membership of the two councils. As Bourke foresaw, this attitude of its head roused ill-feeling against the Church of England among the other denominations, and to that extent Broughton's episcopate harmed his Church, but within it his work was unceasing and of great value. In 1847 his huge diocese was subdivided by the creation of sees at Newcastle, Melbourne, and Adelaide—Tasmania had already become a separate diocese in 1842; thenceforth Broughton's title was bishop of Sydney and metropolitan of Australasia. In 1852 Broughton again visited England to lay before English Churchmen the state of the Church in Australia, particularly in connection with the gold rush. Age, overwork, and an illness contracted on the voyage, shattered his constitution, and he died in London on 20 February 1853.

Brown. GEORGE (1835-1917), was born at Barnard Castle in Durham on 7 December 1835 and while a boy trained in a local surgery, was afterwards apprenticed to a draper, whom he soon deserted for love of the sea. After some short voyages he sailed to Quebec, and there left his ship to work in a general store at New London. Five years later he was back in England, but could not settle to any business, and his father agreed to send him to his uncle (Thomas Buddle, Wesleyan missionary) in New Zealand, on the understanding that he went as a passenger and not before the mast. In March 1855, therefore, Brown sailed in the *Duke of Portland*, with Bishop Selwyn and J. C. Patteson (afterwards Bishop of Melanesia) as fellow passengers, and lived with his uncle at Onehunga till 1860, when he was accepted for mission work, designated for Samoa, and ordained in the Centenary Chapel at Sydney. He reached Samoa on 30 October 1860, remained there for 14 years, and then moved to New Britain, where he founded a mission and superintended it for seven years. In New Britain Brown found himself suddenly in circumstances of unparalleled difficulty; four of his teachers were murdered and eaten, and the life of every white person on the islands was threatened. The white residents urged on him an active defence; he agreed, and the actual perpetrators of the murders were punished with their accomplices. Brown's share in this act of defence was severely criticized, chiefly by those at a distance who were not in possession of the facts; but Captain Purvis, who was instructed to make a full enquiry into Brown's action, reported: 'I therefore think Mr. Brown, having regard for the safety of those people entrusted to his care, could hardly have acted otherwise.' In 1881 he returned to Sydney, and in 1887 was appointed general secretary to the board of missions, a post he filled for the next 21 years. The same year he was a member of the deputation sent to Tonga by the Wesleyan conference in connection with the Shirley Baker dispute, and in the following year he again visited the group as a commissioner to report upon the best means of securing reunion with the Tongan Free Church; a third visit was paid in 1889. In May 1891 Brown founded a Wesleyan mission in New Guinea, and in May 1902 led a pioneer mission party to the Solomon Islands, after visiting both New Guinea and the Solomons in order to make preliminary enquiries. In 1891 he was elected president of the New South Wales conference, and in 1913 president of the Australasian conference. In 1908 he was placed on the supernumerary list, and died on 7 April 1917 at the age of 82, having been a minister for 58 years.

Outside his ministerial work he was an ardent anthropologist, and contributed many scientific papers to the proceedings of learned societies. In 1908 he published an autobiography, *George Brown, Pioneer Missionary and Explorer*, and in 1910 *Melanesians and Polynesians*, which he had written in 1887 for the journal of the Anthropological Institute. His collection of island curios and natural history specimens is in the Bowes museum at Barnard Castle. Personally he was one of a notable band of missionaries (including Fison and Chalmers) who without neglecting their mission work achieved results of great scientific and political value in the South Pacific. Robert Louis Stevenson volunteered unavailingly to write the story of his life, and described him in glowing terms as a man 'with no humbug, plenty of courage and the love of adventure.'

J.C.

Brown. ROBERT (1773-1858), born at Montrose in Scotland on 21 December 1773 and educated at Marischal College, Aberdeen, studied medicine at the university of Edinburgh and in 1795 joined the army as a surgeon; but his love of botanical research had mastered him while still a student, and his military career was short. On 12 December 1800 Sir Joseph Banks, with whom he had corresponded on botanical subjects, offered him the position of naturalist aboard the *Investigator*, in which Flinders (q.v.) was to explore the coasts of Australia. Brown accepted the offer—which included a condition that all memoranda, sketches or collections he might make during the voyage were the property of the admiralty, a share of the profits (if any) obtained from publication of them being reserved for Brown. Accordingly, when in June 1803 the *Investigator* was condemned and Flinders left for England in the *Porpoise*, he took a large part of Brown's collections with him, and it was lost (except a few boxes of seeds) when the *Porpoise* was wrecked. Brown himself and his

draughtsman Ferdinand Bauer remained in Australia until 1805, visiting the islands in Bass Strait, the Tasmanian settlements at Port Dalrymple and Hobart, and the valleys of the Hawkesbury, Hunter and Williams. He reached England again on 12 October 1805 in the *Investigator*, which had been patched up to make the voyage. From 1806 to 1810 he was engaged in working up the material he had accumulated in Australia, and in 1810 published his *Prodromus Florae Novae Hollandiae*, which Hooker described as 'the greatest botanical work that has ever appeared.' Brown then succeeded Dryander as librarian to Sir Joseph Banks, and on Banks's death inherited his herbarium and library, with remainder to the British Museum; within a few years he decided to transfer the collections to the museum at once, and in 1827 became keeper of the museum's botanical department. In 1835 his official title was altered to 'Keeper of the Banksian Botanical Collections and Under-librarian of the Museum.' He died on 10 June 1858.

Of Brown's value both to Australian botany and to the science of botany in general it would be hard to say too much. Hooker, whose eulogy of the *Prodromus* has already been quoted, said that Brown himself 'united a thorough knowledge of the botany of his day with excellent powers of observation, consummate sagacity, an unerring memory, and indefatigable zeal and industry as a collector and investigator.' Humboldt called him '*botanicorum facile princeps*,' and Asa Gray said 'No naturalist ever taught so much in writing so little, or made so few statements that had to be recalled, or even recast.' These praises, however, came to him late in life or posthumously. The *Prodromus* itself remains a fragment, lacking beginning and end, because the sales were so small—Brown withdrew it from sale in 1816, when only 26 copies had been disposed of. He revised it for a German edition published at Nuremberg in 1827, and in 1830 published a small *Supplement* describing some new Proteaceae; but the *Prodromus* as originally conceived was never completed. He also wrote botanical appendices for Flinders's *Voyage to Terra Australis* (1814) and Sturt's *Narrative of an Expedition into Central Australia* (1849). His minor miscellaneous works were collected and edited for the Ray Society by J. J. Bennett in 1866-7. The Linnean Society, of which he became an associate in 1798, made him a fellow in 1822 and its president in 1849-53; the Royal Society made him a fellow in 1811; Oxford gave him an honorary D.C.L., Cambridge an LL.D., and Prussia a knighthood of the order Pour la Mérite. An appreciative account of his work is given in Maiden's *Sir Joseph Banks*, pp. 100-123.

Browne. THOMAS ALEXANDER (1826-1915), son of Sylvester John Browne of the East India Company's service, was born in London on 6 August 1826, brought to Australia by his parents in 1830, and educated at the Sydney College under W. T. Cape (q.v.). At the age of 17 he entered on station life in western Victoria, and from 1844 to 1856 was the owner of Squattlesea Mere in the Port Fairy district; he then purchased stations on the Murray (1858) and Murrumbidgee (1864), but lost heavily in the droughts of 1866 and 1869, and abandoned squatting in 1870 to become a few years later police-magistrate and goldfields-warden at Gulgong in New South Wales In 1887 he was transferred to Albury, and retired from the public service in 1895. From 1870 onwards, using the *nom de plume* 'Rolf Boldrewood,' he wrote stories of squatting life, one of which (*Ups and Downs*) was published in London in 1878; and *Old Melbourne Memories*, a collection of sketches of early pastoral days in the 'Western District'—possibly the most valuable work he did—was published in Melbourne in 1884. But his first success as a novelist—and the one by which he is still most widely known—was *Robbery Under Arms*, published in 1888, a piece of effective melodrama constructed round the many (mainly true) stories of Australian bushrangers; this he followed up in 1890 with *The Miner's Right*, a tale of the goldfields in which his experiences at Gulgong were fully drawn on. Other novels (many of which had been written long before and published serially) followed at the rate of one a year until 1906, but the pattern was too similar in all to let any stand out as the first two had done. He died in Melbourne on 11 March 1915.

Rolf Boldrewood's work, while it cannot be classed high as literature, has been in many ways extremely valuable to Australia. Contrasted with the pessimism of Gordon, the melancholy of Kendall, the morbidity of Marcus Clarke—the three writers by whose work Australia was until quite recently known to the outside world—his eager and virile romanticism, the reflection of a manly and generous nature, helped to stimulate a belief in the country among both Australians and readers overseas. His plots are often confused and sometimes jejune; his character-drawing, in regard to his principal characters, is unconvincing; the aspirations of his hero and heroine to end their lives in England class him with Gordon and Kingsley rather than with genuinely Australian authors. But in his gallery of well-studied minor characters he has embodied much of the real bush life of Australia; and the fine adventurous gallantry which he exalted, and so obviously loved, is a virtue proper to manly youth all the world over.

Browne. SIR THOMAS GORE (1807-1887), son of Robert Browne and brother of a well-known bishop of Ely and Winchester, was born on 3 July 1807, and entered the army in 1824 as ensign (lieutenant, 1826; captain, 1829; major, 1834; brevet lieutenant-colonel, 1842). In the first Afghan war (1842) he commanded a regiment and saw much fighting. During the early thirties he had been colonial secretary in the Ionian Islands, and in 1851 reverted to this type of work, becoming governor of St. Helena (with the rank of colonel) in that year and governor of New Zealand in 1854. His term of office there was troubled by a native war, partly due to his unsympathetic treatment of Maori claims in regard to land customs. The 'King' movement, intended to band the Maoris together and give the tribes a single head who could negotiate on equal terms with the English governor, originated in his time. In 1861 he was replaced by Sir George Grey (q.v.), and transferred to Tasmania; leaving in 1869, he administered Bermuda for nine months in 1870-1, and then retired. He died on 17 April 1887. (C.B., 1843; K.C.M.G., 1869.)

Bruce. GEORGE (1778-1819), born at Shadwell in London and while still a child employed in a rope factory, soon escaped parental control, was consigned to the Shadwell workhouse, and from that institution apprenticed to a North Sea fishing-smack. He deserted, became pot-boy at an inn, entered on a career of petty thieving,

and in 1791 was sentenced to death for breaking a window and stealing two handkerchiefs. This sentence being commuted to one of transportation on account of his youth, he was sent to Port Jackson in the transport *Royal Admiral* and reached Sydney on 7 October 1792. He was even then only 14 years old, and the authorities employed him to help George Caley (q.v.) in collecting insects, then as personal servant to a convict superintendent, then as servant to Grose, at that time lieutenant-governor in charge of the colony. Grose gave him a free pardon, and he went back to sea in the *Cumberland* (a 29-ton schooner), was one of the crew during her survey work in Bass Strait in 1802, and left her when Flinders took her over in September 1803. He then joined the local police, but for misbehaviour was dismissed and imprisoned, for joining in a fight was sentenced to 200 lashes, and to avoid this punishment absconded into the bush; five months of danger and misery drove him back to the settlement, and in the end King (who needed experienced sailors) pardoned him and sent him to join the *Francis*, and when she was wrecked to the *Lady Nelson*. In February 1806 this vessel was employed to take a Maori chief, Te Pehi (usually known as Tippahee), back from Sydney to his territory on the Bay of Islands. Te Pehi being taken ill during the voyage, Bruce was set to nurse him, and made himself so useful that the chief gained permission to keep him. He thus became the first Englishman to reside among the Maoris. After seven months he was tattooed, made a chief, and given Te Pehi's youngest daughter for a wife.

During his two years' stay at the Bay Bruce aided several British vessels to obtain cargoes; but in 1808 the master of a passing vessel, the *General Wellesley*, enticed him and his wife aboard, took them to Fiji and thence to Malacca, and when compelled to let Bruce land there went off by night with the Maori girl to Penang, and there disposed of her to a Captain Ross. Following her up in H.M.S. *Scourge*, whose captain stood his friend, Bruce recovered his wife after three months, was taken on to Calcutta, and from that port by the intervention of the governor-general (Lord Minto) obtained passage back to New Zealand in the *Union*. This vessel, however, had to put in at Hobart during June 1809, and Bligh (who was lying in Storm Bay aboard H.M.S. *Porpoise*, and could get no provisions from the shore) commandeered her stores; before she could replace them Macquarie ordered all vessels to Port Jackson, and the *Union* hurriedly landed her passengers there on 17 January 1810 and by the 8th of March was on her way back to Calcutta. Bruce at once appealed to Macquarie for a passage to the Bay of Islands, and arranged with a syndicate (which included Simeon Lord) to be their agent there; before he could sail, his wife died, and news came from New Zealand that Te Pehi had treacherously murdered the crew of a British trading vessel, the *Boyd* (see NEW ZEALAND). The massacre was a fact, but Te Pehi had taken no part in it except to rescue four members of the *Boyd's* company; still, it put an end to any immediate prospect of return to New Zealand, and Bruce (who after his wife's death was not so anxious to return) shipped aboard the *Porpoise*, went back to England, and enlisted in the navy. In 1813 he memorialized Earl Bathurst in the hope of procuring a passage back to New Zealand. But his confused and unreliable story drove Macquarie (to whom it was referred) into angry contradiction and an account of Bruce's life that was just as unreliable; his petition was refused, he grew prematurely old and decrepit, was admitted into Greenwich hospital on 18 April 1817, and died there on 9 February 1819. His manuscript diary, dictated while at the hospital to fellow-pensioners and left there after his death, is in the Mitchell Library at Sydney.

Brush Turkey. See MOUND-BIRDS.

Bryant, WILLIAM, a West-of-England fisherman who was transported in the First Fleet for 'having interrupted revenue officers in the execution of their duty'—i.e. for assisting smugglers—was employed by Phillip to superintend the fleet of fishing-boats which in the early years of the colony provided settlers with a large proportion of their food. According to Collins, 'every encouragement was held out to this man to keep him above temptation . . . . but he was detected in secreting and selling large quantities of fish;' in 1789 he was punished severely, but was too valuable an expert to be deprived of his job, and for two years longer continued to run the fishing fleet. On 28 March 1791, however, at the moment when according to his own statement his sentence was on the point of expiry, he with his wife and two infant children and seven other convicts put to sea in a fishing-boat. The names and sentences of these convicts are worth recording. Bryant's wife had been sentenced to death for stealing a cloak, but given seven years at Botany Bay in lieu of hanging; she had still two years to serve when she escaped. Cox, Allen, and Lilley had life sentences, Allen for stealing handkerchiefs, Lilley for stealing a fish-net, a watch and two spoons. Bird and Martin had still a year to serve out of a seven-year sentence; the latter had been convicted of stealing 20 lb. of old lead and iron. Of Morton, who died on the way home, we know only that he was a seven-year convict with five years still to go, and that he knew something of navigation. The seventh man is rather a mystery; Collins calls him 'Samuel Broom;' at a later trial he was 'John Butcher,' a man 50 years old who had been given seven years for stealing three pigs. (For that matter Samuel Bird was known in Timor as John Simms, though he was Bird again before he died.) Of the nine adults, therefore, one was almost or actually free and three others had but a short time to serve; but, as they explained later, starvation was what they feared and ran away from. These details, though scarcely relevant to the story of Bryant's escape, serve to illuminate the conditions under which at the end of the eighteenth century transportation was carried on.

The escapees' boat was in good condition and provisioned with flour, rice, pork, and a ten-gallon keg of water; Bryant had also bought from the master of a Dutch vessel then in port a chart, quadrant, and compass, and had obtained from him a good deal of useful information about course and currents. The boat was steered northwards along the coast, with a view of reaching Timor. For five weeks it rained continually, and fear of hostile blacks prevented the party from landing often. From their description of one resting-place it has been identified as Port Macquarie. Until they reached the Gulf of Carpentaria the natives they saw differed little from those with whom they were familiar near Sydney, but in the Gulf they were chased by large sailing proas (probably Malay) and barely escaped capture by pulling hastily to windward. Reaching Kupang in Timor on 5 June,

they pretended to be refugees from an English vessel that had foundered on her passage between India and New South Wales. The Dutch treated them with great kindness, but their behaviour after a time roused suspicion, and some of them when in drink betrayed the secret. During September Captain Edwards of the *Pandora*—which had been wrecked in Torres Straits on 29 August (see BOUNTY, MUTINY OF THE)—reached Timor in an open boat, and on 5 October the escapees were handed over to him. He took them to Batavia, where Bryant and one child died in hospital; then in a Dutch vessel to the Cape of Good Hope, Cox (who fell overboard), Bird (Simms), and Morton dying on the way; at the Cape he handed them over to Captain Parker of the *Gorgon*, and in her they reached England with the loss of Bryant's second child. The survivors were tried over again at the Bow-street police court in July 1792, and declared they would rather be hanged than sent back to the colony; but in the end Mary Bryant (after being visited in Newgate by 'a gentleman of high rank in the army') was pardoned, and Allen and Lilley, being 'lifers,' were sent back to undergo their sentence. Butcher had an easier fate. On 23 January 1793 he wrote from Newgate to Henry Dundas—then in charge of the home office—a remarkable letter (given in full in the *Historical Records of New South Wales*) in which he claimed a 'thorough knowledge of all kinds of land' and an ability for 'bringing indifferent lands to perfection,' and proposed to reorganize agriculture in New South Wales and 'render it a great deal more productive.' As a result of this offer he was released from Newgate, enlisted in the New South Wales Corps, sent back to the colony and on 5 September 1795 (in the last few days of Paterson's lieutenant-governorship) granted 25 acres of land 'in the district of Petersham Hill.' But of his efforts to reorganize Australian agriculture there is no trace left.

W.J.

Buckley, WILLIAM (1780-1856), born at Marton near Macclesfield in Cheshire in 1780, after a short apprenticeship to bricklaying joined the Cheshire militia, and in 1799 passed thence as a volunteer (being 6ft. 6in. high and of a fine figure) into the 4th regiment of the regular army and served in the Netherlands under the Duke of York. Two years later, on 2 August 1802, he was convicted at the Sussex assizes of receiving stolen property and sentenced to transportation for life. The story sometimes told of him, which represents him as having been involved in a conspiracy to shoot the Duke of Kent at Gibraltar, was probably invented by his first biographer, John Morgan, and is incompatible with official documents that give the facts stated above. Buckley was transported to Australia in the *Calcutta*, which carried the expedition under David Collins (q.v.) intended to occupy Port Phillip. When Collins in November 1803 landed his party near Sorrento, he chose Buckley for one of his body-servants; and the stalwart young adventurer, promptly taking advantage of the greater freedom thus ensured to him, almost at once slipped away from the camp with three others and took refuge with the natives. His example was followed, and before Collins abandoned the settlement 21 convicts had attempted flight, though two-thirds of them either were captured or returned voluntarily. Among those who did not return, and were accordingly believed to have perished miserably, were Buckley and two of his companions.

Nearly 32 years later, on 12 July 1835, the party which John Batman (q.v.) had left in occupation at Indented Head was visited by a band of natives one among whom was of great stature and distinctly European in features, with a tattoo mark 'W.B.' on one arm. After much questioning he was persuaded to say 'bread' when a piece was offered him, and in a few days he remembered other English words and was gradually enabled to give some account of himself. In later years a story, purporting to come from his own lips, of his adventures during the missing 32 years was published in Tasmania, but its authenticity is doubtful. It is probable, however, that on leaving Collins's camp he made north along the bay shores as quickly as possible in order to escape pursuit, but dared not go too far from salt water (hoping, it may be, to be picked up later on by a sealer or stray merchant-vessel) and so worked down the western shores into the Geelong district and (according to his own account) even into the Otway ranges. For over 30 years, it is certain, he had lived with the Geelong blacks, ranging northwards as far as the Yarra but usually camping near the You Yangs. What happened to his companions was never ascertained.

On 28 August he received a formal pardon, and was for a time employed by the Port Phillip Association as a go-between with the natives. When Lonsdale reached Port Phillip as superintendent at the end of September 1836, he—being a captain in the 4th regiment—was naturally interested in an old soldier of his own regiment, and on 11 October at Bourke's suggestion made him constable and interpreter to the aborigines. Lonsdale for a time placed great reliance on him, but Buckley soon proved to him, as he had already done to the association, that he was unintelligent, untrustworthy, and quite incapable of rendering any useful service in connection with the natives. Bourke recommended him for a pension, but the colonial office would not consider it. On 28 December 1837 he left his employment and went to Tasmania, where the government gave him small billets—assistant storekeeper at the immigrants' home, gatekeeper at the female penitentiary—and in 1852 retired him on a pension of £12 a year, which the Victorian government when appealed to made up to £1 a week. It was at this time (before the Victorians had come to his aid) that he collaborated to some extent in the *Life and Adventures*. Early in 1856 he was thrown out of a cart, and died of his injuries on 2 February.

The Life and Adventures of William Buckley, by John Morgan, was published at Hobart in 1852. James Bonwick in 1856 published a monograph on Buckley, and many authors have used his career as a peg for an account of the Port Phillip aborigines.

Budgerigar. See PARROTS.

Buffalo, the vernacular name of *Bubalus buffelus*, a species of cattle native to India, which has spread in a semi-domesticated form to Italy on the one side and the Malay Archipelago on the other. In 1825 Maurice Barlow, then commandant at Melville Island, imported three buffaloes to that station from Timor; as they throve, and the cattle sent up from Sydney did not, another consignment of 15 was imported in December 1827, and 16 more in August 1828, out of which eight were sent to Raffles Bay. In February 1829, however, Collett Barker reported against further importations: the buffaloes, he said, were too poor to kill on arrival and too wild

to retain in captivity when once ashore. When, however, the Port Essington settlement was garrisoned in 1838, buffaloes were again imported from Timor, so that, when in 1849 that settlement also was abandoned and northern Australia left for a time to itself, there were several buffalo herds in existence. Those on the mainland, following their instinctive desire for water, left the Coburg Peninsula for the swamps of the lower Alligator valley and rapidly increased in numbers. In 1857 the beginnings of a new herd were made by accident. The barque *Florence Street*, chartered to bring buffaloes to Sydney to supply an exceptional demand for meat on the diggings, loaded up at various ports of the Malay Peninsula and Burma, and on her return voyage was caught in a typhoon and driven ashore in Cambridge Gulf; most of the beasts she carried were drowned, but some escaped to shore and established themselves in the water-meadows of the lower Ord. In 1885 Thomas Cahill discovered great herds in the Alligator valley, and proceeded, with two or three partners, to kill them off for their hides at the rate of 1500 to 2000 a month; although it was estimated that the herds numbered at least 60,000, this rapidity of destruction soon reduced them to scarcity. Another hunter rented Melville Island, with about 6000 buffalo, and exported hides at the rate of 2000 a year. In 1912 it was still possible to report officially that buffalo were numerous, but by 1923 it could be said only that they 'formerly existed in large herds.'

Bugs. See HEMIPTERA.

Building and Ornamental Stones.

The existence of good building stone in Australia was discovered by the first settlers, and from an early date the sandstone of Sydney, which is considered one of the best building materials on the continent, has been freely used; later, one or two local granites, in which Australia is particularly rich, were introduced; more recently still local marbles, the supply of which is practically inexhaustible, have been much favoured by architects. To-day local stone is a prominent feature in all the cities of the Commonwealth, especially in Sydney. The first specimens exhibited abroad were sent to the exhibition of 1851; the finest collection was shown at the Franco-British exhibition held in London in 1908, and was awarded the Grand Prix, the jurors stating that 'the exhibits of marbles were especially noteworthy, and served to convey to British and Continental architects an adequate notion of the richness of New South Wales in these splendid materials, some of which were admitted by competent judges to surpass any European marbles found in commercial quantities.'

Granites are fairly well distributed throughout coastal Australia, in bosses and huge outcrops as well as in veins or dykes; they are not known to exist on the plains of the interior. In colour they range from dark red to pale pink, and from various shades of grey to evergreen. In texture they may be described as 'very coarse,' 'medium,' and 'fine.' In a crushing-strain on a 3-inch cube with a 100-ton testing-machine the results varied from 55 tons to 70 tons. Very few flaws occur, so that during preparation for use the granites require no 'filling in' or other methods of cobbling to produce an even and regular surface. They have not been exposed long enough for their durability to be tested. *Red granites* have scarcely been exploited commercially. The best in use at present, which comes from Gabo Island, is a particularly good fine-grained decorative granite, the constituents being mixed in about equal proportions, and so producing a fairly uniform texture. The colour is often a deep red. This and the Tarana granite (of similar texture) are the only two on the market in New South Wales, but in South Australia 'Murray Bridge' red is also used. In New South Wales several rich red coarse-grained granites, the felspar predominating, have recently been found at Mudgee, Michelago, and Tarana; red granite also occurs in the State at Albury, Burrinjuck, Braidwood, Cowra, Bungendore, Carrick, Cooma, Grenfell, Inverell, Jerangle, Jindabyne, Cox's River, Lithgow, Maffra, Mulloon Creek, Murrumbateman, Rylstone, Tarago, Trial Bay, and Wombeyan; in Victoria at Beechworth, Inglewood, and Woolamai; in Queensland, at Stanthorpe and Townsville; in South Australia at Midgee near Charleston, and Wudinna; in Tasmania at Heemskirk. *Grey granites* occur more extensively than the red and vary similarly in texture, structure, and shade. They are all first-class building stones —the dark grey of Uralla being the finest and most easily worked—and are used extensively in the State capitals. In New South Wales they are found at Adelong, Albury, Arnprior, Bathurst, Braidwood, Breadalbane, Bredbo, Bungendore, Burrowa, Collingwood near Gunning, Cooma, Cowra, Goulburn, Gundagai (this is a particularly beautiful granite but too hard to be much worked), Gunning, Harden, Inverell, Jerangle, Lake Bathurst, Montague Island, Moruya, Oberon, Tenterfield, Trial Bay, Tumut, Uralla, Yass, and Young; in Victoria at Beechworth, Harcourt, Harrow, Tallangatta, and Trawool; in Queensland, at Greymare west of Warwick, Enoggera and Mount Crosby west of Brisbane, and Cooktown; in South Australia at Minnipa, Moody, and West Island; in Western Australia at Meckering; in Tasmania at Gladstone. Other granites occur which can hardly be classified as grey or red; the colour is variegated, green predominating, due to the abundance of green felspar intermixed with pink. Such a stone occurs at Albury, Braidwood, and Bungendore in New South Wales.

Enormous masses of *gneiss* are scattered throughout the Commonwealth, notably in South Australia and on the west coast of Tasmania; but the possibilities of this rock as a building-stone have not yet been tested on a large scale though the court-house at Goulburn, the post-office at Cooma and churches in several inland towns are built of it.

Trachyte, so-called, is a favourite stone with Sydney architects. Petrologically it is not regarded as a trachyte, but rather as a syenite (Bostonite). Commercially it is known as Bowral trachyte, and is obtained in the locality from which it derives its name. It is of unique colour—a dark olive-green, or perhaps dark grey. Occasionally it is streaked with narrow veins of sanidine (glassy orthaclase), hornblende and aegirine crystals. It takes a fine polish, and some of the finest architectural structures in Sydney are built of it. At Orange in New South Wales there are large flows of true trachyte, which is of great repute amongst local builders: it is very hard and durable, polishes to a soft grey or buff base colour and makes a good flagging-stone for pavements.

Porphyry occurs in almost any portion of the southern tableland of New South Wales, in con-

junction with Silurian and Devonian rocks. It takes a beautiful olive-green polish much resembling that of serpentine, but its hardness will always give it a constructional superiority over the softer material. Churches have been constructed of it in districts where it occurs. A large outcrop of felspar porphyry is found in the Gawler Ranges of South Australia.

Diorite, in spite of its frequent good colour, is not favoured by architects owing to its hardness, which adds to builders' costs. Near Goulburn in New South Wales a fine-grained, dark coloured diorite is extensively developed, and the rock, which takes a good polish, has been largely used in the construction of local buildings. Other places in New South Wales from which this stone has been recorded are Bumbaldry, Jerangle, Tarago, Tumut, and Wee Jasper; in Victoria, Stringer's Creek and Walhalla.

Basalt is fairly common throughout the eastern States (as a volcanic outcrop in many places) showing in its distribution varying textures, from very fine to coarse and vesicular; all varieties have been used more or less in architecture in Victoria, and occasionally in New South Wales and Queensland.

Dolerite. There appears to be no record of the utilization of this stone as a building material proper (so to speak); but it has been tested in the form of steps, and found durable and satisfactory, as it neither wears smooth nor takes a high polish.

Marbles are probably the most extensively distributed and valuable of all Australian building material; it is doubtful if any other country is so rich not only in amount but in variety of material. The first-known deposit was discovered by surveyor Davidson in 1842 on Burangylong (Grove) Creek, a tributary of the Abercrombie River on the western slopes of the main range in New South Wales. The creek, Davidson wrote to Sir Thomas Mitchell (q.v.), runs under a tunnel, and in the tunnel were 'masses of the most beautiful white marble.' This tunnel is better known as the biggest of the Abercrombie caves (see LIMESTONE CAVES).

As yet only the surface deposits have been worked. The more populous States have, of course, opened out most quarries. Next to New South Wales, South Australia has given most attention to her marbles, and has worked some quarries for a long period, but lack of population has militated against their greater development. The occurrence of marbles in Victoria has long since been ascertained, but known deposits occur in remote localities, and hence are costly both to produce and to transport. Queensland is rich in marbles, still unexploited. Throughout Australia the industry is only in its infancy, but specimens are exhibited at the various State museums. The marbles have very few flaws and require no 'filling in.' They are of the usual scale of hardness, but are far more compact than imported marbles, and under a compression test on a 100-ton machine endured a higher crushing strain than granite. Their durability has not yet been tested. Marble deposits are known at the following places:—

New South Wales:—Abercrombie, pale, almost white; Adelong, white and green; Attunga, brecciated, coarse, on red ground (the most decorative of the marbles—when polished it shows exceptionally big fragments, and so produces figures suitable for majestic columns in large buildings); Bibbenluke, black and white; Binalong, sage-green; Bingara, brecciated; Borenore, a breccia of various colours, red and blue predominating; Brungle Creek, white; Buckeroo, many-coloured; Bumbaldry, mostly red; Bungendore, dark grey; Bungonia, buff-coloured; Burrowa, red; Caleula, whitish ground, with red, green and yellow bands—a beautiful stone, extensively used in Sydney for internal decoration; Caloola, white; Carrol, variegated; Coolalie, white, with reddish or yellowish tinge; Cooma, white; Cow Flat, whitish; Cowra, dark; Cudal, bluish black; Fernbrook, many-coloured; George's Plains, white; Gilmore (near Tumut), fine statuary marble equal in quality to Carrara, also a yellow-and-black-banded variety; Goulburn (Shea's Creek), red; Gundagai, little known; Havilah, white; Jeir, chocolate; Jenolan, unworked; Kempsey, of warm chocolate colour, with small white crinoids; Limekilns (near Bathurst), many-coloured; Marulan (the first marble worked in Australia), variously marked; Michelago, variegated; Molong, many-coloured; Moonbi, extensive but undeveloped; Mudgee, many-coloured; Nemingha (crinoidal) rich red ground, ornamental; Orange (Douglas), black with white streaks; Parkes, variegated—and white statuary marble at Ashburnham; Portland, reddish coloured; Queanbeyan, laminated, with a great variety of colours; Rockley, black and white; Rylstone (a locality rich in marbles), (*a*) black and white, (*b*) ivory ground with yellow veins, and rich, (*c*) a yellow marble of great beauty which, like the ivory of the same district, is unique among Australian marbles, (*d*) satin grey, (*e*) rose-coloured; Springhill, black with well-marked fossils; Tarago, black with yellow veins; Taree, grey, oolitic; Tarrabandra (near Tumut), white; Tumut, variegated; Warialda, white ground, black stripes—also a red, very ornamental; Windellama, black, comparable almost with the black marble of Belgium; Yass, black—also a fossiliferous variety. In New South Wales no distinctly blue marble is yet known, but the Marulan marble has sometimes blue markings.

Victoria:—Buchan, two-coloured marble, black and grey or drab, also one with white streaks (the black Buchan marble is in the same class with the marble of Windellama); Galena Point (near Geelong), a stratified limestone, coloured or striped—'has a handsome appearance when polished,' Chapman states; Limestone Creek, (*a*) with red and pink markings on a white ground, (*b*) pale grey, (*c*) slate-coloured; Mansfield, crinoidal, with white streaks and dark markings; Martin Creek, black; Moorabool, with a yellowish tinge; Mount Tambo, bluish, fine-grained; Orbost, fawn ground with pink and white streaks; Thomson River and Toongabbie, both black, with white crinoids; Waratah Bay, black with white streaks; Waurn Ponds, dark yellowish or buff.

South Australia:—Angaston, (*a*) white with cream tints, (*b*) pink; Kapunda (the main source of supply for South Australia), (*a*) fine grey, with dark and lighter patches, (*b*) pale fawn-coloured, (*c*) grevish ground, with banks and streaks of black; Macclesfield, several varieties, the principal being (*a*) cream, (*b*) grey, (*c*) dark grey, (*d*) pink, (*e*) red.

Queensland:—Broken River, west of Townsville, fine white marbles, taking a good polish; Calliope, near Port Curtis, white (could be used for statuary), also fine-grained pink, blue and red; Chillagoe, fine white; Marmor, 26 miles south of Rockhampton, dark blue with large encrinites; Northumberland Islands, white, pink and blue; Rosedale, north of Bundaberg, blue and white; Ulam, south of Rockhampton, coarse

white. Marbles are also reported from Herberton, Mount Roundback near Bowen, and the area between Inglewood and Texas on the New South Wales border.

Western Australia has not yet been exploited for marbles.

Australia has extensive areas of *slate* country. Good building slates have long been known, and several varieties quarried; they are undoubtedly good roofing slates, comparable with those at present imported.

In *serpentine* Australia is rich. It has not received much attention except in New South Wales, where it occurs in the Gundagai, Macleay River, Port Macquarie, Tarrabandra, and Tumut districts. In Queensland it has been reported from Canoona, Kandanga south and Kilkivan west of Gympie, and Cawarral north of Rockhampton.

With *sandstone* of building quality Australia is very fairly provided. The extensive 'freestone' deposit on which Sydney is built affords an excellent building stone. Victoria has so far not yielded a good freestone. The deposits in Tasmania and Queensland have been used in public buildings, and Western Australia has a good sandstone at Donnybrook. Ravensfield sandstone, quarried near Maitland in New South Wales is of a warm sepia-brown colour, and is finer in texture than the Hawkesbury variety. The sandstones of Australia vary in grain, texture, and colour and so lend themselves to widely different schemes of architectural beauty. Their durability has been well proved—e.g. the Macquarie obelisk at Sydney shows no signs of decay after an exposure to the weather of more than 100 years.

See the *Official Year Book of the Commonwealth*, No. 9, pp. 446-466; No. 12, pp. 89-95.

R.T.B.

Bulbine, a genus of the family Liliaceae, consisting of perennial herbs (very numerous in Africa) with long awl-shaped leaves and a more or less tuberous root-stalk. The two species indigenous to Australia, *B. bulbosa* (Wild Onion) and *B. semibarbata*, have yellow flowers scattered singly along a slender flower-stem; capsule nearly globular, with a few black seeds. The wild onion, which is endemic in Australia, is reputed to be poisonous to stock.

Bull, John Wrathall (1804-1886), born at St. Paul's Cray in Kent on 23 June 1804, at an early age turned his attention to farming and became a dairy farmer in Cheshire. In 1838 he migrated to South Australia to deal in stock, buying from the overlanders to re-sell to new arrivals; but the financial crisis of 1839 drove him to abandon this business and settle near Mount Barker as a stock-owner, with agriculture as a side line. The crisis of 1842-3 (which affected all the Australian settlements) again brought him near ruin, and he was forced to concentrate on agriculture: his attention was thus called to the very primitive methods employed, requiring a great number of field hands, who at the time were unobtainable except at exorbitant wages. He devised the plan of 'thrashing a standing crop'—i.e. taking the grain from the ears as they stood and leaving the straw untouched in the field. In September 1843 he exhibited a model constructed on this principle, but it found no favour except with John Ridley (q.v.), who immediately constructed a reaping machine that was successfully used during the ensuing harvest. A good deal of heat has since been developed over the question whether Bull or Ridley should be credited with the invention of the 'stripper,' but Bull himself never complained: his own account is that he had placed his model at the service of the public, he himself and several others afterwards constructed machines embodying the stripping principle, and of them all Ridley's, which was the first, proved also the most suitable. In 1882 parliament voted him £250 in recognition of his share in the improvement.

In 1852 Bull went off to the Victorian goldfields and had moderate success, but returned in 1853. He then became manager of the Gillies estate at Glen Osmond, planted a vineyard there, and established a depot in Adelaide for the sale of his own and other colonial wines. Some years later he began to write a history of the colony, and circulated many chapters of it privately: this resulted in the publication in 1875 of *Early Experiences of Life in South Australia*, an unsystematic but often illuminating account of the first 50 years of the colony's existence from a non-political point of view. He died on 21 September 1886.

Bullhead. See Port Jackson Shark.

Bull Oak. See Casuarinaceae.

Bullrout, a common estuarine fish (*Notesthes robusta*) of the northern parts of New South Wales and Queensland, which ranges upstream to fresh water. It is armed with large movable spines on each side of the snout and others on various parts of the head, and its dorsal and anal fins are each provided with a row of stout spines; some of them have definite venom-glands at their bases, and grooves on each side to convey the poison into any wound they may inflict. The bullrout is fond of lying quietly among stones and weeds in rivers; if trodden upon by an incautious wader, it inflicts injuries that cause intense pain and inflammation. It is marbled with brown and black, and reaches a length of 12 inches. Notwithstanding the venom-glands, the flesh of the bullrout is good eating. A.R.McC.

Bulrush, the popular name of *T. angustifolia*, the only species indigenous to Australia of the genus *Typha* (family Typhaceae), which consists of reed-like marsh or aquatic herbs with a creeping tuberous subterranean stem from which the leaves and flower-stems arise. The Australian species is possibly identical with the common European form (*T. latifolia*), which is widely distributed. The flowers are unisexual; petals and sepals represented in the males by spoon-shaped scales, and in the females by a ring of hairs; the whole, when matured, packed in a soft, brown, dense, cylindrical, cushion-like spike at the top of the flower stem 3-6 inches long and one inch in diameter, the males above, usually separated from the females by a short bare interval; flowering stems erect, 6-10 feet high; the flat, narrow leaves slightly longer. The Lachlan River aboriginals call the plant 'balyan' and (according to Sir T. L. Mitchell) use the rhizomes to make a sort of flour; others masticate the fibrous part of the root-stock and make it into a coarse twine. On the Murray River the soft woolly flower spikes are collected and sold for stuffing pillows. The root-stock, which abounds in starch, is astringent and is used in eastern countries in cases of dysentery.

Bunyip, an apparently fabulous animal supposed to haunt swamps and shallow lakes in Australia and Tasmania. While there is no evidence for the existence, now or in any age, of a large

marsupial otter, such a creature is not unthinkable. But, even if it did at one time exist, and was the origin of the 'bunyip' legend, its qualities and features have been so confused with those of crocodiles in Queensland and seals on the southern coast that the resulting monster—in which many aboriginal tribes firmly believed—can only be described as fabulous. Latrobe during his administration of the Port Phillip district was assured by the neighbouring tribes that there were two kinds of bunyip, and on 23 September 1847 sent to a correspondent in Tasmania sketches of the 'southern' type copied from aboriginal drawings: these have unfortunately disappeared. About the same time a skull found in 1846 on the banks of the Murrumbidgee was submitted to W. S. Macleay as that of a bunyip; but he pronounced it that of a much deformed colt, and Professor Owen afterwards decided that it was a calf's. One of the few specimens described by alleged eyewitnesses—that said to have been seen in a lagoon north of Narrandera, early in 1872—was described as 'about half as long again as an ordinary retriever dog, the hair all over its body jet black and shining, its coat very long;' this would accord with the hypothesis of a marsupial otter. The second appearance, at Dalby in Queensland, dates from 1873: it had 'a head like a seal, and a tail consisting of two fins, a larger and a smaller one.' The Great Lake in Tasmania has several bunyips to its credit: one bumped a boat in 1863, and in 1870 Francis McPartland saw three or four together; it is noteworthy that seven observers in this locality, covering about ten years, agree in describing the animal as like a large sheepdog about the head and from three to five feet long. The aboriginal monster (also called Bunyup, Kyanprati, and Tunatpan) was a far more fearsome beast: it was as big as a bullock, with an emu's head and neck, a horse's mane and tail, and seal's flippers, which laid turtle's eggs in a platypus's nest, and ate blackfellows when it was tired of a crayfish diet. This description came from a Port Phillip tribe. For the boom which was (and in some localities still is) believed to be its call bitterns are probably responsible.

Burdekin Vine. See VITIS.

Burke, ROBERT O'HARA (1820-1861), born at St. Clerans in county Galway and educated in Belgium, entered the Austrian army in 1840 and attained the rank of captain, but in 1848 returned to Ireland and joined the constabulary. In 1853 he migrated to Tasmania, but shortly afterwards crossed to Victoria, where he was appointed inspector of police. Obtaining leave in 1854 to visit England, he applied for a commission in the army with a view to service in the Crimea; but the war was over before his arrangements were completed, and he had to return to Victoria and resume his duties as police inspector. In 1859 he was chosen by an 'Exploration Fund Committee' to lead an expedition across the continent from Melbourne to the Gulf of Carpentaria. The expedition (for details of which see EXPLORATION BY LAND) was equipped from public and private funds under the direction of the Royal Society of Victoria; but, largely owing to Burke's impatient temperament and complete ignorance of bushcraft, it failed hopelessly, and Burke and his second in command, W. J. Wills, died of exhaustion on Cooper's Creek towards the end of June 1861.

Burns, SIR JAMES (1846-1923), born at Polmont near Edinburgh on 10 February 1846 and educated at the Edinburgh high school, migrated with an elder brother to Queensland in 1862 and, after some years of pastoral experience was just about to join his brother in the management of a store near Brisbane when in 1867 gold was discovered at Gympie. Young Burns was the first man from Brisbane to reach the field, and in a few months was controlling stores at three mining centres, besides acquiring an interest in several mines. In 1870 he revisited Scotland, and on his return to Queensland in 1873 found that the Charters Towers goldfield, discovered the year before, was rapidly making Townsville an important port. He settled there, developed a business both as storekeeper and as shipping agent, and took into partnership Robert Philp (q.v.), whom he left in charge in 1877 when he decided to make Sydney his headquarters. In 1883 he founded the firm of Burns, Philp & Co., by formally amalgamating his own businesses at Sydney, Thursday Island, and Normanton with those carried on in Philp's name at Townsville, Charters Towers and Cairns. This firm both by its shipping enterprises and by its ventures in storekeeping, timbergetting and pastoral work pioneered the development of great areas in northern Queensland, and gradually extended its operations to New Guinea and the islands of the western Pacific; its fight with the German government over an attempt to exclude its trading vessels from the Marshall Islands in 1904-8 became a matter of Imperial concern, and established a precedent in international law.

But Burns was not merely a business man. In 1888 he enlisted in the New South Wales lancer regiment, in 1891 was made captain of the Parramatta troop, and in 1897 became colonel of the regiment. In 1904 he became brigadier-colonel commanding the 1st brigade of Australian Light Horse, but retired in 1907, in which year also he was nominated to the legislative council. For 19 years he was president of the New South Wales Highland Society, and for 12 a trustee of the Australian museum. During his later years his chief interest was the Burnside homes for orphans, built on his own land at Gowan Brae near Parramatta and largely endowed by him. He died at Gowan Brae on 22 August 1923. (K.C.M.G., 1917.)

Burrawang, the popular name of *Macrozamia spiralis*, the best-known and most abundant species of the genus *Macrozamia* (for which see CYCADACEAE). The name is said to have been given because the tree is common round Burrawang (near Moss Vale in New South Wales); but its original form is 'burwan,' and the form 'burrawong' is used for a Queensland species. *M. spiralis* extends coastally from Victoria to Queensland. In some districts the stem reaches a height of 6-7 feet, but it is usually 6-18 inches high. The upper part is covered with a fine brownish wool (*pulu*) used for stuffing couches, mattresses, and other upholstery. A large percentage of power-alcohol has been obtained from the trunk. The leaves cause rickets in cattle browsing upon them; the matter is still under investigation, but no poisonous substance has been detected, and the opinion is generally held that the disease arises from malnutrition caused by eating a bulk of indigestible fibrous matter. The palm-like

leaves, when dried and treated with a preparation which preserves their colour, are used for decorative purposes. Before the war the preparation of these and other ornamental leaves, including the Giant Maidenhair (*Adiantum formosum*), had become a minor industry in the coastal districts. Since the war several by-products have been discovered, including a dye said to have the qualities of cochineal, and fibre from which a paper-pulp useful for belting or packing can be manufactured; the 'bulbs' also contain 15 per cent of starch and 30 per cent of pollard, the latter having been found useful as cattle-fodder in time of drought.

Burrs. See NOXIOUS PLANTS.

Burt, SIR ARCHIBALD PAULL (1810-1879), was born at Richmond in England in 1810, and educated at a private school; he studied law at Oxford, and in 1845 was called to the bar. From 1849 to 1860 he was attorney-general of St. Kitts (in the West Indies), a member of the executive and legislative councils of that island, and for some time acting chief justice. In 1860 he was transferred to Western Australia as civil commissioner and chairman of quarter sessions and next year became chief justice. He died on 21 December 1879. (Kt. Bach., 1873.)

Burton, SIR WILLIAM WESTBROOKE (1784-1888), born at Daventry in England on 31 January 1794 and educated locally, entered the navy in 1807, saw service in the Mediterranean, on the East Indies station, and off the coast of North America; he was wounded during the blockade of Toulon in 1811, and took part in the fight off New Orleans in 1814. The subsequent peace seemed unlikely to provide excitement or promotion; so he left the navy to study law (his father's profession), and in 1824 was called to the bar at the Inner Temple. In 1826-7 he was recorder of Daventry, and in 1828—having devoted some time to the study of Roman-Dutch law—was made a judge of the supreme court of the Cape colony. Transferred in 1832 to New South Wales, he was sworn in as judge of the supreme court there on 22 December. His term on the bench was notable for two important decisions—the one (provoked by his claim to be senior to Judge Dowling) that the supreme court of the colony was a body distinct from any other British court, and that previous appointments to other benches did not carry with them seniority in New South Wales; the other, the fruit of his own persistence, enforcing a neglected rule that barristers only should be heard in court, whereas solicitors had hitherto illegally enjoyed the right of audience. In 1844 he was transferred to the supreme court of Madras, thus missing by a few weeks his excellent chance of becoming chief justice of New South Wales at the death of Sir J. Dowling. Soon after his arrival in India, becoming chairman of the Madras Indian Emigration Society, he initiated a movement for sending Eurasians to Australia as colonists; Henry Parkes, at that time editor of the *Empire* and confronted with a strike among his compositors, arranged with Burton for the supply of 25 to 30 Eurasian compositors; but the experiment was not repeated. In 1857 Burton retired on a pension and returned as a private citizen to Sydney, was immediately nominated a member of the legislative council, and on 9 February 1858 became its president. In 1861, however, the council having rejected John Robertson's land bill, it became known that 20 new members were to be nominated to that body for the purpose of carrying it. When the 20 were assembled outside the chamber to be summoned, Burton announced from the chair that he heard that certain persons were waiting to be sworn in, but had had no official intimation of their nomination; regarding this as an insult to the house and the chair, he intended to resign, and would at once leave the chair—which he did, followed by 19 other members and making it impossible to form a quorum. The result of this action is narrated under WENTWORTH, W. C. It made Burton's renomination to the council (whose term expired three days later) impossible; he therefore left the colony, retired to private life in England, and died on 9 August 1888. Both at the Cape and in New South Wales he is remembered as a useful and upright judge, whose presence on the bench ensured public confidence and respect. He was the author of two publications, one (1842) on the insolvency laws of the colony, the other (1840)—which provoked an answer from Dr. Ullathorne—*The State of Religion and Education in New South Wales.* (Kt. Bach., 1844.)

Busby, JAMES (1800-1871), born in Scotland on 7 February 1800, was the second son of John Busby, for whom see below. In 1822 he visited the vineyards of the Bordeaux district in France, and on arrival in New South Wales with his father in 1824 compiled a *Treatise on the Culture of the Vine* which was published by George Howe, the government printer, in 1825. Brisbane, to whom it was dedicated, at once set the author to experimenting with the agricultural establishments for convicts that had been recommended by J. T. Bigge, and in December made him manager of the estate whose revenue supported the boys' orphan school, Busby agreeing to teach the boys vine-culture in return for one-third of the farm produce. The trustees of the clergy and school lands corporation, when in 1826 they took over the estate, dismissed Busby and closed down the farm, thereby initiating a long quarrel about his claim to his share of the produce, which in the end he recovered from the colonial government. Darling promptly made him collector of internal revenue—a new office, which he had to organize from the start—and employed him on the land board and on many boards of enquiry; when in 1829 he was superseded as collector by a nominee from England, he devoted himself to land board work, but in January 1831 refused Darling's offer of the secretaryship to the board, and proceeded to England in February to press a claim for compensation. In 1830 he had published a second book on vine-culture, the *Manual of Plain Directions*; after visiting London he went off to Spain on 6 September, traversed the vine-growing districts from Cadiz to Malaga, and those of France from the Pyrenees to Champagne, and obtained at Montpelier 437 vine-cuttings and at Paris 133 more (570 varieties in all). These he presented through the colonial office to the Sydney botanic garden, where in January 1833 362 were alive. In March 1832 he handed over 540 cuttings from Spanish vineyards, including raisin, dessert, and wine grapes, and a collection of seeds and fruits of the date, pumpkin, tomato, cucumber, onion, melon, and sweet pepper. This assiduity, combined with the intelligence he had shown as a witness before a parliamentary committee on secondary punishments, led Goderich—then col-

onial secretary—to appoint him resident in New Zealand. In June he left England for his new post, taking with him a letter addressed by Goderich to 'the Chiefs of New Zealand' and an order on Bourke for the supply of presents 'of inconsiderable value' for those chiefs. A warship conveyed him to New Zealand, but once there he was left to the protection of moral influences only. On 16 May 1833 he reached the Bay of Islands and inaugurated an administration sufficiently described under NEW ZEALAND.

In 1839 the New South Wales authorities urged on the colonial office that Busby's salary should no longer be a charge on the colony, since it derived little advantage from his work in New Zealand. It had, however, been already decided in London to abolish his position as resident, and on 29 January 1840 William Hobson (q.v.) reached the Bay of Islands from England with a commission appointing him lieutenant-governor of New Zealand. Busby gave Hobson loyal and unremitting support, revising for him the draft treaty of Waitangi (which was discussed and promulgated at Busby's house) and obtaining the signatures of important chiefs. With the intention of settling permanently in the island he had bought from the Maoris in strict accordance with their customs a block of 40,000 acres of grazing land at Whangarei and another of 10,000 acres of timber land near Auckland, and had erected a sawmill on the second block. Visiting Sydney to buy cattle, he was astonished to find that Gipps —disgusted by Wentworth's attempt to assert possession of 20 million acres in South Island on very flimsy pretexts—was pushing through the legislative council a bill that cancelled all existing titles of any sort to New Zealand land. Despite Busby's endeavours—on 30 June 1840 he addressed the council at great length on the subject—the bill was passed, though afterwards it was disallowed by the colonial office because, before it could be ratified, New Zealand had been made a separate colony. Busby returned to the Bay, could get no satisfaction from Hobson, went off to England to press his claims, and came back in 1846 unsatisfied to settle down on what land was left to him and maintain close relations with the missionaries. From 1850 to 1860 he poured forth a stream of pamphlets on local problems, especially (in 1857-60) on the difficulty of establishing truly responsible government in a discordant and half-Maori community. He had never renounced his claim to the land taken from him, and in 1864 went back to England to make further attempts to gain, if not the land, at least compensation for the loss of it. Eventually he was awarded £36,800 by arbitrators appointed in New Zealand. The government, not having so much spare cash, paid him with scrip that would be accepted, it said, at its face value in payment for any crown lands on sale in the province of Auckland—whereupon, according to Busby's story, the superintendent of lands promptly withdrew from sale every block of land in the province that was of any value. While on a visit to England undertaken in the hope of removing this final obstacle, Busby died in July 1871.

Busby, JOHN (1765-1857), born at Alnwick in Northumberland in 1765, was trained by his father, a coalmaster, to his own business, and was at the age of 19 manager of a coalmine. Gradually developing special skill in mine-locating and surveying, he adopted the profession of mineral surveyor and civil engineer, worked for three years on the Downshire estates in Ireland, and settled in Scotland, where he surveyed several counties for minerals and water and was employed on many important public works, including the water-supply of the fort at Leith. In some way (probably through the Downshire interest) he came under the notice of J. T. Bigge, who recommended him to the colonial office as a fit person to supervise coal-mining at Newcastle and devise a satisfactory water-supply for Sydney. He was accordingly engaged in March 1823 for a three-year term at £200 a year, with the right of private practice 'outside 200 days in each year;' if he was found useful, he might be granted a block of land and retained for two years more. If he chose to devote his whole time to public business, a house would be provided for him. So valuable were his services expected to be that Brisbane was instructed, if Busby considered Tasmania outside his contract, to make special terms with him for an investigation of the island's mineral resources. Moreover, he received extra pay for any days worked over 200 a year, and on one occasion at least received in addition to his salary a large reward for re-floating a government vessel.

On his way out he stayed for a short time in Tasmania to investigate deposits of coal that had been reported from Coal River and Schouten Island: his opinion of the island coal was very favourable. He reached Sydney on 24 February 1824, was at once sent off to superintend mining operations at Newcastle and to construct a breakwater there, and then spent eight months in salving the government brig *Elizabeth Henrietta*, which had gone ashore on a New Zealand beach. But his most important work was the construction of Sydney's first regular water-supply. In 1825 the town depended on (*a*) private wells, (*b*) the tanks at the corner of Hunter- and Pitt-streets, (*c*) water brought in barrels from the Blackwattle swamp on the west and the Lachlan and Botany swamps on the south. Busby's first proposal was to pump water from the swamp at Waterloo to a reservoir in Hyde Park, driving the pump either by steam-engine, a water-wheel, or a treadmill propelled by convicts; he favoured the water-wheel. The colonial office characteristically found the treadmill proposal the only part of his scheme that it could thoroughly approve; Bathurst thought it an excellent idea to spread among possible criminals in England the news that transportation might involve consignment 'for years together to labor in the Tread Mill.' But in 1826 Oxley and Dumaresq concurred in a new suggestion of Busby's, that 'driving a Mine the whole way' would bring the water into Sydney at a level high enough to supply most of the town, and a small water-wheel at the town end would pump enough to supply the rest of it; and in September 1827 the work was begun. Darling valued Busby's work highly, and proposed to increase his salary to £500 a year with allowances, but the colonial office was restive about the cost of the settlement, and had been receiving from an aggrieved person named E. S. Hall (editor of the *Monitor*) charges of favouritism and extravagance against Darling, which included the statement that Busby and his sons were drawing about £1600 annually of government money. So Darling had to compromise on £500 a year without allowances, at the same time assuring the authorities in London

that it was quite impossible to dispense with Busby's services until the water-supply was in working order. Unfortunately the excavation by convicts of a tunnel 12,000 feet long and only five feet high was likely to be slow in completion if not continuously and thoroughly supervised; moreover, unexpected deviations became necessary to avoid quicksands in one locality and a bed of pipeclay in another. Busby, too, was growing old and infirm, so that Bourke insisted on the employment of his son William Busby as overseer, the salary being divided between father and son. Even so the tunnel (which is still in existence) was not completed until June 1837, although from 1830 onwards there had been a flow of water from it at the Hyde Park end, due to percolation through the strata in which it was bored. The Hyde Park reservoir was never constructed, the water being supplied to users through a standpipe. 'Busby's bore' sufficed for the needs of Sydney until 1849. When Busby retired on 30 June 1837, he received a gratuity of £1000 and a grant of 2000 acres on the Hunter between Branxton and Singleton; there he settled, and died on 10 May 1857.

His youngest son WILLIAM BUSBY (1813-1887), after completing his work on the tunnel, took up pastoral pursuits in the neighbourhood of Cassilis. In July 1867 he was nominated to the legislative council, and was a member until his death on 23 June 1887. An elder son, James Busby, is treated of separately above.

Bush Canary. See FLY-EATERS AND TREE-TITS.

Bushranging. Occasional cases of highway robbery occur to this day in Australia as in other countries. But in Australia the systematic practice of highway robbery, usually by small gangs, flourished exceptionally during two epochs, and was revived in unusual circumstances during a third. These three epochs must be carefully distinguished. In the first the robbers were convict escapees: in the second they were usually free men of an adventurous and lawless type, tempted by rich convoys of gold: the third epoch was concerned entirely with the doings of a single gang, the Kellys.

The name 'bushranger' with its variants 'bush-ranger' and 'Bush Ranger' seems first to have been used for the convict escapees about 1806; the *Sydney Gazette* of 4 May in that year uses it as a term needing no explanation. But the term then connoted their life in the bush rather than their habit of robbing, and was for many years used also of free and reputable men who spent most of their time in the bush. Thus as late as 1825 W. H. Hovell (q.v.) is described in the *Australian* as lacking 'all the qualities befitting a bushranger.' In Tasmania the escapees were at first called 'bolters.'

Convict bushrangers.—The first bushrangers were convicts who had escaped from assigned service, or from the road-gangs, and took to the bush to avoid recapture. Not finding in the bush much that they could live on, they were compelled to resort to robbery for mere sustenance: Bigge defines bushranging as 'absconding in the woods, and living upon plunder and the robbing of orchards.' Obviously the quality of the crime, apart from the actual absconding, depended on the character of the escapee, and Tasmania, being the gaol of twice-convicted and specially refractory convicts, produced the earliest and most violent bushrangers. Bligh in 1807 was 'much concerned' about the bushrangers who were annoying Governor Collins, and in 1809 reported that some of the crew of the *Porpoise* had joined a body of 60 bushrangers who were infesting the roads inland. Collins in 1807 offered an amnesty to those who would surrender, but early in 1808 had to prohibit the passage of boats across the Derwent because two notorious bushrangers (Lemon and Brown) were at large in the woods beyond. In March, however, Lemon having been killed and Brown captured, the embargo was taken off. Macquarie, who visited Tasmania in 1811-12, was deeply impressed with the need for destroying the gangs, but hoped to effect a good deal by means of another amnesty, which he proclaimed on 14 May 1814. A year's trial proved this policy useless, and Macquarie ordered Davey (his lieutenant-governor) to pursue the gangs with specially mustered parties and to offer rewards for their capture. Davey found even these measures ineffective, and of his own accord proclaimed the establishment of martial law in the island—an act for which Macquarie never forgave him.

Among the bushrangers mentioned by name in Macquarie's amnesty offer were Michael Howe and John Whitehead, the latter of whom had for some years been leader of a notorious gang. Both took advantage of the offer, and both within six months were back in the bush, collecting new accomplices and raiding the settlers on both sides of the Derwent. Before the end of 1815, however, Whitehead had disappeared—his fate is more fully discussed under HOWE, MICHAEL—and Howe became leader of the gang; he established almost naval discipline among his followers, raided the northern and southern settlements indiscriminately, and even corresponded as 'governor of the rangers,' with Sorell as 'governor of the town.' He was killed in 1818, most of the gang having been captured or killed before him, and the colony had a few years' quiet. But the establishment in January 1822 of a penal settlement at Macquarie Harbour on the west coast, where discipline was extremely severe and escape, though very difficult, not impossible, resulted in a revival of bushranging. Some prisoners escaped by land, suffering great hardships: the most notorious was Pierce the cannibal (1822-3). The principal gang was that of Matthew Brady, an educated man who had been transported to New South Wales for forgery and sent to Tasmania for insubordination. With twelve companions he stole a boat at Macquarie Harbour on 7 June 1824, landed nine days later near the mouth of the Derwent, and for nearly two years raided the settled districts from Launceston to Sorell. Brady forbade unnecessary violence, boasted that he never killed a man intentionally, severely punished members of the gang who were brutal to women, and was on the whole the least inhuman of Tasmanian bushrangers. In 1826 his gang was betrayed and broken up, and he himself captured by John Batman: by the end of April the last of the gang had been despatched, and the island thenceforth had comparative peace, though in 1832-3 a small gang (Britton's) infested the northern settlements, and in the early forties Martin Cash (q.v.) with two companions committed many robberies in central Tasmania.

The first act that could be called bushranging in Australia was a highway robbery reported by David Collins under the date June 1794: Collins considered it 'one step towards refinement' and 'at least a manly method of taking property.'

But serious bushranging on the mainland did not commence until 1822, when 34 bushrangers were hanged. In 1824 the raids of escapees occasioned the proclamation of martial law west of Mount York from 14 August to 11 December, and in the following year Brisbane was forced to take vigorous measures against them, both legislative and administrative. In 1826 a gang of seven had a fight with police near Bathurst, and in 1827-30 Donohoe and Underwood harried the Hawkesbury-Nepean settlers from Windsor to Bringelly. This was the 'bold Jack Donahoo' of the old bush song—which must not, however, be regarded as historical, since Donohoe was killed by a settler, not by the 'horse police.' Underwood is said to have been killed by his mates when they discovered he was keeping a diary of their robberies—an obvious prelude to turning King's evidence. In 1830 the evil had become so great that the legislative council passed a bushranging act almost unique in its severity. Among other things it provided that all suspected persons might be apprehended without a warrant: that anyone carrying arms might be arrested, and anyone suspected of having arms might be searched: that, if provided with general search-warrants, the police might enter or break into any house by day or by night, seize firearms found therein, and arrest the inmates. When convicted, robbers and housebreakers were to be condemned to death, and executed on the third day thereafter. The necessity of such an act was shown almost immediately by an outbreak near Bathurst in September 1830, which almost assumed the proportions of a convict rebellion. At first, it is said, nearly 80 convicts joined the gang, but after a week or two it had dwindled to 13 well-armed and desperate men, who beat off a body of settlers and two detachments of mounted police before they were captured by a company of the 39th regiment. The provisions of the act were rigorously enforced, and for some years bushranging died down, but revived again in 1839-42: it would appear that there was always a supply of potential criminals, but they needed a lead. This was given by John Lynch, the most callous of New South Wales bushrangers, who is believed to have committed at least nine murders before he was hanged in 1842 at the age of 29. Of a very different type was William Westwood (Jackey Jackey), who had been transported in 1837, when only 16 years old, took to the bush in the Goulburn district in 1840, and for some time robbed mail-coaches on the Bungendore road. Growing more daring, he frequented the main southern road, and even visited Sydney, but in 1841 was captured, sentenced to penal servitude for life, and after an attempt to escape from Cockatoo Island sent to Port Arthur. He escaped, but was caught in Hobart and sent to Norfolk Island: there in July 1846 he headed a riot, killed four policemen, and was hanged on 13 October, when only 26 years old. For many years later his memory was treasured by the 'old hands'—ex-convicts employed, after the abolition of transportation, on outback stations. Among the minor bushrangers of this period may be mentioned Comerford and Dignum, who in 1837 took to the bush from Yass and harried settlers in the neighbourhood of Melbourne: McKewin or McKeown, who levied blackmail on farmers near the Jenolan Caves (q.v.): Edward Davis, the 'Jewboy,' whose gang haunted the Hunter River valley in 1839-40, and were all hanged together in February 1841: and Scotchey and Witton, who in 1842-4 infested the Lachlan and Crookwell districts. Wilson and Green in 1839-40 raided the settlements east of Gawler in South Australia, and a gang headed by John Ellis ('Yankee Jack') had a short but exciting career in the Dandenong ranges in 1842. But by the forties settlement along the main roads was fairly continuous, a good deal of police protection was available, and the rewards of successful bushranging were not large enough to compensate for the ever increasing risks.

The Gold-robbers.—The discovery of gold—especially in New South Wales, where the diggings were widely scattered over distant and sparsely settled areas—completely altered the balance between gain and risk. In 1850 Sydney and a few small country towns—Bathurst, Goulburn, Maitland, and one or two others—were each the nucleus of a farming district, in which no settler was at a very great distance from his neighbours. The portable wealth of the country concentrated in these areas was easily defensible: the only line along which it could be easily attacked in transit was the line of road which connected Bathurst with Sydney by way of the Blue Mountain passes. By 1853 the whole face of the country was changed. Its wealth now came from out-of-the-way gullies or from crown lands never before opened up, and only connected with civilization by long, devious, and often dangerous tracks. In the western district of New South Wales alone, where there had been one critical point—Mount Victoria Pass—there were now half a dozen: from Ophir, from the Turon, from Louisa Creek, from Forbes and from Lambing Flat a few years later, the roads along which thousands of pounds worth of gold had to be sent climbed five-mile-long hills, wound through dense scrubs, and in one way or another exposed their traffic to unforeseen and hardly resistible attack. Settlement, too, had spread into the wilds, and small farmers maintained themselves with much struggling in half a hundred gullies among the foothills of the main range. It was among their sons, to a large extent, that the new school of bushrangers recruited itself. Convicts, or men who inherited the convict tradition, first revived the profession of highwayman: but soon there gathered round them the 'wild colonial boys' of the old song, young fellows with a taste for adventure and no great love of work, in whose training the moral element had been entirely left out. They saw miners making fortunes more by luck than by skill or foresight, and they took what seemed the easiest way of sharing in that lightly-won wealth. To stick up a mail-coach or a bank had a spice of adventure in it—and Australians were never wanting in pluck. And after all, the money they took (so they argued) was easily replaced; if to-day a Lambing Flat tradesman found himself the poorer by a few hundred pounds, it would take him no long time to fill his purse again from the earnings of his digger-clients.

This advent of the free-born bushranger produced new relations between the criminals and their fellow-countrymen. The banditti of the fifties and sixties had no need to skulk round outlying settlements, seeking refuge in caves or in lonely station-huts. Their refuge was ready to hand among their friends: the whole countryside was often in league with them; the coming of their natural enemies, the police, was known to them miles away by means of a

well-organized system of 'bush telegraphs.' Two things they stole—gold, from the townsfolk, because it was portable wealth: horses, from the squatters, to be the instruments of attack and of escape. In no way did they injure the small farmer class from which they sprang. They worked in gangs, well organized, carrying on several raids at once, or combining at a given moment to make a great stroke and then dispersing as rapidly to widely separated haunts. The police found themselves baffled and betrayed time after time by the very men whose interests they were trying to defend. For mounted constables represented the law, which is never really popular in half-settled countries: they represented property, which those who have none always look upon as fair game; they stood for the government—and the young Australian, more especially, has a preference for being 'agin the Guvnment.' On the other hand, the bushranger stood for pluck, and daring, and the bush ideal of romance: and so strong was his hold on the hearts of those who did not suffer directly at his hands that, whereas the townsfolk of Bathurst and its congeners were to a man for law and order, no small proportion of the townsfolk of Sydney was ever ready to join in petitions for the reprieving or release of some bandit hero. Such a one stood, as has just been said, for pluck and daring: yet it is part of the paradox of Australia that in no profession were true pluck and true daring so little needed. Nowhere else in the world could so much wealth have been won with so little real risk to life. Looming in the distance, no doubt, there was always the gallowstree, or the disabling and torturing rifleshot: but how easily these things could be avoided was proclaimed to everyone by the career of Frank Gardiner (q.v.), king and exemplar of all goldstealing bushrangers. Times without number he was either captured or surrounded by the police; but either his guards could be bribed, or his high official captor, in the moment of triumph, did something ineffably foolish, or—when at last he had been tracked to a quiet home in Queensland, and caught, and tried (though for one of his minor offences only), and consigned safely to perpetual gaol—mysterious influences stirred the heart of premier and governor, and Gardiner went free to America to live out cheerful days.

How mild were the manners with which a bandit could do profitable trade the curious will learn by studying the career of Ben Hall's gang. This was the great gang of the bush-ranging sixties; it raided even Bathurst, then the second town of the colony; it stuck up gold-escorts innumerable, and fought long fights with ardent police; it besieged a magistrate in his own homestead, and held him to ransom—thereby creating one of the two favourite Australian melodramas, that deals with the romance of Mrs. Keightley's ride to save her husband's life. From end to end of the western tablelands of New South Wales men may travel to-day through the places it made memorable—the 'notorious Wombat;' Bang Bang, so called long before three bushrangers and a couple of police constables exchanged forty shots at about as many yards and hit nothing between them but a hat and a bar-room; Canowindra (which is pronounced 'Canoundra'), the bush township that five of them held for three days, issuing written passes to people who wished to go out of town for dinner; most famous of all, the Weddin Mountain, haunt and refuge of all western outlaws, amid whose tangled gullies and baffling scrub the police time after time sought their prey in vain.

From first to last this gang included six men only, of whom the leader was but 25 years old when he took the lead, and the others ranged from that age down to 17. Of its exploits a very few have been mentioned above: its reputation may be guessed from a satirical paragraph that appeared in 1863 in *Bell's Life in Sydney* 'NARROW ESCAPE OF THE POLICE! ! !' it was headed. 'Last evening three bushrangers espied a large body of troopers, and immediately gave chase. The darkness of the evening favoured the escape of the troopers, and baffled the bushrangers. The appetites of captain McLerie and Sir F. Pottinger'—two police-superintendents—'continue in undiminished vigour.' Perhaps the most astonishing incident in the gang's career took place at the end of 1864. Two of the bushrangers had by this time been shot during attacks on stations, and one had surrendered himself by the advice of a Catholic priest: the three who were left had temporarily abandoned the western district, and were overhauling mail-coaches on the main road that connects Sydney with Melbourne. One day in November they set to work in grim earnest. They stationed themselves on a hill near Jugiong (a small hamlet on the upper Murrumbidgee), and soon collected about 60 prisoners. Everyone who came by was 'stuck up,' robbed, and forced to sit down in the bush out of sight of the road. This haul alone provided nearly £100: but the gang had bigger game in view. Presently a mounted policeman came along. He was ordered to surrender: when he refused, the three outlaws rode at him, firing. They fired nine shots, he fired six, but nobody was hurt: then he took his place with the 60, who had not stirred from their place of imprisonment. At last came the great prize, the overland mail-coach, with a constable as mail-guard and two more as escort (one of these was a sergeant and the other a sub-inspector, so they were picked men). Shots were exchanged: the sergeant was killed, the sub-inspector surrendered, the mail-guard ran away, and a police-magistrate, who was a passenger, helped to throw the mailbags out of the coach for ransacking. The 60 captives, guarded by one man—for two 'stuck up' the coach—remained passive, though some of them seem to have come out of the bush to watch the fight. When it was all over, Gilbert (the actual murderer) walked over to look at his victim's body. 'I'm sorry for him' he said, 'he was a brave fellow: I don't like to shoot a man, and he's the first man I ever shot.'

It is an incredible story, but true in every particular. Gilbert had been Gardiner's right-hand-man before he joined Ben Hall: yet he had never shot a man before. Three men terrorized 60 people on the open road, and not one made an attempt to escape. One man kept those 60 people impotent while his two friends were engaged with the police and the mail-coach. Yet the victims were presumably not all cowards, and men of their stamp were not slow to defend their own homes when a larger gang made night attacks. The fear of treachery seems to have been responsible for their conduct. The bushranger, as has been said above, was hand in glove with many small farmers and their kin, and no one of the 60 could be sure that his next neighbour was a *bona fide* prisoner. And the tales of oldtime bushrangers stood their successors in good stead; the

traditional reward of any attempt to escape was death. So Gilbert, who had never till that day killed a man, lost none of his terrifying power by that abstinence: he was feared as the successor, and possible rival, of Donohoe the stripper and Jefferies the woman-murderer. When men defied the robbers boldly, they were often allowed to go unharmed past their less fortunate fellows. Not long after the Jugiong affair the same three were holding the same main road not many miles out of Goulburn, between that town and Sydney. A coach and several drays had been 'stuck up,' besides the usual miscellaneous crowd of passers-by. Then came along William Macleay in a buggy; seeing the bushrangers, he told his boy to drive slowly on, while he walked by the horse with a loaded rifle in his hand. The gang at once rode off into the bush, and did not disturb him until, half a mile farther on, he got into his buggy again: then they fired a couple of shots, but disappeared again directly he returned their fire. Yet not even this proof of their desire for a peaceful life could destroy their reputation for bloodthirstiness; Macleay actually stopped on his road to talk to the prisoners, but found them too cowed even to answer him, much less to make any attempt at escape.

It is at first sight remarkable that so quiet and profitable a trade was ever given up. Yet in the end nearly every man engaged in it died by violence—a few executed, most shot down in the bush by police or amateur trackers. For, one and all, they made the fatal mistake, grew careless of human life, began to kill recklessly, and so exasperated the police into energetic pursuit. Ben Hall's gang for 2½ years found the police quite harmless, and baffled or evaded them with ease and a good deal of pleasant humour: nor did the shooting at Jugiong much disturb these relations. But when, early in 1865, one of the gang shot a constable at Collector, and within six weeks or so four others were wounded in skirmishes, the temper of the police changed. Then tracking began in serious earnest. Then we hear that 'the bush was alive with police' about their haunts. By the middle of May both Gilbert and Hall had been shot, the latter receiving volley after volley from his pursuers—they admitted having fired thirty shots, and fifteen were found in his body.

The career of Hall's gang has been discussed at length because it illustrates clearly the attitude of the public at large towards bushranging when not combined with brutality. We must now return to a more chronological narrative. The gold-robbing epoch began, as might have been expected, in Victoria, where ex-convicts from Tasmania found profitable employment on the roads from Buninyong and Bendigo to Melbourne; one daring trio even boarded a vessel (the *Nelson*) in Hobson's Bay and stole from her 8183 oz. of gold, and another in 1854 took over £15,000 from the Bank of Victoria at Ballarat. The most notorious of these Tasmanian criminals was Frank McCallum (q.v.), better known as Captain Melville. But distances were short in Victoria, and in a few years police protection along the main roads was ample, while the small farmer class from whose families the most notorious gangs of this epoch were recruited hardly existed in the southern gold-bearing area.

In New South Wales the epoch began with the exploits of Frank Gardiner, which are related under his name. Both he and his first companion John Piesley were 'colonially convicted' men: so was John Gilbert, Gardiner's right-hand man after Piesley was hanged on 25 March 1862: but the recruits who joined Gilbert after Gardiner had escaped to Queensland—Ben Hall (q.v.), John O'Meally, John Dunn, Michael Burke, John Vane—were either themselves respectable farmers to begin with or the sons of such men. O'Meally and Dunn were mere boys when they joined the gang. Raids and robberies innumerable were attributed to the Gilbert-Hall party, their names being used by every amateur highwayman who 'bailed up' a solitary traveller. Their chief exploits, however, are well authenticated, and included the theft of well-known race-horses from half a dozen stations in the Lachlan valley, raids on Carcoar, Caloola, Trunkey, Canowindra and stations in the vicinity (all during the autumn and winter of 1863): the famous visit to Bathurst on 23 October, undertaken simply because a young Bathurst resident had dared them to go there: the attack, already mentioned, on Keightley's house near Rockley, in which Burke was killed and after which Vane surrendered: a raid (19 November 1863) on Goimbla station near Forbes, in which O'Meally was killed: and then, in the spring and summer of 1864-5, a long series of mail-robberies and 'stickings up' on the roads west and south of Goulburn. This long-lasting impunity, and the complete failure of the police to inflict any injuries on the gang (for Burke and O'Meally were killed by settlers whom they were attacking), drove the government to pass hastily through the Sydney legislature a felons' apprehension act (12 April 1865), under which bushrangers might be proclaimed outlaws and killed at sight if they would not surrender, and all who harboured them or aided them with information or otherwise became felons. On 10 May Gilbert, Hall and Dunn were so proclaimed. But Hall had already been killed on 5 May near Forbes: Gilbert was betrayed by Dunn's grandfather and killed on May 13: Dunn, who was wounded when Gilbert was killed, but escaped to the lower Macquarie district and for eight months worked as a horse-breaker, was caught near Dubbo early in January 1866 and hanged on 19 March. From February 1863 to April 1865 this gang had committed 10 mail-robberies, stolen 23 race-horses for its own use, raided 21 stores and private houses—and killed two men.

A bushranger of a very different type was Daniel Morgan, who was active in the southern districts of New South Wales, along the Murray while Ben Hall's gang was harrying the centre. Though never a convict—he was born at Campbelltown in New South Wales in 1830 and from 1847 to 1854 was a stockman on a Murrumbidgee station—he rivalled the worst of the convict bushrangers in brutality. He shot down unarmed and sleeping men, and tortured women. His criminal career began near Wagga soon after the Eugowra robbery, included raids on stations and isolated inns between Tumberumba and Deniliquin, and ended when in the autumn of 1865, in response to a challenge from the Victorian police, he crossed the Murray and held up traffic and station-owners between Wangaratta and Benalla. On 8 April he visited Peechelba station, some 15 miles NW. of Wangaratta, bailed up the entire household for the night, and was shot next morning by a station hand. His head was cut off and sent to Melbourne to be examined for scientific purposes by the university's professor of physiology.

The Clarke brothers operated between Goul-

burn and Monaro in 1865-7. Their family history is remarkable. The father died in gaol while under arrest for shooting a black tracker. Of four uncles, one was shot by police in a raid, two were convicted of highway robbery, and the four were accessory to a murder of policemen. The family lived by cattle-duffing and horse-stealing until the police tried to arrest them, and then took to bushranging. The second brother, James, was convicted of receiving property stolen by the Ben Hall gang in a mail-robbery. Thomas, the eldest, escaped from Braidwood gaol—to which he had been committed on a charge of robbery—early in October 1865, and within the next eight months stole three race-horses, robbed a post-office, three stores, and many travellers on the roads between Braidwood and Moruya, stuck up the Araluen mail, and killed a policeman. At the end of May his youngest brother John joined him in the bush, and the pair in 11 months stuck up six mail-coaches, robbed travellers innumerable (most of them Chinese), and killed four special constables. They were not always alone in these crimes: Patrick Connell, an uncle, frequently accompanied Thomas, and in the later months William Scott and James Griffin were members of the gang: Scott was killed by the Clarkes, and Griffin seems to have betrayed them. After Thomas Clarke's murder of the policeman on 9 April 1866 he and Patrick Connell were proclaimed under the felons' apprehension act: and after the murder of the special constables on 5 January 1867 a reward of £5000 was offered for their capture—a distinction which they promptly celebrated by sticking up four mail-coaches within a fortnight. On 27 April, however, they were surrounded at night in a settler's hut by 15 troopers and in the afternoon of the next day surrendered without a struggle. They were tried in Sydney, and hanged on 25 June.

Isolated cases of bushranging continued to occur for several years after the execution of the Clarkes, but few are worth notice. The best-known of the later criminals was Frederick Ward ('Captain Thunderbolt') an ex-convict born at Windsor, New South Wales, who from December 1864 to May 1870 lived at large upon the area from Newcastle north to Manilla, robbed many mails and stuck up many travellers, and was shot on 25 May: he is usually reckoned the last of the New South Wales bushrangers. In 1873 an official return showed that 23 men were in gaol who between 1864 and 1869 had been sentenced to various terms for highway robbery. The other colonies were less troubled. In Queensland only one 'professional' bushranger appeared—Alpin Macpherson, better known as the 'Wild Scotchman,' who in the early sixties alleged that he had been a member of Ben Hall's gang, but in fact did very little except stick up half a dozen travellers, allow himself to be captured, escape from custody, and get caught again. In Victoria, after the capture of McCallum, the only bushranger of note was Harry Power, an Irishman who reached Victoria at the beginning of the gold-rush, took to horse-stealing in 1855, was gaoled therefor and served the greater part of a 14 years' sentence, but early in 1869 escaped and took to the bush in the Beechworth district. Except for a short raid into New South Wales as far as Adelong, he confined himself to this area, and was captured in his camp near the head of the King River on 27 May 1870. He served out a 15 years' sentence, was engaged after his liberation to add verisimilitude to the exhibition at Melbourne and Sydney of the pseudo-convict hulk *Success*, and was drowned in the Murray during a holiday trip on 7 November 1891.

From 1870 onwards Australia was on the whole free from bushrangers for about eight years. Then, out of a clear sky, there burst upon Victoria the first of the astounding feats of the Kelly gang. Ned Kelly, the leader of this gang, had consorted with Power, who thus became a link between the bushrangers of the sixties and the solitary eruption of the late seventies. For the history of the Kelly gang see KELLY, EDWARD. Here we need only note that its appearance and exploits were an isolated and extremely melodramatic phenomenon: they afforded, indeed, the material for the second purely Australian melodrama, of which Ned Kelly is the hero. But no possible stage production could equal the sensationalism of the gang's actual last moments, when they were trapped in the inn at Glenrowan. The leader, walking calmly among his enemies in impenetrable armour, fired on for half an hour by ten of them, and brought down at last with four wounds in the legs—which he had neglected to armour: his two desperate comrades, answering sullenly from their refuge the fire of 50 police concentrated on the little weatherboard hotel: the crowd of spectators, mainly sympathizers with the gang, and including one of the Kellys' sisters: the demands of the baffled assailants for a 12-pounder cannon and an electric searchlight: the final catastrophe, when the building was set on fire, and among its ashes were found the bodies of the two defenders, so burnt as to be hardly recognizable for human remains—the crudest of Elizabethan playwrights could have conceived nothing more bizarre. In such fire and fury perished the last of the bushranging gangs, and left to Australia traditions of adventure that might have been dangerously attractive, had not the brutal lives—and deaths—of most of the pseudo-heroes robbed them of their glamour.

See Boxall's *History of the Australian Bushrangers* (1924 edition) and Charles White's *History of Australian Bushranging* (1906).

Bustards. birds of the family Otididae, inhabiting open country throughout the old world. The Australian species, *Eupodotis australis*—which is almost universally known as Wild Turkey or Plain Turkey—is widely spread over the continent, particularly in the inland districts, but does not occur in Tasmania.

The bustard feeds largely on insects, especially grasshoppers, so that it is of great value to the agriculturist. By destroying these insects in their inland nurseries it probably often prevents the formation of large swarms which, when once formed, would undoubtedly travel towards the cultivated coastal regions in search of food. Unfortunately, its fine edible qualities make it much sought after by sportsmen, and its terrestrial habits render it a comparatively easy prey to the fox, which makes numerous captures of sleeping birds. It is rapidly becoming rare in all settled districts.

The cock bustard attains a large size, sometimes weighing as much as 18 lb. When displaying before the hen he behaves much like a domestic turkey-cock, elevating his tail like a fan, spreading his wings, erecting the long crest feathers on his head, and inflating with air a sac in the throat so as to spread out the elongated feathers on the front of the neck. The female lays one reddish-brown, mottled egg on the bare ground; occasionally two are laid.

These fine birds were first met with by Captain Cook on 23 May 1770, on the Queensland coast a little north of the present town of Bundaberg; 'upon the shore' he notes 'we saw a species of the bustard, one of which we shot, it was as large as a turkey and weighed 17½ pounds. We all agreed that this was the best bird we had eaten since we left England

Wild Turkey.

and in honour of it we called this inlet Bustard Bay.' Incidentally the presence of bustards on the coast indicated that the area farther inland was at the time drought-stricken; in normal years the bustards are not found on the coast.

W.B.A.

Butcher-birds, perching birds belonging to the genus *Cracticus,* confined to New Guinea, Australia, and Tasmania. The genus was formerly placed in the family Laniidae (shrikes), to which the butcher-birds in other countries belong, but is now generally recognized as closely related to the Australian magpies (*Gymnorhina* and *Strepera*), and is placed in the family Streperidae.

Butcher-birds are largish birds (though smaller than magpies), with handsomely marked black, white, and grey plumage and stout bills with a hook at the end of the upper mandible. They feed on large insects, lizards, mice, and young birds, and derive their name from their habit of hanging up the bodies of any victims which cannot be swallowed immediately by sticking them on spiny twigs in some convenient tree.

The nests of butcher-birds are large, open, cup-shaped structures placed in bushes or small trees, and the three or four eggs are yellowish-brown in ground-colour, with brown spots and blotches. The commonest species throughout southern Australia, and the only one found in Tasmania, is the Collared Butcher-bird (*C. torquatus*), whose cheerful, rollicking call bears a slight resemblance to the laugh of the kookaburra, though it is much more melodious; this has given rise to the name of little or Derwent jackass by which the collared butcher-bird is frequently known.

The larger and handsomer Black-throated Butcher-bird (*C. nigrogularis*) is found through-

Black-throated Butcher-bird.

out the greater part of the continent, but is more partial to the inland districts. The other three species are confined to the north, the range of two of them extending to New Guinea. Of these the Black Butcher-bird (*C. quoyi*), found in northern Queensland and the Northern Territory, is of interest because, while the adult birds are entirely black, the young are either black or reddish-brown. How long the brown plumage is worn before the black is attained is not known, but brown birds are frequently found breeding.

W.B.A.

Butter. See Dairying.

Buttercup. This name (as well as that of 'crowfoot') is popularly given to several species of *Ranunculus,* a genus abundant in temperate and cold regions both north and south of the Equator. It belongs to the family Ranunculaceae, consisting of annual or perennial herbs. Nine species are indigenous to Australia. They have white or yellow petals (the calyx falls early), each with a nectary at its base. *R. Millani* and *R. anemoneus* are white-flowered species, conspicuous on swampy ground or lake shores in the Australian Alps *R. Gunnianus,* with yellow flowers, is also an alpine species in Victoria and New South Wales, and extends to Tasmania. *R. aquatilis,* a species with floating stems and white flowers, is found in streams and pools in the coastal districts, from New South Wales to South Australia.

Butter-fish, a popular name for several species that are as widely different in appear-

ance as they are in affinities. In New South Wales and Queensland the name is applied to two allied fishes, the Striped Butter-fish (*Scatophagus multifasciatus*) and the Spotted Butter-fish (*S. argus*). The former is a deep, compressed fish with minute scales, silver in colour, with irregular vertical bars and spots of dark green; these vary so greatly that their different patterns have been considered to be characteristic of distinct species. The spotted butter-fish is golden brown, covered with rounded chestnut-brown spots. Both species are plentiful in warmer waters, and the latter ranges northward to China and India. Notwithstanding their vernacular name, they are rather despised as food-fishes.

The butter-fish of South Australia is one of the most important market fishes of that State, being identical with *Sciaena antarctica*, the Jewfish (q.v.) of New South Wales fishermen. In Western Australia the name is applied to the common *Pentapus vitta*, which though small is fleshy, and related to the breams. In New Zealand the name is given to one of the Parrot-fishes (*Coridodax pullus*), an important species in the markets, growing to 20 inches in length. In other parts of the world the name is equally popular; it is indiscriminately bestowed upon fishes both large and small, useful or valueless for the table—and they seem to merit the appellation no more than do the Australian representatives.

A.R.McC.

Butterflies, vernacular name of a group of the order Lepidoptera (q.v.) and sub-order Heteroneura, insects with scales (modified hairs) on their wings and more or less swollen terminations to their antennae; hence the group is usually known as Rhopalocera (club-horned). Some moths, including a few Australian species, also have clubbed antennae; but all these have a frenulum, and can thus be distinguished from all Australian butterflies except *Euschemon rafflesia*, which is discussed below. The popular belief that butterflies fly only during the day and moths only at night is inaccurate, since some butterflies appear only at dusk and many moths fly by day. With a few exceptions—all mentioned below—Australian butterflies, when at rest, fold their wings erect above the back.

Australia possesses 332 species of butterflies, classed in 112 genera and six families, whose characteristics are:—

A. Antennae wide apart at base: hind tibiae usually with medial as well as terminal pair of spurs: fore-wing and all veins from base or from cell, none stalked with vein R_5 beyond cell . . . . . Hesperiidae.

B. Antennae close together at base: hind tibiae with terminal pair of spurs only: fore-wing with one or more veins stalked with vein R_5 beyond cell:

a. Precostal spur of hind-wing absent. . Lycaenidae.

b. Precostal spur of hind-wing present:

(1) Front pair of legs perfect in both sexes:

i. Precostal cell of hind-wing present: vein 3A of hind-wing absent . . Papilionidae.

ii. Precostal cell of hind-wing absent: vein 3A of hind-wing present . . Pieridae.

(2) Front pair of legs imperfect in male only. . . . . Nemeobidae.

(3) Front pair of legs imperfect in both sexes. . . . Nymphalidae.

The Hesperiidae (skippers), so called from their jerky manner of flight, comprise more than one-fourth of the butterflies of Australia. On account of their small size and usually dull colour they do not often come under notice, while some are of great rarity. The larvae are smooth, with a prominent head, and live during the day-time in a curled-up leaf. The pupae are smooth, often with prominent head projections, and are found in leaves that are either curled-up or drawn together by silken threads. Of the 92 species the most remarkable is the large Regent Skipper (*Euschemon rafflesia*), found along the east coast as far south as Port Macquarie. The male butterfly (which is black, with semihyaline golden spots and greenish markings beneath) has a strong frenulum in the male; the female (similarly coloured) couples its wings in the usual butterfly manner, and has no trace of a frenulum. This species forms a connecting link between butterflies and moths. A few archaic Australian skippers rest with wings flat instead of raised. These are all most interesting species, generally of larger size than the rest of the family, in life possessing brilliant fiery eyes. A small group of robust insects (Ismeninae) is represented by six species, including *Hasora haslia* and *Parata hurama*, the latter with a broad white band on the hind-wing beneath. Another group (Erynninae, of Oriental origin) includes 26 Australian species, found chiefly in the north, where their larvae are destructive to palms and similar plants: these are usually of some shade of brown, with yellow or orange markings, and include the tiny *Padraona flavovittata* and the much larger *Cephrenes trichopepla*, whose larvae feed respectively on couch-grass and on palms.

More than half the recorded species belong to endemic genera; some are found in Tasmania, and most in southern and south-eastern Australia, but a few extend as far north as Cairns. The beautiful *Anisynta argenteo-ornata*, with its silvery splashed underside, from the islands of Western Australia; the rare *Mesodina croïtes*, from the desert near Geraldton (only four specimens are yet known); the handsome *Hesperilla picta*; the dingy *Toxidia peroni*, and the large *Trapezites symmomus* (plate xi, fig. 33)—all belong to this group. Numerous species of *Trapezites* and *Hesperilla* occur in the mountains of Tasmania and south-eastern Australia.

The Papilionidae (swallow-tails) of Australia, though not so brilliant or numerous as in the tropics, are yet sufficiently so to attract notice in the semitropical parts of the continent. The handsome black-and-green *Troïdes priamus* of the Moluccas is represented here by four distinct sub-species; *T. richmondius*, accompanied by its larger sombre black-and-white female, is frequently seen in the scrub areas of New South Wales and southern Queensland, and the larger *T. euphorion* is well known at Cairns, Kuranda and Cooktown, where it is attracted by the flowers of the scarlet hibiscus. The brown-and-cream *Papilio sthenelus* is more abundant inland than on the coast, but stray specimens are to be found throughout Australia. A small black-and-white citrus *Papilio* (*P. anactus*), endemic in Australia, is common in the orchard districts of New South Wales, and is now extending its range into Victoria and northern Queensland. The larger citrus *Papilio* (*P. aegeus*) has a much more extended range throughout eastern Australia, and is plentiful in Queensland, where a very occasional white form of the female has been taken. Through-

out New Guinea and the Solomon Islands many varying forms of this handsome butterfly occur. *P. egipius*—intermediate in size between *P. aegeus* and *P. anactus*, and somewhat resembling the former—is only found in northern Queensland, where it usually flies among tall trees. Among tailed species of *Papilio* the Australian form (*P. joësa*) of the Moluccan *P. ulysses*, with its brilliant black-bordered blue wings, makes a glorious sight as it flies above the densely wooded creeks of northern Queensland. Two similarly-shaped brown-and-white swallow-tails, *P. capaneus* of Queensland and *P. canopus* of the Northern Territory, are most interesting species. Our only two representatives of the long narrow-tailed swallow-tails are *P. parmatus* and *P. leosthenes* of northern Queensland (the latter also found on the northern rivers of New South Wales), both of which sometimes gather in numbers on a damp spot on a road or creek-bed. *Papilio macleayanus* (plate xi, fig. 32) is the only swallow-tail found in Tasmania, whence its range extends along the coast as far as Cape York. It has a swift flight when disturbed, and often soars round the tops of tall eucalypts, where its green markings can be seen distinctly in the sunshine. Of the remaining Australian swallow-tails the black-and-blue *P. choredon* is a frequent visitor wherever the camphor laurel is grown as an ornamental tree: its allied spotted species, *P. lycaon*, *P. macfarlanei* and *P. ligatus*, belong to the more tropical parts of Australia. The red-bodied *Menelaïdes queenslandicus* (the Australian form of *M. polydorus*) is found in northern Queensland, but the somewhat similar *Eurycus cressida* is taken as far south as Sydney, and is abundant in the Northern Territory: the female of *E. cressida* is almost transparent, and on the wing looks like a worn and wasted male.

With four exceptions the Papilionidae of Australia have reached the continent from New Guinea by way of Cape York, and are gradually extending south along the east coast; this progress is helped by the use of their food-plants as ornamental or economic trees. Some species have not yet come farther south than the scrub districts of Cairns; others come to the northern rivers of New South Wales, and a few extend south of Sydney. All have a more or less extended range in the Indo-Malayan region, and forms of some of them occur in India and southern Japan. Of the four exceptions to the invasion from New Guinea, *P. macleayanus* has been long in Australia, and has an interesting representative, *P. weiskei*, in the mountains of New Guinea: *P. anactus* stands by itself, there being nothing like it outside Australia: *P. leosthenes*, though so similar to the long narrow-tailed swallow-tails of the East, is really a connecting link between 'fluted' and 'kite' swallow-tails: *P. sthenelus* differs from all others of the family in frequenting the drier interior instead of the coastal regions, and probably reached Australia from Timor.

The Pieridae (whites and yellows) are not so conspicuous a feature of the landscape as in some countries, though occasional flights of some two or three species have been recorded. The beautiful *Delias*, with their showy red-and-yellow markings beneath, are much more conspicuous in the cabinet than when soaring leisurely round the tops of a flowering tree; but, when a number of them gather round a flowering *Duranta* shrub in Queensland, they attract immediate attention. *Delias harpalyce*, the largest species, is confined to south-eastern Australia; it has bright yellow splashes on the fore-wing beneath, and a band of broad scarlet spots on the hind-wing beneath. As usual in this family, the upper surface of the female is much darker than that of the male. Dainty little white *Elodina* species are often very plentiful in the north, flitting about the trees, and occasionally immense flights of *Anaphaeis teutonia* may be seen travelling in the one direction; such flights continue even over the sea at some distance from land, and large numbers may be washed ashore on the beaches. *Appias ega* and *Huphina scyllara* are widespread northern species (sometimes extending southwards), and three other species of *Appias* occur sparingly in the north. The large yellow *Catopsilia* are plentiful in northern Queensland and the Northern Territory, but are only occasional visitors as far south as Sydney, where the white species are much oftener seen—sometimes in migratory flights. The bright little sulphur-yellow genus *Terias* is represented in Australia by eight species, only one of which, *T. smilax*, reaches the extreme south. The largest is *T. sulphurata*, a form of the wide-ranging *T. hecabe*: *T. lineata*—and sometimes *T. herla*—have the hind-wing beneath suffused a delicate pink.

The Lycaenidae (blues, copper and hairstreaks) comprise slightly more than one-third of Australian butterflies. Generally of small size, they are unrivalled for their dainty appearance, and are often gems of great beauty. They are the only group that is found throughout Australia wherever vegetation exists. Some species occur on the seashore; one is the only butterfly seen in any number near the cairn on Mount Kosciusko; the larvae and pupae of others are found associated with ants. These larvae, through certain dorsal glands, secrete a fluid that is much sought after by ants (especially those belonging to the genera *Camponotus* and *Iridomyrmex*); the ants, therefore, house the larvae in order to gather the secretion and, in return, look after both larvae and pupae and protect them from enemies. During the day the larvae are found hiding in ants' nests or tunnels, or under pieces of bark, or in holes and cracks in trees. The writer ventures the opinion that in some cases the ants collect the eggs and take them to their nests, besides guiding the larvae to and from their food after they have emerged. In some few cases it is suggested that the ants feed the larvae.

Though much time has been spent in the study of this family, its divisions cannot yet be said to be wholly satisfactory. The largest species is the robust *Liphyra brassolis*, which seems quite out of place amongst its dainty relations. This orange-and-brown species is found in the north; its larvae live in the nests of the green tree-ant, and probably feed on the ants' larvae and pupae, being themselves protected by a chitinous armour-plate which their hosts cannot penetrate. The group of hair-streaks is not well represented in Australia, though some remarkable forms are found in the north—e.g. the long-tailed *Bindahara isabella*, and species of *Deudorix*, *Rapala* and *Hypolycaena*. The genus *Ialmenus*, which occurs almost throughout Australia, is the best-known. In Victoria, New South Wales and southern Queensland the well-known *I. evagoras* is to be found, sometimes in numbers, flying round acacias, on the leaves of which its larvae feed. *Pseudalmenus chlorinda*, var. *zephyrus* (plate xi, fig. 31), a related species, is found in Victoria,

Life History of *Anaphaeis java*, var. *teutonia*.

1. Egg, 30 times natural size. 2. Larva, four times natural size. 3. Pupa, four times natural size. 4. Butterfly, thrice natural size.

with closely allied forms in Tasmania and New South Wales. The genus *Arhopala* contains several handsome insects, found only in tropical Australia. One genus of importance, *Ogyris*, is found both in the tropics and in more temperate latitudes; with the exception of one New Guinea species all the described forms are from Australia. For brilliancy of blues and purples, and occasionally of green, these butterflies are unrivalled; they are not so rare as is generally supposed, but only the expert succeeds in obtaining them, since when seen on the wing they are usually far out of reach. The genus *Thysonotis* contains some very handsome species, of which one extends its range nearly to Sydney, though both species and individuals are more plentiful in the tropics. The genus *Miletus*, found throughout continental Australia, contains species of extremely brilliant colouring, especially on the under-side. Notable examples are *M. halyaetus* from Geraldton in Western Australia, with its silvery green under-side, and the copper-coloured *M. apollo* and *M. apelles*. Most Lycaenidae, however, are small and of a sombre blue. The little *Zizina labradus* occurs nearly everywhere in Australia, the larva's food-plant being clover, lucerne and allied plants; occasionally it may be found feeding on French beans. The somewhat similar, but larger and tailed, *Lampides boeticus* feeds at times on sweet peas. These are probably the only two butterflies that occasion any damage—and that only slight—to our garden plants.

The Nemeobidae are represented by two genera only, each containing a single species; both are found in northern Queensland.

The great family Nymphalidae has Australian representatives of six sub-families. The pupae of this family suspend themselves by the tail, and hang head downwards. *Acraea andromacha*, the only Australian representative of a group that has numerous species in Africa, has almost transparent fore-wings, and is marked with black spots. The sub-family Nymphalinae contains strong-flying robust species, usually with wide ranges through the east, and rarely with more than one species to the genus in Australia. *Argynnis inconstans*, still a rarity in collections, represents the fritillaries of Europe. In northern Queensland *Cupha prosope*, *Cethosia chrysippe* and various species of *Neptis* are not uncommon; the Australian Leafwing (*Doleschallia australis*) reaches northern New South Wales, and *Hypolimnas nerina* is sometimes found in Sydney, where the handsome *Eulepis sempronius* is seen every year. The only species that extend farther south are *Pyrameis kershawi*, which feeds on everlasting-daisies, and *P. itea*, which feeds on nettles; the former is closely allied to the 'painted lady' of Europe, and the latter is the Australian 'admiral.' The truly Pacific butterfly *Precis villida* is also an inhabitant of southern Australia. The sub-family Amathusiinae is represented by two species of *Taenaris*, with very large eye-spots on the hind-wings; these have only been caught on the islands in Torres Straits. A single species of the Elymniinae has been caught at Cape York.

The sub-family Satyrinae (browns) prefers the shade of gully and forest, and forms an important element in the Australian fauna; with the exception of *Melanitis* and *Mycalesis* in the north, and the smaller *Hypocysta* and *Yphthima* which extend farther into New South Wales, its species belong to endemic genera that are confined chiefly to the southern and south-eastern portions of the continent and to Tasmania. The genus *Tisiphone* contains an interesting assemblage of forms that may throw some light on the earlier physiographical changes of the east coast. *Xenica* and *Heteronympha*, with their allied genera, are generally of some shade of orange or brown; some have a wide range, others are not found below an elevation of 4000 feet. These genera have not yet been fully studied, but enough has been done to show that in some cases they have developed distinct local variations. *Heteronympha merope* (female shown on plate xi, fig. 30) from the east can readily be distinguished from the form found in the west, and the Tasmanian form presents special points of difference. The pretty little species of *Oreixenica* are common at high elevations in the Australian Alps; one species (*O. lathoniella*) is found near sea-level in Tasmania. *Nesoxenica* is the only genus confined to Tasmania; its single species (*N. leprea*) has developed two forms, of which that found in the centre and on the west coast is much brighter than the typical form from Mount Wellington.

In the sub-family Danainae the black-and-white genus *Euploea* has about 10 species, occurring chiefly in the north, though the common *E. corinna* is sometimes found near Sydney. The same distribution is true of the allied genus *Danaida*; two tawny species are common at times near Sydney and even farther south, and two others are rare visitors to Sydney, but all are more common as we go north. Both *Danaida* and *Euploea* belong to tropical groups which have invaded Australia—not to the older Australian fauna, which is represented by most of the satyrids and a large number of the lycaenids and hesperids.

Economic Importance:—Few Australian butterflies are destructive to cultivated plants, though the larva of *Papilio aegeus* infests orange-trees in New South Wales and Queensland, and that of the smaller *P. anactus* seems likely to become a serious pest in the orange groves of Mildura and Renmark on the Murray. Occasionally the caper and allied plants are defoliated by the larva of the White Caper butterfly (*Anaphaeis teutonia*), which appears periodically in immense swarms throughout eastern Australia, and is sometimes blown across the straits to Tasmania; there, however, it does not breed. A small lycaenid (*Zizina labradus*) attacks beans—and sometimes lucerne, peas, and other legumes—in the southern districts of Australia.

See *Australian Butterflies*, by A. S. Olliff (1889); *Victorian Butterflies*, by Anderson and Spry (1893); *A Guide to the Study of Australian Butterflies*, by W. J. Rainbow (1908); and *The Butterflies of Australia*, by Waterhouse and Lyell (1914), in which all known Australian butterflies are described and figured. G.A.W.

C

Caddis-flies, insects of the well-defined order Trichoptera, the closest relatives of which are undoubtedly the Lepidoptera on the one side and the Mecoptera and Diptera on the other. Fewer than 30 Australian species have been described, but more than 100 are known to exist in various collections. They are for the most part not unlike small moths; but only occasionally are the wings clothed with scales, their usual covering being abundant hairs, as the name of the order indicates. They are also recognizable by the specialization of their mouth-parts, which are so far reduced as to be of no use to the imago, except for the occasional lapping-up of dew or water; the only well-defined parts are the labrum and the two pairs of palpi. The wing-venation is on the same plan as that of the Mecoptera; but the first cubitus is forked, and cross-veins are restricted to a few places, where they are of special advantage for the bracing of main veins. The wing-venation also closely resembles that of the homoneurous Lepidoptera, from which it differs in having M_4 present as a separate vein in the fore-wing, but always absent in the hind-wing. The larvae (known as caddis-worms) resemble caterpillars, but lack all the pro-legs except the anal pair; they are familiar objects in all ponds and streams, dwelling for the most part in small portable houses or cases, which they construct out of sticks, leaves or sand-grains. Some, however, build fixed dwellings of pebbles, and some roam free on the river-bed. The pupa is a *pupa libera,* formed inside the larval case; it swims to the surface before disclosing the imago.

There are two well-marked sub-orders. In the sub-order Aequipalpia the maxillary palpi are five-jointed in both sexes. All the families are represented in Australia, except only the Molannidae; but few of the species in collections have been named and described. On the whole, they show a close similarity with the New Zealand forms, which are better known. Genera common to both countries are *Hydrobiosis* (Rhyacophilidae), *Polyplectropus* (Polycentropidae), *Hydropsychodes* (Hydropsychidae), and several common genera of Leptoceridae. Some of the loveliest of our caddis-flies are the sub-alpine species of the genus *Smicridea,* whose snow-white males fly together in thousands, resembling a miniature snow-storm. The commonest caddis-flies in Australia are the long-horns, members of the family Leptoceridae; of these, the dull-coloured *Notanatolica magna* is the largest and best-known. Numbers of males may be seen flying gracefully near still water in the springtime. Smaller species of similar habits, with very elongated and slender fore-wings, belong to the genera *Triplectides* and *Oecetis.* Plate xix figures two rare and handsome caddis-flies, *Stenopsychodes montana* (fig. 21) from the Blue Mountains, and *Macronema pulchripenne* (fig. 22) from Stanwell Park in New South Wales.

Notanatolica magna.

In the sub-order Inaequipalpia the maxillary palpi are five-jointed in the female, but only three- or four-jointed in the male. The sub-order contains three families. Few species have been described—all anomalous forms that are placed among the Sericostomatidae, but have little in common with more normal members of that family. Among them are the extraordinary *Plectrotarsus gravenhorsti* with its elongated beak, and the remarkable Marine Caddis-fly (*Philanisus plebejus*) whose larva forms cases out of coralline seaweed, and is found in many places along the coasts of Australia and New Zealand. Species of *Helicopsyche* make sand-cases in the form of a spiral shell; they are common objects attached to rocks in running streams. There are also some remarkable species with whorls of spurs on the tibiae, but these have not yet been named.

The families Phryganeidae and Limnephilidae, dominant in the northern hemisphere, appear to be absent from Australia.

See Ulmer in *Genera Insectorum,* fasc. 60, and *Arkiv. Zool.* x, 13.

R.J.T.

Cadell, Francis (1822-1879), born at Cockenzie near Prestonpans in Scotland, and educated in Edinburgh and Germany, in 1835 entered the service of the East India Company as a midshipman, and in 1840-1 took part in the first Chinese war. At 22 he was in command of a vessel, and between voyages devoted much study to shipbuilding and marine steam-engines. A visit to South Australia in 1848 interested him in the problem of navigating the Murray, Sir Henry Young (q.v.) having about that time offered a bonus of £4000 for the first two shallow-draught steamers of not less than 40-horse power that should be taken up-river from Goolwa to the junction of the Darling. This induced Cadell to return to Australia in 1850, and in 1852, accompanied by four gold-diggers, he navigated a canvas boat from Swan Hill to Wellington, voyaging thence in a stronger boat to Lake Alexandrina—1300 miles in all. Arriving in Adelaide, he joined William Younghusband in forming the Murray Steam Navigation Company; its first river steamer, the *Lady Augusta* (which was built in Sydney and engined by P. N. Russell & Co.), he himself took—along with a 100-ton lighter—from the Murray mouth to Swan Hill in a little more than three weeks (August 25 to September 17, 1853), having Governor Young aboard, and brought back the

first cargo of wool (441 bales) ever transported from the Riverina to Adelaide. For this achievement he was presented with a gold candelabrum worth 900 guineas, and the local legislature had a gold medal struck in his honour. He now commenced regular trading trips along the Murray, added the *Albury* and the *Gundagai* to the company's fleet, and sought on every trip to reach towns farther from the river-mouth. In October 1855 he thus reached Albury (1740 miles from Goolwa), and in 1858 Gundagai on the Murrumbidgee (2000 miles from Goolwa). In 1859 he ascended the Darling to Mount Murchison near Menindee. Valuable as this work was for Australia, it was quite unprofitable for Cadell; his company was never a success, and its collapse ruined him. During the Maori war of 1860-5 he was employed in the transport service; then he settled for a time at Mount Murchison; then, embarking on pearl-fishery along the northern coasts of Australia, he explored the Gulf of Carpentaria and in November 1867 discovered the mouth of the Roper River. Ill-luck still pursuing him, he began to trade with the Dutch islands of the Arafura Sea; and, while voyaging from Amboina to the Kei group, was murdered by his native crew in June 1879.

Caesalpinia, a genus of the family Leguminosae, consisting of shrubs, trees, or climbers, chiefly tropical. The flowers are yellow; pod oval and compressed; leaves with numerous leaflets. The seeds of *C. bonducella,* a prickly climber, are known as 'nicker nuts' or 'Molucca beans;' in India as 'fever nuts' or 'physic nuts.' They are very bitter and largely used in India as a tonic or febrifuge. In Amboina the roots are used for dyspepsia and the seeds as an anthelmintic. The roots of *C. nuga* also possess medicinal properties.

Cairns, Sir William Wellington (1828-1888), son of William Cairns of Cultra in county Down, Ireland, and half-brother of Disraeli's lord chancellor Earl Cairns, was born in 1828, and trained for the civil service. After some eastern travel he entered the Ceylon civil service in 1852, was made the colony's postmaster-general in 1864, and returned to England in 1866 to commence a round of colonial governorships—becoming lieutenant-governor of Malacca in 1867, of St. Kitts in 1868, of Honduras in 1870, and governor of Trinidad in 1874 and of Queensland in 1875. In 1877 he was transferred to South Australia, but his commission as governor did not reach the colony until after he had left it, so that he ranks officially as administrator. His transference to Australia had been necessitated by ill-health due to the West Indian climate, but Queensland did not cure him, and his tenure of the South Australian post lasted less than two months (24 March to 17 May). He then retired from the colonial service, and died in England on 7 July 1888. (C.M.G., 1874; K.C.M.G., 1877.)

Caley, George (1775-1829), was born at Craven in Yorkshire; but his father, a horse-dealer, moved to Middleton near Manchester while Caley was still a small boy, and for a short time he attended the Manchester Free Grammar School. Following his father's trade, he found that farriery included some knowledge of plants, and took up the study of botany with ardour. An application to Sir Joseph Banks resulted in an appointment in 1794 to Kew Gardens; the drudgery tried Caley's restless disposition, and he went back to Lancashire, but returned to Kew in 1798. Later in that year Banks made him his own botanical collector in New South Wales, procured him a free passage in the transport *Speedy,* and introduced him to Philip Gidley King, who was travelling in the same vessel to succeed Hunter as governor. Leaving England on 12 November 1799, Caley reached Sydney on 15 April 1800, and soon found a home at Parramatta; there a botanical garden was marked out, which, with Colonel Paterson as director and Caley as superintendent, made such good progress that in 1802 François Péron, a French naturalist then visiting Sydney, was delighted with the collection of rare and beautiful plants, and spoke of Caley as enlightened, indefatigable, and modest. Caley's house and rations were supplied by the government, but his salary was paid by Banks, and he kept to himself as much as possible the discoveries he made and specimens he collected, considering himself Banks's employee. This secrecy annoyed King, and he complained again and again to Banks about it. The friction was increased by Caley's character; Banks described him before his departure for Australia as 'young, full of health, and abounding with zeal'—a zeal that probably accounts for the impatient demands on King which made that harassed governor mournfully deprecate 'Caley's abuse.' The botanist, on the other hand, complained to Banks of King's dilatoriness and Marsden's 'affronts,' and was soothingly warned that 'Some ill-treatment we all must endure. I hope your share of it is not greater than mine has been at your time of life.' Caley's love affairs were also worrying to high officials; he was very anxious to marry a convict woman who had come out in the *Speedy,* and afterwards transferred his affections to Margaret Catchpole (q.v.).

In March 1801 King sent Caley with Grant and Barrallier (q.v.) in the *Lady Nelson* to Western Port on Bass Strait; several collections of plants were made, but Caley managed to acquire them all, and would not give them up. Still, King admits that he 'behaved extremely well, and is much regarded by Lieutenant Grant.' One voyage, however, satisfied his love of the sea, and thenceforth (except for a trip to Tasmania in 1805) he confined himself to exploration by land. In 1802 he made several excursions to the foot of the Blue Mountains, and once at least saw from Mount Hunter behind Camden a landscape of wooded hills and rocky valleys that made him believe the ranges were not impassable, though probably difficult in wet weather. King, who was at the time sending Barrallier into the range behind Picton, could get nothing out of him: 'what he has done remains secret.' But in November 1804 'four of the strongest men in the colony, who had been accustomed to live in the woods' were allowed to accompany Caley on a journey intended to pierce the range west of Windsor. He made west from Grose junction on the Hawkesbury, crossed the Kurrajong ridge and Mount Tomah, and in 12 days had reached Mount King George (which he named 'Mount Banks'); there he came out on an inaccessible valley—the Grose opposite Govett's Leap—and his party refused to go farther. If he had turned northwards and rounded the head of the valley, he would have crossed the range with little difficulty. His track (which is made certain by his own tracings and outlines of views obtained

en route) coincides very nearly with the eastern section of 'Bell's Line,' so named from the surveyor who afterwards laid it out as an alternative route from Hartley to the coast.

For the time, however, even he was convinced that the hills were impassable, and contented himself with botanizing in the Nepean valley. In November 1805 he paid a short visit to Hobart (via Norfolk Island) and collected plants, a wombat and a porcupine. In 1806 he was again exploring the Picton country, and formed plans—which he could never carry out, because neither King nor Bligh gave him sufficient help—to explore (*a*) the Nepean gorges between Penrith and Camden, (*b*) the rough country south of Mittagong towards Jervis Bay. In August 1808 Banks, on the ground of his own failing health and eyesight, terminated Caley's employment but offered him a pension of £50 a year, with leave to stay in Australia or return to England at his choice. Caley preferred to return, and left Sydney in H.M.S. *Dromedary* on 12 May 1810, taking with him (much to Banks's subsequent embarrassment) an aboriginal named Dan. In England he settled for a time at Manchester, but in 1816 was made superintendent of the botanical gardens at St. Vincent in the West Indies; returning to England in 1823, he settled in Bayswater, and died there on 23 May 1829.

His temperament has already been described; no better evidence of it is needed than his long letter to Banks describing the Bligh mutiny, and commenting caustically on both parties. As a botanist, though his results were never published and we know practically nothing about them, he was much respected by his contemporaries; Cunningham calls him 'accurate, intelligent and diligent,' and Brown 'most assiduous and accurate.' He collected plants for Banks, but considered his other specimens his own, so that in 1818 he sold to the Linnean Society a large collection of quadrupeds, birds and reptiles, and after his death his collection of Australian timbers was presented to the same society by his executors. A genus of Australian orchids and many species of plants bear his name, as well as a hill in the Peel Range, New South Wales. The name 'Caley's Repulse,' given to a cairn near Linden on the Blue Mountains by Macquarie, is certainly a misnomer; Caley was never on that ridge.

Callicarpa, a widespread genus of the family Verbenaceae, consisting of shrubs, more or less woolly with star-shaped hairs, and often marked with resinous dots. In the flowers the calyx is truncate; corolla with a short tube; stamens 4-5, shortly protruding; fruit a small succulent drupe of 4 distinct 1-seeded nuts. *C. longifolia* is the 'chukin' of the aborigines near Cairns in Queensland. The bark is chewed by Japanese on the Johnstone River as a substitute for the betel leaf. *C. pedunculata* is an ornamental shrub, cultivated in gardens.

Callicoma, a genus of the family Cunoniaceae, two species of which are endemic in Australia and one in New Caledonia. The sepals are 4-5, free; petals obsolete; fruit a small capsule separating into distinct carpels opening along the inner edge; seeds more or less covered with tubercles. *C. serratifolia*, a tall shrub or small tree, has large leaves with saw-like teeth and dense globular heads of flowers resembling those of many Acacias. The early colonists called it 'black wattle,' from its dark bark, and its use for the frame-work of their wattle-and-dab huts. The name (which persists in Blackwattle Swamp, Sydney) is now exclusively associated with the genus *Acacia*. The 'saw-leaved' *Callicoma* has a close-grained timber, of a pinkish colour when fresh, which works to a nice smooth surface. It is occasionally used for small articles in wheelwrights' work, but rarely attains a large size. The saplings split easily, and have been used for basket-making.

Callicoma serratifolia.

Callistemon, a genus of the family Myrtaceae, endemic in Australia, consisting of shrubs or small trees (commonly known as bottle-brushes) with flat or cylindrical leaves and showy greenish-white, pale yellow, or crimson flowers, in dense cylindrical spikes. The flowers are borne on the tips of the branches; but the shoot continues its growth, and in the following season a new flower-spike is formed at its apex, a foot or more higher up the branch. The calyx-tube is bell-shaped, with 5 deciduous lobes; petals 5, orbicular; stamens numerous, free or shortly united at the base in a ring; fruit a capsule opening at the top, closely appressed to the branch. The fruits are persistent, and their age may be computed by counting the clusters, commencing at the base of the stem. As the seeds do not reach maturity for several years, this character is of service to the collector in securing ripe seeds. The name 'bottle-brush' is also occasionally applied to the Banksias (q.v.).

C. lanceolatus, the common Red Bottle-brush ('marum' of the aborigines) is found in Victoria, Queensland, and New South Wales, and is plentiful in swamps in the Port Jackson

district. Under cultivation it displays great variation in habit, height, foliage, and shade of red. *C. salignus* (White Bottle-brush, 'unoyio' of the aborigines) has a hard, close-grained timber with a reputation for durability underground. *C. viminalis* (Drooping Bottle-brush), a tree reaching 60 feet in height, has a tough timber extensively used for knees and braces of boats.

White Bottle-brush.

Callitris, a genus of the family Pinaceae, consisting of coniferous trees, commonly known as Cypress pines, and many with distinctive popular names. Indigenous to Australia, it ranges from Tasmania to the tropics, and from the coast to the interior. Most species exude a sandarac resin with a powerful aromatic odour; the bark of several is used for tanning. It is to a *Callitris* (probably *C. robusta*) that Paterson refers in 'The Man from Snowy River:'

> 'And down by Kosciusko, where the pine-clad ridges raise
> Their torn and rugged battlements on high.'

C. calcarata is the Black or Red Pine of New South Wales, Victoria, and Queensland. Twigs of this tree have been used as a vermifuge for horses. *C. robusta* (White or Common Pine) occurs in all the States. Its timber is resistant to white ants, and for this reason was largely used in the construction of railway stations on the transcontinental railway; being also, to a great extent, impervious to attack by the teredo, it is used for wharf-piles and other marine purposes. *C. rhomboidea* is the well-known Oyster Bay Pine of eastern Tasmania, but occurs also on the mainland, extending from South Australia to Queensland; its timber is in much demand for telegraph posts. *C. cupressiformis* is the Middle Harbour Pine of Sydney. *C. Muelleri* is the Blue Mountain Cypress.

White Pine.

Calotis, a genus of the family Compositae, consisting of perennial herbs (rarely annuals) endemic in Australia. The involucre is hemispherical; bracts with dry or scarious margins; achenes or ray florets with a pappus of two or more barbed bristles; flowers white, blue, or yellow. *C. cuneifolia* (with blue flowers) and *C. lappulacea* (with yellow flowers) are known in the west as bindieyes (or bindeïs—the spelling is doubtful). Their burr-like flower-heads become entangled by the barbed bristles in the wool of sheep, and thus depreciate the value of the fleece.

Camels. According to N. E. Philipson of Beltana, formerly manager of Sir Thomas Elder's northern stations, the camel was first introduced into Australia in 1840, when the survivor of three animals purchased at Teneriffe was landed at Port Adelaide. The second importation was made in 1860, when Sir H. Barkly, governor of Victoria, was authorized to buy camels from India for the Burke and Wills expedition, and '24 camels from Peshawur, of both the fleet and heavy species, were landed in first-class order.' In 1866 Elder imported 100 camels, of which a large proportion died from a virulent form of mange; the rest were acclimatized on his Beltana station and bred freely—'they thrive' said Philipson, 'on the natural shrubs, especially saltbush and various acacias, and never eat grass unless driven by extreme hunger.' These camels were employed in carrying supplies along the overland telegraph line during

its construction in 1871-3. Camels have been regularly employed for exploration, and have proved eminently suited for carrying heavy goods in the drier regions of the interior. In the Elder scientific expedition (1891-2) David Lindsay's riding camel carried him for 20 days on 6 gallons of water, and extracts from his diary will give details of a camel's endurance: —'1st. August. All except my riding camel had a drink. 24th. Aug. They had their next drink. 30th. Aug. All had their full drink (42 camels—some carrying 700 lb.). 1st. Sep. At 20 miles each had 2½ gallons. 4th. Sep. A few had 2½ gallons. 7th. Sep. The rest had 2½ gallons of dirty water. 25th. Sep. At 400 miles each had 2½ gallons.'

Camels are now in general use in the interior of Western and South Australia, New South Wales, and Queensland, especially in the first two States. They are employed by the survey and the water conservation departments, also as mail-carriers, and for the transport of supplies to mines and telegraph stations. Riding camels are used by the police and by station managers for urgent work, and will cover 100 miles a day for a week. An offender on horseback has no chance against a constable on a dromedary.

Among owners and breeders are still many Afghans, but since the war the industry has begun to pass into the hands of Australians who handled camels in Egypt and Palestine. The South Australian government breeds about 50 a year at Mount Searle On long journeys Arabian camels are loaded with 3 cwt. at most, but much heavier burdens are put on the more strongly-built Egyptian camels. The Australian-bred camel carries an average load of 550 to 600 lb., and will travel 25 miles a day for two months at a stretch.

The latest returns (1922-3) give 11,079 as the number of camels in Australia, but it is believed that there are some hundreds in a wild state in the interior.

Campbell, ROBERT (1769-1846), born at Greenock in Scotland on 28 April 1769, was in 1796 in the employ of his elder brother, the head of Campbell, Clark and Co., merchants in Calcutta. Late in that year the firm sent the *Sydney Cove* with a cargo of merchandise to test the Sydney market; but the vessel encountered heavy gales for nearly two months, leaked seriously, and on 8 February 1797 was beached on Preservation Island in Bass Strait to save her from sinking. (The subsequent adventures of her crew are referred to under EXPLORATION BY SEA.) When the news reached Calcutta, the firm sent off Robert Campbell in the snow *Hunter* to obtain information both about the wreck and about the Sydney market; and his report on the market was so favourable that he was sent back in June 1798 to represent the firm at Sydney. He thus became the first free and non-military merchant to settle in New South Wales. Leasing a strip of land along the western side of Sydney Cove, he constructed what was for many years afterwards well known as 'Campbell's Wharf;' but the grasping policy of the trader-officers of the New South Wales Corps at first prevented him from establishing a regular business. King's arrival, however, in 1800 much improved matters: except spirits, he said (and it was an important exception, for Campbell had just imported 13,336 gallons), anything 'of use or comfort' might be freely imported—'the interest of the fair-dealing merchant, and rescuing the settlers and other inhabitants from the oppressive monopolies that have hitherto existed here, will be equally the object of my attention.' Under the new regime Campbell prospered exceedingly. His importations of cattle from India, under a contract with King, more than doubled the colony's herds between 1800 and 1803; and in the latter year King praised his 'fair and equitable proceedings as a merchant' and welcomed his assistance in destroying 'the extortions and degrading monopolies that formerly existed here.' But he could not resist the tempting trade in spirits, and in 1805 King had to ship back to India 17,500 gallons that had been irregularly imported. This did not, however, hamper his relations with King or his successors, whose official correspondence is full of references to the trade in cattle, sealskins, whale oil, rice, timber, etc., carried on by the Campbell house. Bligh in May 1807 made him treasurer, collector of taxes, and 'naval officer' (i.e. superintendent of customs); this in October brought him into collision with John Macarthur (q.v.) over the importation of distilling apparatus, and (together with his support of Bligh at the time of the mutiny) caused his dismissal from office by Johnston in April 1808, which Foveaux followed up with several bitter attacks on his character and business. Macquarie formally reinstated him, but persuaded him to resign, on the ground that a merchant should not be in a position to levy taxes on his rivals' goods. He gave evidence for Bligh at Johnston's trial in England, and on return to Sydney settled down to enlarge and consolidate his private business. His relations with Macquarie were never very friendly, but Brisbane liked him, and recommended that he should be one of the first non-official members of the legislative council of 1824; Darling appointed him to this position, which he held until the council disappeared in 1843. It is noteworthy that an address presented to Darling in January 1826, in which the appointment of councillors by the crown is criticized, the choice of Campbell to represent local commercial interests is styled good and judicious.

In 1806 King had chartered one of Campbell's vessels, the *Sydney*, to fetch provisions for the colony from Calcutta, and on her way thither she had been wrecked off the New Guinea coast. In 1821, after lengthy negotiations, Bathurst allowed Campbell as compensation for this loss £2000 in cash and another £2000 in land or cattle. In 1825 the allowance was partially satisfied by a grant of 4000 acres at 'Limestone Plains' west of Queanbeyan (see CANBERRA), and in 1829 Darling, by order of the colonial office, increased the grant to 5000 acres. This became the famous Duntroon station, resumed in recent years for the federal military college; to it Campbell retired during the thirties, and began to interest himself in squatting, acquiring about 50,000 acres near Tumberumba. He died at Duntroon on 16 April 1846. After 1810 his chief pursuit was the development of his business. He was trusted and consulted in all important civic affairs, the funds of the first savings bank were deposited with him until 1833, and he was one of the chief supporters of the proposal to establish 'King's schools' under the Church of England which is described under BROUGHTON, W. G. His eldest son Robert, also a merchant, represented the city of Sydney in the legislative

council from 1851 to 1856, and in the new assembly from 1856 to 30 March 1859, when he died. He was treasurer in the first and second Cowper ministries.

Canadian Exiles, a term often applied to a number of political prisoners who in 1839 were transported from Canada to Tasmania. In December 1837 political discontent among the newer settlers in Upper Canada (now the province of Ontario), which had long been governed by a narrow oligarchy controlling its legislative council, culminated in a rebellion intended to transfer the colony to the United States. It was ill-conceived, unpopular, and easily put down; but the British government determined that the rebel leaders must suffer exemplary punishment, and Sir George Arthur, who was at once made lieutenant-governor of the province, had orders to use the utmost rigour of the law against them. About the middle of 1838 17 of them were caught, tried, and sentenced to death; two only, however, were hanged, and the rest transported—some to Bermuda, the rest to Tasmania, which they reached in the *Marquis of Hastings* towards the end of 1839. Three died almost immediately on arrival, owing to the vile conditions that had prevailed in the convict transport; the others were assigned to station owners inland, and three of them (Wait, Gemmel, and Chandler) having in 1841 by direction of the colonial office obtained tickets of leave, used their comparative freedom to escape to New York. The story of their punishment is told in Benjamin Wait's *Letters from Van Dieman's Land* (Buffalo, 1843), coupled with much vindictive abuse of Arthur, who was acting under definite orders in a case of aggravated treason to the Crown: on the outward voyage they, like all the convicts in their company, were disgracefully treated, but in Tasmania they appear to have received fair and considerate treatment. In February 1840 88 more of these rebels reached Australia in the *Buffalo,* 30 being landed at Hobart and the rest taken on to Sydney. There is no record of their later history: they seem to have been absorbed into the mass of convicts without special notice.

Canavalia, a genus of the family Leguminosae, widely distributed and chiefly tropical, consisting of large twiners or trailers. The flowers are large, purplish-pink to white; pod usually oblong, with a prominent longitudinal rib on either side of the upper margin; leaves have 3 leaflets. The only species indigenous to Australia is *C. obtusifolia,* a prostrate, trailing, maritime species, of some value as a sand-binder. The cooked seeds are eaten by the aborigines, but are poisonous when raw.

Canberra, the capital city of the Commonwealth now (1925) under construction, lies in an area which was originally a station on the Molonglo River about 14 miles above its junction with the Murrumbidgee. The district was discovered by Charles Throsby in April 1821, and was traversed by Currie and Ovens in May 1823, during the journey in which they discovered the Monaro Plains (see EXPLORATION BY LAND). In the same year Joshua John Moore, registrar of the governor's court, established a station on the north bank of the Molonglo at a spot which he afterwards referred to sometimes as 'Canberry' and sometimes as 'Canburry.' Almost simultaneously Robert Campbell (q.v.) established his station a few miles upstream at a spot then known as Pialligo. The whole district was in those days called Limestone Plains. As was then usual, the land was first occupied, then asked for: permission to occupy would then be given, either by warrant or verbally by the governor, and the formal deed of grant issued several years later. Moore occupied his land in 1823, obtained his warrant on 3 May 1825, and his grant on 12 October 1838: Campbell occupied his in or about 1823, obtained a promise from Brisbane on 18 May 1825, and his grant on 29 October 1834. Moore's grant—which he purchased for £250—was of 1000 acres, subsequently increased by a further purchase (at the same rate) to 1742 acres: it is variously described by the surveyors as 'Canbury,' 'Canberry,' and 'Cambury.' The Polish naturalist Lhotsky, who visited the district in 1834, spells it 'Kembery,' and says that this was the name given by the local aborigines to that part of the Molonglo River, but Moore talks of 'Canburry Creek' as a tributary of the Molonglo. Sir Thomas Mitchell, then surveyor-general and all-powerful in the matter of nomenclature, approved of the name: and, as he had a strong and frequently expressed objection to the foisting of English names on Australian localities, we may regard it as certain that 'Canberra,' however it is spelt, is of aboriginal origin. The spelling just given, which is now official, is first found in official documents about 1857. The official pronunciation was definitely settled on 12 March 1913, when Lady Denman (wife of the then governor-general) in announcing the name of the future capital city stated definitely that it must be spelt with two 'r's, but pronounced with the accent on the first syllable (i.e. as though it were 'Cannbera').

The name Canbury was originally applied only to Moore's grant, but was soon extended to include the whole plain north of the Molonglo between Black Mountain and Mount Ainslie, Moore's grant thenceforward being known as Acton. In 1841-5 the Campbell family built in the middle of the plain a church which took its name; a few houses sprang up round the church, and by the end of the fifties had constituted the village of Canberra.

The story of Campbell's grant is told under his name. It was originally of 4000 acres, another 1000 acres being granted to him by Darling in 1830; this became the nucleus of Duntroon station, which is now the site of the Royal Military College of Australia.

Up to 1908 the Molonglo valley from Queanbeyan downwards was merely one among many tableland areas near the main range occupied by squatters. In the thirties and forties there was a small amount of closer settlement, free immigrants with their families taking up their residence round Queanbeyan but acting either as tenant farmers or as station employees. In the sixties a good many of these men became small freeholders, acquiring their farms as selections under the Robertson land acts; but up to 1911 the best part of the area that now constitutes the Federal Territory was comprised in nine large stations. Gungahlin (20,000 acres), Duntroon (30,000), Yarralumla (40,000), and Uriarra (20,000) lay side by side in the north; southwards were Tidbinbilla (10,000), Tuggeranong (11,000), Lanyon (10,000), Cuppacumbalong (18,000) and Booroomba (28,000), besides a large area of leased cattle-country in the Gudgenby watershed. On a small farm, Lambrigg near Cuppacumbalong, W. J. Farrer (q.v.) carried out many of his experiments in wheat-growing.

It was the debates over the site of the federal

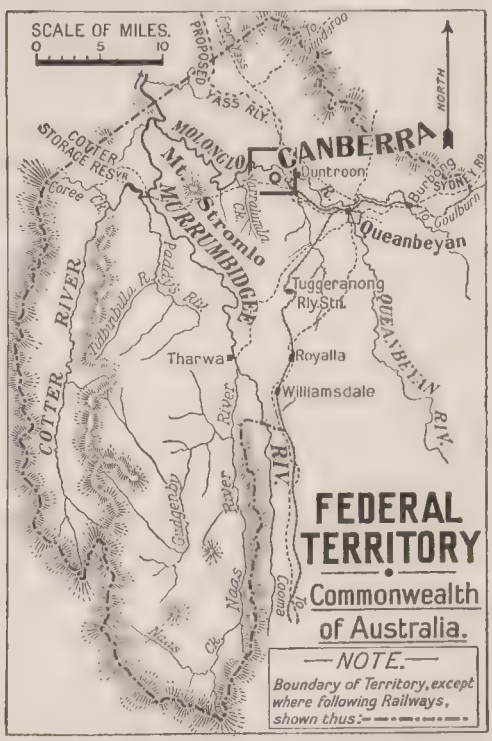
capital city, of which an account follows, that at last brought the district into prominence. Section 125 of the constitution provides that

> The seat of Government of the Commonwealth shall be determined by the Parliament, and shall be within territory which shall have been granted to or acquired by the Commonwealth, and shall be vested in and belong to the Commonwealth, and shall be in the State of New South Wales, and be distant not less than one hundred miles from Sydney.
>
> Such territory shall contain an area of not less than one hundred square miles, and such portion thereof as shall consist of Crown lands shall be granted to the Commonwealth without any payment therefor.

This clause was placed in the constitution as a result of the premiers' conference of 1899, and in November of that year the New South Wales government appointed a commission which reported that the most suitable districts were (*a*) the southern Monaro, round Bombala or Eden, (*b*) the Canobolas hills near Orange, (*c*) Yass. In January 1903 the Federal government appointed a royal commission to report on sites near Albury, Armidale, Bombala, Lake George, Orange (including the district from Bathurst to Lyndhurst), and Tumut. The report, issued in July, placed these sites in the following order, Albury, Tumut, Orange, Lyndhurst, Armidale and Bathurst (equal), Lake George, Bombala, and Dalgety (equal); but a supplementary report dated 4 August gave special consideration to the site of Dalgety.

In October, a ballot having been taken to ascertain the opinions of members, Tumut was selected, and a bill to confirm this choice was passed by the house of representatives; the senate, however, substituted Bombala. The federal government then obtained from the government of New South Wales the services of two surveyors to investigate the rival districts, and after considering their report passed on 15 August 1904 a seat of government act establishing the capital site within 17 miles of Dalgety on the Snowy River, NW. of Bombala, and providing that the territory should contain an area of not less than 900 square miles, and should have access to the sea. This decision aroused violent opposition in the New South Wales legislature, as the locality was considered too far from Sydney, and on 23 December Joseph Carruthers, then premier, forwarded to the prime minister (George Reid, a New South Wales representative) resolutions passed by both houses of the State parliament to the effect that (*a*) New South Wales would not grant 900 square miles in any part of the State, (*b*) the true intent of section 125 of the constitution act, as understood by the State, was that the area should be a hundred square miles, (*c*) the government was authorized to offer between 100 and 200 square miles at or near Tumut, Lyndhurst, or Yass, (*d*) the State was prepared to make provision outside such areas for the water-supply of the new capital, (*e*) the matter of railway construction should be carefully arranged, as the State was not prepared to enter into any large expenditure. This peremptory attitude of the State most concerned brought about a deadlock. Tumut had already been deliberately set aside; Lyndhurst was too deeply imbedded in New South Wales territory, too far from the sea, and too awkwardly situated as regards railway approach, to stand a chance of acceptance; Yass had been in the field from the first, and had won no favour at any time. Besides Dalgety was definitely settled on, and the refusal of the New South Wales legislature to consider it seemed to many federal members a form of insolence. Eminent lawyers were agreed that section 125 gave the Commonwealth power to take such territory as it required even against the wishes of the State. But friction was undesirable: in 1905-8 Alfred Deakin was prime minister, and he shrank from any drastic procedure; and the whole matter was put aside for some years.

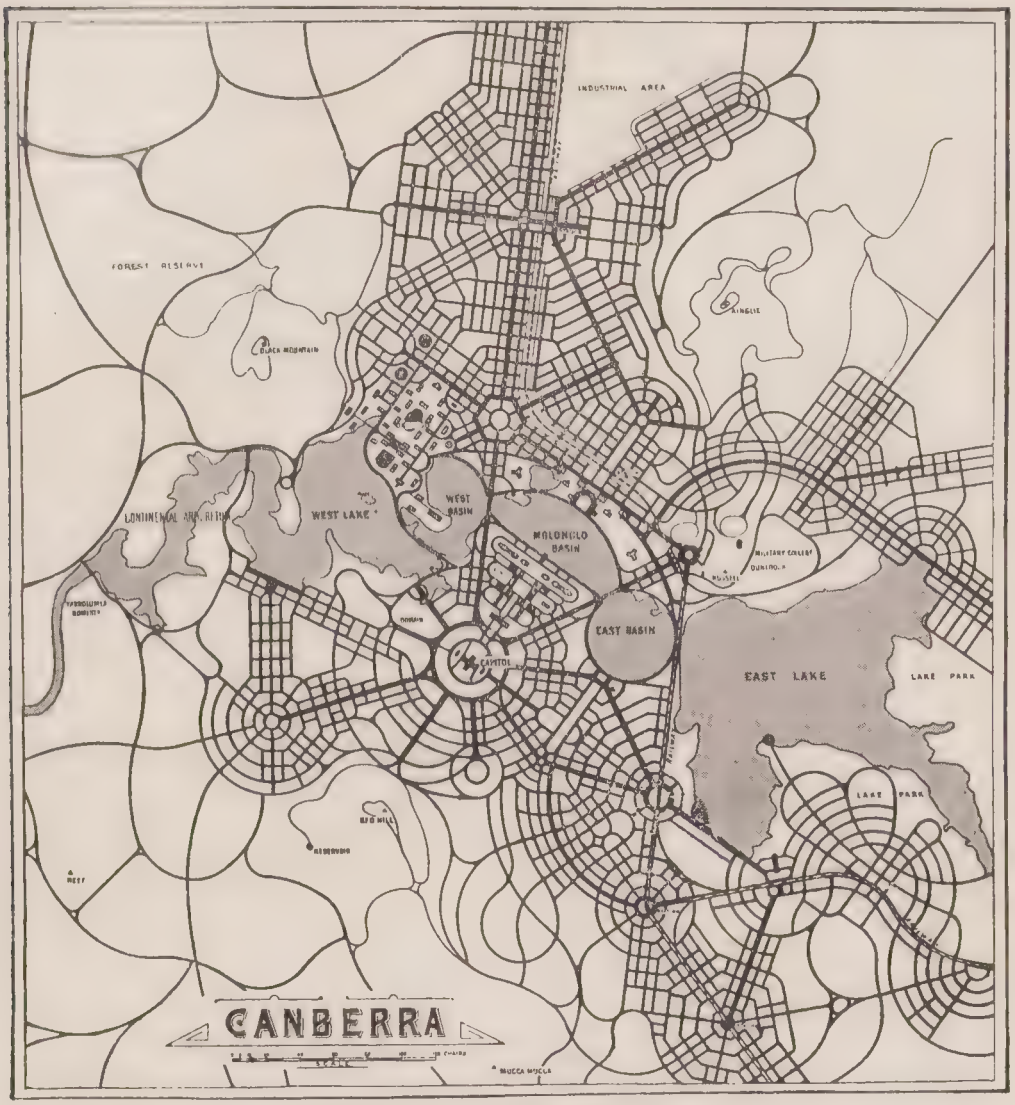
Up to 1907 the Canberra district had not been thought of in this connection, but in that year several New South Wales members of the federal parliament (including J. C. Watson, the leader of the Labour party) passed through it on an angling holiday, and were struck with its suitability for the display of fine architecture and town-planning. When the parliament met in 1908, the question of the capital site was again considered, and to give members an opportunity of finally settling it, a bill 'to determine more definitely the seat of government in the neighbourhood of Dalgety' was introduced on 22 September. Even then it was found impossible to unite all the opponents of Dalgety in favour of any other single site: so the device was adopted of amalgamating for the purpose of the debate two neighbouring but quite distinct sites, and the bill was amended by the substitution of 'Yass-Canberra' for 'Dalgety,' leaving



the choice between the two districts thus joined up for later consideration. The act, which was assented to on 14 December, provided (*a*) that the seat of government should be in the district of Yass-Canberra, (*b*) that the territory to be acquired by the Commonwealth should contain an area of not less than 900 square miles, and (*c*) that the territory should have access to the sea.

Early in 1909, therefore, the Yass-Canberra region was surveyed, and the actual Canberra area found to be the most suitable location for a city worthy to become the capital of Aus-

tralia. It was further recommended that the territory attached to it should include the valley of the Cotter River, an uninhabited catchment fit to provide water for the city, and the valleys of the Molonglo and Queanbeyan Rivers, whose united waters flow through the city area. In March an advisory board (whose conclusions were adopted by the federal government) suggested the acquisition of about 1015 square miles of territory as just described, together with about 2300 acres at Jervis Bay to be made into a federal port. Subsequent negotiations resulted in alterations that excluded the upper Molonglo and Queanbeyan from the new territory, and included a long strip of partially settled country along the Murrumbidgee; acts ratifying the latest agreement were passed by the federal and State parliaments, and on 1 January 1910 an area of about 900 square miles round and south of Canberra, and another of about 4000 acres at Jervis Bay, were constituted the Federal Capital Territory. Of the Canberra territory—583,660 acres in all—about 200,000 acres were then or subsequently acquired



Official Plan of the Capital City.

from their former owners at a cost of about £725,000: this area comprised most of the land lying north and east of the Murrumbidgee, including Acton, Duntroon, Yarralumla, Gungahlin, Tidbinbilla, Tuggeranong, and part of Uriarra, as well as several smaller holdings.

Out of the total area of the Territory about 12 square miles (7680 acres) were set apart for the city site, and about 100,000 acres more reserved for parks, roads, military college, and other public purposes outside the city area. In 1911 the Commonwealth invited designs for the lay-out of the federal city; a board appointed to consider them furnished a majority and a minority report, and another board after consideration of the various designs incorporated features from several of them in a design of its own, which was adopted. The designs most approved of were made by architects from Chicago, Helsingfors, and Paris, and the greater

part of the final design was due to the Chicago planner, Walter Burley Griffin. On 12 March 1913 building operations were officially initiated, the foundation stones of a 'Commencement Column' being laid by the governor-general (Lord Denman), the prime minister (Andrew Fisher), and the minister for home affairs. The military college had already been opened at Duntroon in June 1911, and a naval college—which was in existence, temporarily housed near Geelong in Victoria—established on federal territory at Jervis Bay in 1914. Since then several foundation stones have been laid—notably that of the capitol by the Prince of Wales in 1920. Actual building operations have been much delayed. In 1913-4 a general survey of the site was completed, and certain areas were allotted for early development; the water-supply was also provided for by damming the Cotter River. The war at first hindered and from 1916 onwards put a stop to all activity at Canberra, but in 1921 a committee of five experts in engineering and architecture was appointed to devise a scheme for progressive construction of the city. A great deal of preliminary work has been completed, water mains, sewers, and electric light and power have been installed, and belts of trees have been planted to mark the city avenues and parks. The construction of the great permanent buildings is being delayed until the Commonwealth can afford to spend a good deal of money on them, but provisional buildings are being erected (1924) to accommodate the parliament, the principal departments, and such residents and visitors as a meeting of parliament must attract.

Canberra city lies about 2000 feet above sea-level in 35° 15′ S. lat. and 149° 15′ E. long. It is about 75 miles in a direct line from the coast, 204 miles by rail from Sydney, 429 from Melbourne, 912 from Adelaide, 929 from Brisbane, and 2599 from Perth. Access to the sea will be obtained by a railway 123 miles long, ending in the federal area at Jervis Bay. The average annual rainfall at Canberra is 22.63 inches, the mean summer temperature 67.5° Fahr., and the mean winter temperature 41.8°; it is thus slightly warmer than Melbourne in summer, and cooler than any State capital in winter. Being situated on a tableland instead of on the coast, its four climatic seasons are sharply differentiated, its summer heat is dry, and its winter cold, frosty, and invigorating. The Federal territory extends to within 60 miles of Mount Kosciusko, and includes a cluster of peaks over 5000 feet high.

Statistics.—*Area*: 940 square miles. *Population* (1924), 3677 whites. *Stock* (1922-3): cattle, 6275; sheep, 139,063. *Chief Products* (1922-3): wheat, 7176 bushels; milk, 106,075 gallons; butter, 18,248 lb.

See W. D. Wright's *Canberra*, F. W. Robinson's *Canberra's First Hundred Years*, and the *Official Year Books of the Commonwealth* for 1910 and 1911 (Nos. 4 and 5).

Candle-nut Tree. See ALEURITES.

Candollcaceae, a small indigenous family of herbs or undershrubs, found chiefly in Western Australia. They have a calyx-limb of 5 divisions, free or more or less united in two lips (upper lip 3-lobed, lower 2-lobed); corolla irregular, with 5 lobes, one much smaller than the others; stamens 2, attached to the style and forming a column; capsule opening downwards in 2 valves; leaves usually basal, tufted or rosetted. In the genus *Candollea* (Trigger Plants) the column is curved, elastic and extremely sensitive, a valuable adaptation for securing pollination. When touched by a visiting insect, the column springs sharply back and

Candollea serrulata.

straightens out, flinging the pollen on the back of the intruder, who carries it to the next flower visited and rubs it off on the stigma.

Canterbury, VISCOUNT (1814-1877), John Henry Thomas Manners-Sutton, third Viscount Canterbury, born in London on 27 May 1814 and educated at Eton and Trinity College, Cambridge (M.A., 1835), studied for the bar, but abandoned that profession for politics and in September 1839 was returned to parliament by the borough of Cambridge. Unseated on petition, he was again returned in 1841, and sat for the borough up to 1847; from September 1841 to July 1846 he was under-secretary for the home department in Sir R. Peel's ministry. On 1 July 1854 he was appointed lieutenant-governor of New Brunswick, and held that post to October 1861; on 24 June 1864 he became governor of Trinidad, and on 19 May 1866 succeeded Sir Charles Darling (q.v.) as governor of Victoria. His governorship is chiefly notable for his solution of the 'Darling deadlock;' he was less complaisant to the McCulloch ministry than his predecessor had been, and refused to endorse supreme court judgments in favour of government creditors. In May 1868, therefore, McCulloch resigned, and the Sladen ministry attempted to carry on the government in the face of a vote of want of confidence. During the ensuing political warfare Manners-Sutton loyally adhered to his instructions from the home government, but did not disguise the fact that his sympathies were with the minority ministry. In July the McCulloch party resumed office after an appeal to the country. In November 1869 Manners-Sutton succeeded his elder brother as third Viscount Canterbury. In March 1873 he resigned the governorship, in which he had attained great popularity, and returned to

England where he spoke a few times on colonial questions in the house of lords, and died on 24 June 1877. (K.C.B., 1866; G.C.M.G., 1873.)

Canthium, a large genus of the family Rubiaceae, consisting of shrubs often arborescent, and chiefly tropical. The flowers are in clusters; calyx toothed, corolla-tube short, 4-lobed; fruit a compressed, globular drupe with one or two stone-like seeds; branches sometimes thorny. The following species are suitable for turnery and cabinet work: *C. buxifolium,* wood light-coloured; *C. coprosmoides,* wood dark yellow, streaked with brown; *C. latifolium,* a close-grained, highly ornamental timber, pinkish with darker streaks; *C. lucidum,* a tough and nicely-marked yellow wood. The wood of *C. olcifolium* is capable of a high polish.

Cape, William (1773-1847), born at Ireby in Cumberland, was for many years manager of a leading London bank, and, finding it difficult to maintain his family in England after the bank went into liquidation, decided in 1821 to migrate to Australia. This decision was mainly due to the advice of Thomas Hobbes Scott (q.v.), just returned from Sydney, where he had been acting as secretary to J. T. Bigge; and Scott's influence, together with that of his brother-in-law Lord Oxford, who had been a customer of the bank, assured Cape a welcome in Sydney and the usual grants of land. In January 1822 he with his wife and seven children sailed for Hobart, where he intended to settle, and reached it on 27 May; almost immediately, however, he sailed with his eldest son for Sydney to prosecute a case against the master of a vessel with whom his passage had been booked, but had been cancelled through the master's default. Having won his case and presented his introductions, he was advised by Governor Brisbane to postpone the selection of his land-grants and accept the headmastership of a public school about to be established in Castlereagh-street. Bringing over his family from Hobart, he took over in February 1823 the Sydney Academy (see Schools) from the executors of its founder Isaac Wood; in April 1824 he took the headmastership which Brisbane had offered, and introduced into the new school Pestalozzi's methods of primary education. The work was carried on successfully for two years in the upper rooms of the old court-house (afterwards a girls' high school, and since demolished); but in 1826 Archdeacon Scott, according to Cape, 'reduced this most flourishing establishment to a mere Parochial School of St. James,' and Cape handed the school over to his son William Timothy Cape (q.v.), and applied for his land-grants. Brisbane gave him 2000 acres, and his two elder sons 500 acres each; complications arose, Darling and his secretary Macleay were less friendly than Brisbane and his secretary Goulburn had been, and for another 20 years Cape lived, a man with a grievance, on his farm at Wyong Creek. From 1826 to 1840 he published weekly weather tables in the *Monitor* (and from 1832 to 1838 in the *Herald*) which, filling as they did a gap when there were no official weather records, have been valuable to later meteorologists. He died at Sydney on 19 November 1847. One of his daughters adopted her father's profession, and kept a girls' school in O'Connell-street during the thirties.

Cape, William Timothy (1806-1863), eldest son of William Cape mentioned above, was born at Walworth in Surrey on 25 October 1806 and educated at Merchant Taylors' school, London. He accompanied his father to Tasmania early in 1822 and to Sydney in June of that year, and assisted him at both the Sydney academy and the Sydney public school. When the elder Cape resigned his headmastership in 1826, W. T. Cape succeeded him as headmaster and retained the post till he also resigned in July 1829. At the end of that year he opened a private school at the corner of King- and Phillip-streets, and for the next five years was engaged in training most of the colony's promising youth; but at the end of 1834 he was persuaded by the trustees of the Sydney college (since known as the Sydney Grammar School —see Schools) to take the headmastership of their new institution. With 60 of his pupils he migrated to the new building on College-street, and in seven years built up the reputation of the grammar school. In 1841, however, he quarrelled with the trustees for spending their money on buildings instead of providing adequate salaries for the staff, refused to renew his engagement as headmaster, and next year opened a school of his own in Glenmore-road, Paddington; this he carried on until 1856, when he retired from educational work and in 1859 was elected by Wollombi (the constituency in which his father's farm lay) to the legislative assembly, becoming about the same time a commissioner of national education and a fellow of St. Paul's College within the university of Sydney. In 1860 he found these appointments uncongenial, resigned them all, and returned to England to complete the education of his children. There he died of smallpox on 14 June 1863.

Cape was a great teacher, not so much because of his learning—which was adequate but not profound—as because of his personality and his entire devotion to the character-building side of his work. His aim was to provide the community with great citizens, whether as judges, legislators or unofficial leaders of society, and his training was so devised as to fit his pupils for exerting the influence he prognosticated for them. Among them were James Martin, William Forster, James Dowling, John Robertson, and Thomas Browne whom we know as Rolf Boldrewood, besides several Mitchells and Stephens and Broughtons. Nor was he content with influencing schoolboys; he was the founder of the Sydney Mechanics' School of Arts, and throughout his association with it endeavoured to make it a training-school for the members.

Capparidaceae, a widespread family of herbs and shrubs (more rarely trees), widely distributed in warm to tropical regions. Six genera with 35 species are indigenous to Australia. The genus *Cleome* has 4 indigenous species. *C. viscosa,* an erect herb with an elongated capsule and yellow flowers with 4 petals, bears a strong resemblance to a cruciferous plant. It ranges from Western Australia to northern Australia, and extends to India. It is used by the aborigines to relieve headaches. In the United States the roots are used as a vermifuge. In India the leaves, boiled in ghee,

are applied to recent wounds. *Apophyllum anomalum,* an almost leafless tree with small fragrant flowers, is an interior species with a hard timber. See CAPPARIS.

Capparis, a genus of the family Capparidaceae, consisting of trees or shrubs distributed over tropical regions, 20 species being indigenous to Australia. *C. Nobilis,* the Mock Orange, is a small tree armed with conical prickles, which ranges coastally from New South Wales to Queensland. It has a hard, light-coloured wood. *C. Mitchelli* (Native Pomegranate), the 'monda' of the central Queensland blacks, is an inland species extending from South Australia to northern Australia. Both species have showy flowers and large succulent fruits; those of *C. Mitchelli,* which have an agreeable perfume, are eaten by the aborigines.

Carandini, MARIE (1826-1894), born at Brixton, near London in 1826, was the daughter of James Burgess and, through her mother, connected with Shelley and with Byron's friend Medwin. In 1833 the Burgess family migrated to Tasmania, where the father died, and Marie in 1843 became the wife of Count Carandini, an Italian political refugee and teacher of dancing. In January 1845 Carandini took his wife to Sydney to receive better musical training than was obtainable then in Hobart; he himself opened a dancing school and frequently appeared on the stage, and Marie began her stage career as Lady Allcash in *Fra Diavolo* on 5 August 1845. For the next nine years she was a favourite on the Sydney stage, usually appearing in light opera, and at the same time studying assiduously under Isaac Nathan (q.v.) and Sara Flower; and when Catherine Hayes, the Irish *prima donna,* visited Sydney, she chose Marie to interpret many of the contralto roles in her operas—e.g. Elvino in *La Sonnambula* and Gennaro in *Lucrezia Borgia.* With Catherine Hayes Marie went to Melbourne, and soon became herself a *prima donna,* singing Leonora (*Il Trovatore*) at the Princess Theatre with great success. In 1859, being invited to Sydney to sing at the opening of the great hall of the university, she took the opportunity to produce *Il Trovatore* at the Prince of Wales Theatre—its first performance in Sydney. In later years she took a concert company which included Sara Flower and Walter Sherwin through Australia and Tasmania, also visiting New Zealand, India and the United States. In 1870 Count Carandini was pardoned by the Italian government and returned to Italy, but died at Modena shortly after his arrival there. Madame Carandini died in 1894. Her daughter, ROSINA MARTHA HOZANAH CARANDINI, born at Hobart on 28 August 1844 and married in 1860 to Edward H. Palmer, was for many years a favourite concert singer and teacher of singing in Melbourne.

Carissa, a mainly tropical genus of the family Apocynaceae, with two species endemic in eastern Australia. *C. Brownii* (Native Scrub Lime) is a much-branched shrub, armed with horizontally simple (occasionally forked) spines, which ranges from the northern rivers of New South Wales up to northern Australia. It has a pleasant, wholesome fruit like a sloe, about half an inch long, containing a milky juice. It is known to aborigines of the Rockhampton district as 'karey.' The wood is hard and clear, and works well. Along the grain there are a number of white, pithy streaks which give it a pretty, dotted appearance.

Carmichael, BARON. Sir Thomas David Gibson Carmichael, first Baron Carmichael of Skirling, son of the 13th baronet, was born in Edinburgh on 18 March 1859, educated at Cambridge (B.A., 1881; M.A., 1884), entered politics as private secretary to Sir G. Trevelyan and Lord Dalhousie, and in 1895 succeeded W. E. Gladstone as member for Midlothian, but left politics in 1900. In 1904 he became a trustee of the national portrait gallery in London, and in 1906 of the national gallery, but resigned both positions on being appointed in 1908 governor of Victoria. Here his term of office was distinguished by the great encouragement he gave to literature and art. In 1911 he was transferred from the colonial to the India office and made governor of Madras, in preparation for the further move —which took place in the following year—to Bengal. It had been decided to cancel Lord Curzon's division of the Bengal province and to reunite it (with the loss of Bihar and Orissa), while removing the capital of India to Delhi; such drastic changes affecting a disturbed province needed great tact in administration, and Lord Carmichael was specially chosen for the task. He governed Bengal until 1917, and has since resided in Great Britain. (K.C.M.G., 1908; G.C.I.E., 1911; G.C.S.I., 1917. Created a baron, 1912.)

Carpet Shark. See WOBBEGONG.

Carpet Snakes. See SNAKES.

Carr, THOMAS JOSEPH (1839-1917), born in Galway in 1839 and educated at Tuam and Maynooth, was ordained priest in 1866, and in 1870 returned to Tuam as professor of rhetoric. Two years later he was appointed dean at Maynooth, becoming professor of theology in 1874, and vice-president of the college in 1880; in the same year he was made editor of the *Irish Ecclesiastical Record,* the official organ of the Catholic Church in Ireland. On 26 August 1883 he was consecrated bishop of Galway. At the request of the Australian bishops he was in September 1886 translated to the see of Melbourne in succession to Archbishop Goold, was invested with the pallium at Rome, and reached Melbourne on 11 June 1887. During his long administration the archdiocese prospered greatly; the number of its priests grew from 55 to nearly 200, many new parishes were formed, new orders of men and women were introduced (necessitating the building of numerous convents, churches, and chapels), and the noble edifice of St. Patrick's Cathedral in Melbourne was completed. His last great work, unfinished at his death, was the foundation and erection of Newman College within the university of Melbourne. In September 1911, when he celebrated his silver jubilee as archbishop, he was made an assistant to the pontifical throne. He died in Melbourne on 6 May 1917.

Archbishop Carr was noted not only as an administrator but as a controversialist; and among his many writings—which include five large volumes and numerous pamphlets—his work on *The Blessed Eucharist* is favourably known in Europe as embodying much original research. His *Primacy of the Roman Pontiff* is also noteworthy. He was a man of gentle demeanour, easily accessible, and much loved by his people. E.M.O'B.

Cartwright, ROBERT (1771-1856), born in England in 1771 and educated at St. Edmund's Hall, Oxford, in 1794 took holy orders and was curate of Bradford in Yorkshire for 14 years. Samuel Marsden (q.v.), during a visit to Yorkshire in 1808, persuaded Cartwright to accompany him back to New South Wales, and obtained his formal appointment as colonial chaplain. Reaching Sydney on 27 February 1810, Cartwright was at once sent to work in the Hawkesbury district, and in June 1811 was made a magistrate for the district. By 1817 the strain of managing such a huge parish was breaking down his health (it is amusing to note that Marsden, who mentions this, five days later suggested that Cartwright should take on his (Marsden's) work also during his projected visit to England) and in December 1819 he was at his own request transferred to Liverpool. Macquarie valued and liked him, and on more than one occasion took him along as a sort of domestic chaplain on tours of inspection: and Cartwright seized the chance of advocating in his sermons then preached 'the justice, good policy, and expediency of civilizing the aborigines . . . . and settling them in townships.' This project he conceived in 1819, put it before Macquarie in a letter accompanied by 'a kind of verse' which has unfortunately been lost, and followed up this by submitting on 18 January 1820 an elaborate plan for a reservation at the Cowpastures, between the Nepean and the Warragamba, with a township near the main road and separate areas allotted to the several tribes. The plan was never carried out, Macquarie preferring (probably to save expense) to establish three small reservations at Elizabeth Bay, George's Head, and Blacktown.

The value of Cartwright's services was in 1824 recognized by the colonial office both in set terms and by the grant of compensations and additional allowances, and in 1825 he undertook also (possibly to improve his still precarious financial position) the headmastership of the male orphan school, which was 'in the most deplorable state of irregularity, disease, and vice.' It took him four years, Archdeacon Scott records, to establish 'a system of unprecedented order and propriety;' and it is hardly to be wondered at that in 1826 he refused to add to his burdens the headmastership of the female orphan school. In 1829 Scott appealed to the governor for the promise of an annuity to Cartwright's widow in case of his death: but under the Whig governments of the thirties the colonial office grew unsympathetic and over-economical, and grudged all concessions to officials.

In 1836 Cartwright resigned the Liverpool cure, and for two years was in charge of St. James's, Sydney. In 1838 he retired from parochial work and settled near Collector, south of Goulburn, where for many years he acted as honorary itinerant preacher for the area to south and west. In 1851 he is described as bishop's commissary. He died at Collector on 14 December 1856.

Carvosso, BENJAMIN (1789-1854), son of William Carvosso the evangelist, was born at Gluvais in Cornwall in 1789, entered the ministry in 1814 and arrived in Sydney in 1820. After spending five years in Windsor, Parramatta, and Sydney he was transferred to Hobart, where he had preached on his way out, being the first Wesleyan missionary to conduct worship in the island. While in Sydney he, in conjunction with Walter Lawry and Ralph Mansfield, edited the *Australian Magazine* and helped to establish a floating chapel for seamen, the first service being held in the brig *Lynx* in November 1822. In 1830 he returned to England and died in Cornwall in 1854.

See Blencowe's *Faithful Pastor* (1859).

J.C.

Cash, MARTIN (1809-1877), born at Enniscorthy in county Wexford, Ireland, was transported to Australia in 1827 for an attempt to murder a rival in a love affair. Reaching Sydney in the *Marquis of Huntly* on 30 January 1828, he was assigned to James Bowman, and by him sent to work on Wybong station in the hills west of Scone (Hunter River valley), where he in due course gained a ticket of leave and then freedom. In 1837 he was detected in branding stolen cattle (innocently, by his own account), and thought it wiser to leave the district: via Mudgee and Bathurst he reached the Goulburn district, and obtained work as a dairyman on Captain Sturt's farm near Mittagong (which he calls 'Meadow Gang'), but quarrelled with an overseer and made his way via Sydney to Tasmania, reaching Hobart on 12 February 1837. Settling at Campbelltown, he soon became notorious as a hot-tempered man who took offence on small provocation and frequently came into collision with the police: in March 1840 he was sentenced to seven years' penal servitude and sent to a penal station near Richmond. At once he escaped: re-captured, he escaped again, and for a year worked in the Huon district (where he was not known) in order to obtain money for a passage to Melbourne. Coming to Hobart to secure this passage, he was recognized, caught, and given four years at Port Arthur for absconding. From this prison he escaped by swimming Eaglehawk Bay, which was supposed to be full of sharks (this, however, was merely a tale invented to frighten absconding convicts): but he was caught again near East Bay Neck, and sentenced to 18 months' labour in the stone-quarry.

Up to this time, apparently, Cash had not contemplated a bushranger's career. But in the quarries he met Kavanagh and Jones, two convicts who had been sent to Port Arthur for bushranging near Sydney, and the three combined to utilize his talent for absconding and theirs for making a living afterwards. They swam the narrow inlet, crawled at midnight past a sentry-box on East Bay Neck, and established themselves in a camp on the Dromedary (north of New Norfolk) from which they raided settlers on the Derwent and its tributaries. From Ross on the upper Macquarie to Lake Echo, and south to the Derwent, no one was safe from their visits, and detachments of soldiers hunted them in vain. In 1843 Kavanagh was wounded, and gave himself up: and on 29 August in that year Cash was caught while on a visit to Hobart, tried on 15 September for the murder of a constable who had been shot in the scuffle, sentenced to death, and reprieved (after 15 months of suspense) to Norfolk Island for life. Kavanagh, tried at the same time for an earlier act of bushranging, received the same sentence and reprieve. On the island, however, Kavanagh within a year joined in a mutiny and was hanged. Cash, by a course of steady good conduct that earned him the favour

of the martinet John Price (q.v.), obtained regular promotion and a pardon, returned to Tasmania when the penal settlement was broken up in 1853, was for a time caretaker at the Hobart botanical garden, put in four years in New Zealand, and finally settled down at Glenorchy near Hobart to write his memoirs and die in the odour of respectability on 27 August 1877.

Our main source of information about Cash is his autobiography published in Hobart in 1870. The dates in this, where they can be checked, are frequently inaccurate, as might be expected, but there is no reason to doubt the general truth of Cash's statements, though he certainly exaggerated some of his sufferings as a convict—e.g. his treatment by John Price at Norfolk Island.

Cassia, a large genus of the family Leguminosae, sub-family Caesalpineae, consisting of trees, shrubs, or herbs, tropical or subtropical, particularly abundant in America. The flowers are yellow, rarely white or reddish; leaves divided into more or less numerous leaflets; pod flat or cylindrical. Many species are cultivated as ornamental shrubs. *C. absus* has bitter aromatic seeds, a preparation of which is used in Egypt for ophthalmia. The pods and leaves of *C. eremophila* are eaten by stock. *C. Brewsteri* (Queensland Laburnum) has a pale yellow wood, close-grained and nicely marked. The senna of commerce is obtained from several species, mainly from two growing in Egypt and India respectively; and von Mueller thought that the leaves of *C. artemisioides,* an inland Australian species, might be found effective in a similar way. Cassia bark, it should be noted, is not connected with this genus, being a product of *Cinnamomum cassia.*

Cassinia, a genus of the family Compositae, consisting of ornamental shrubs with white or yellowish shining bracts. It is represented by several species in New Zealand, and by one in South Africa, but all the Australian species are endemic. The involucre is oblong, bracts scarious or coloured; seeds short, angular or cylindrical, usually papillose with a pappus of entire or minutely denticulate bristles in a single row, cohering only at the base. *C. aurea* has a graceful habit, and produces a profusion of pale golden flowers. *C. laevis* has a dark, close-grained wood, while that of *C. aculeata* is white.

Cassowary, a genus (*Casuarius*) of large flightless birds, constituting the family Casuariidae, found in the tropical scrubs of northern Queensland and in New Guinea, the Aru Islands and Ceram. The Queensland species (*C. casuarius*) is characterized by its large bony helmet or casque, and by the pendent red wattles on the front of its neck. The head and neck are otherwise practically naked, the skin being bright blue with an orange patch at the back of the neck. The body is clothed with black, hair-like feathers, double as in the emu (q.v.), and the wings bear some large hollow black spines. The cassowary lays 3 to 6 pale green, granulated eggs, usually somewhat larger than those of the emu, in a nest built up of sticks and leaves on the ground in the scrub, often at the foot of a tree. The breeding-season is from July to September, incubation occupying about two months. The young birds are yellowish-brown, with longitudinal black stripes.

Cassowaries are shy birds, feeding on jungle fruits; the bony casque, which is directed forward, protects the bird's head as it makes its way through the thick undergrowth in which its food is found.

The name is of Malay origin, the bird having been known in the Moluccas from a remote period. In New Guinea and the adjacent islands

Cassowary.

there are numerous species and races, differing among themselves chiefly in the coloration of the neck and the form of the helmet and wattles; it is possible that more than one race is to be found in Queensland.

The first cassowary seen in Australia by white men was shot by the aboriginal Jackey near Princess Charlotte Bay on 4 November 1848, during Kennedy's ill-fated expedition to the Cape York Peninsula, and its skin was brought to Weymouth Bay by Thomas Wall, the naturalist attached to the expedition. According to Carron, one of the survivors, two more birds were seen during the journey. The first living specimen, however, was not captured until 16 March 1871. See EMU.

W.B.A.

Cassytha, a genus of the family Lauraceae, chiefly Australian and largely maritime, consisting of leafless parasites with wiry stems, which attach themselves to living plants by means of small suckers (haustoria). The small flowers are arranged in clusters, and the seeds are enclosed in the enlarged succulent calyx-tube; leaves replaced by minute scales. There are 12 indigenous species, about equally divided between east and west, one species, *C. glabella* (Devil's Twine), being found in all the States. *C. filiformis* (Dodder Laurel), which extends from Queensland to northern Australia, has a wide tropical range. It is used in India by the Brahmins for seasoning buttermilk. Crushed with gingelly oil, it is used as a wash for strengthening the hair.

Castanospermum, a genus of the family Leguminosae, consisting of one species, which is endemic in Australia—*C. australe* (the Moreton Bay Chestnut, Bean-tree or Black-bean), a tall tree which reaches its southern limit on the northern rivers of New South Wales. The leaves are 1-1½ feet long with from 11 to 15 leaflets; flowers large, orange-red, in loose clusters; pod large, swollen, almost woody, spongy inside; seeds large, globular. The beans are used as a food by the aborigines, who prepare them by first steeping them in water from 8 to 10 days. They are then

taken out, dried in the sun, roasted upon hot stones and pounded into a coarse meal; the meal may be kept for an indefinite period. When required for use the meal is mixed with water, made into a thin cake, and baked in the usual manner; the cakes taste like a coarse ship's biscuit. A sample of starch made from these beans was exhibited at the Melbourne Exhibition in 1866. They are suspected of poisoning stock,

Moreton Bay Chestnut.

but no poisonous property has been isolated; it is suggested that any injury suffered by stock from eating them has been due to their indigestibility. The timber is soft, fine-grained, and takes a good polish, but is not durable. Somewhat like walnut, it is used for cabinet work. The tree is a common feature in our parks and gardens.

Castor Oil Plant. See NOXIOUS PLANTS.

Casuarinaceae, a family of self-pollinated trees or shrubs with uni-sexual flowers, the males in elongated cylindrical spikes that terminate the branchlets, the females axillary in dense ovoid or globular heads, sessile or shortly stalked. The fruit is an ovoid or cylindrical cone; seed a laterally compressed nut, smooth and shining, produced at the apex into a membranous wing which assists dispersal. The striated or ribbed branchlets, with verticillate whorls of teeth (representing reduced leaves) which form a collar round the joints, bear a striking resemblance to the Horse-tails (*Equisetum*) of Europe. The number of teeth in the whorl affords a useful character in classification. The family is represented by a single genus containing 29 species, most of which are endemic in Australia—13 are confined to Western Australia—but a few extend over tropical Asia from East Africa to the Malay Archipelago and South Pacific islands. In Western Australia they come second only to the eucalypts in height. The trees of the genus have a corky, corrugated bark, and some are valuable fodder-plants. The family is of special interest as forming a link with primitive vegetation, since a *Casuarina* has been recorded in the Mount Vernon Tertiary beds of North America. They occur in dry rocky country, in saline soils both coastal and inland; the largest trees mark the courses of our eastern rivers. *C. torulosa* (She-oak) is a tree of 50-70 feet, found on the coast and in the ranges of New South Wales and Queensland; it has smooth branchlets and flat-topped globular cones, and its tough wood is well adapted for furniture and veneers as well as for staves and shingles—it also burns well. For an explanation of the name see SHE-OAK. *C. stricta* (Drooping She-oak, sometimes called He-oak or Beefwood), a tree with drooping foliage which has an acid taste when chewed and is said to allay thirst, occurs in all the States except Queensland, and is a useful fodder plant in times of drought, as stock browse on it eagerly. Plants are easily raised from the seeds, which are closely packed in large ovoid cones. The timber is used for bullock-yokes, wheel-spokes and axe-handles. *C. Cunninghamiana* (River Oak), one of the largest species—it sometimes reaches 100 feet—is found in the coastal districts of New South Wales and Queensland, as well as on the dividing range and the western slopes, and

Belar.

reaches its maximum growth on the banks of freshwater rivers. It has small cylindrical cones, flattened at both ends, and very slender branchlets. It is one of the best fodder-trees in the genus. Its hard and prettily marked timber is used for shingles, staves, etc. *C. glauca* (Swamp Oak, Saltwater Swamp Oak) forms forests on the margins of salt-marshes or tidal rivers. In the latter station it acts as host for several parasitic mistletoes; one prevalent species (*Loranthus linophyllus*) has cylindrical leaves mimicking those of its host. The epiphytal Pencil Orchid

(*Dendrobium teretifolium*)—which also has cylindrical leaves—forms large clumps on the trunk, and the bark is draped with varicoloured lichens. The fruit is a small globose cone; nuts grey (in other species they are dark-brown). Its timber is useful where toughness and lightness are requisite. *C. equisetifolia* (Iron-wood, Bull Oak) is a northern species, extending to India and the Pacific islands. The bark is astringent, and has been used in cases of dysentery. The islanders dye their cloth with it, and make clubs of its wood. Its coarse-grained and beautifully marked timber lasts well when used for jetty-piles, for underground work, and for the knees of boats. In India it is used for fuel on the railways, and large plantations have been established near Madras to supply it. *C. suberosa* (Black She-oak), found in all the States except Western Australia, is a coastal or mountain species, and does not extend to the inland plains. Its timber is used for shingles, tool-handles, etc. *C. Luehmanni*, a warm-country species, ranging from Queensland to South Australia (its spread easterly is interrupted by the cold climate of the highlands of the dividing range), is easily distinguished by its broad, flat-topped cones. *C. lepidophloia* (Belah, Belar) is the commonest *Casuarina* of the interior, usually found in 'gilgai' country—i.e. low-lying land with natural basins subject to inundation. The timber is much used for fencing posts. *C. nana*, a small shrub occurring in alpine and sub-alpine regions, forms a considerable percentage of the shrubby vegetation on the bleak windswept ridges of the Blue Mountains. *C. Decaisneana*, the commonest species known in central and north-western Australia, has very large cylindrical fruits, occasionally three inches long. Its timber is very hard and resists white ants.

Cat-birds. See BOWER-BIRDS.

Catchpole, MARGARET (1762-1819), daughter of a farm-labourer, born at Seven Hills near Ipswich in Suffolk on 14 April 1762, became locally famous at the age of 24, when she galloped a spirited pony bare-back to Ipswich to fetch a physician for the sick wife of her father's employer. This exploit procured her the position of maid-servant in the family of an Ipswich brewer, Cobbold by name; but, falling in love with a young smuggler, she in 1797 stole a horse from the Cobbold stable and rode it to London (70 miles away) in 8½ hours. There she was caught, tried for the robbery, and sentenced to seven years' imprisonment. In 1800 she broke out of Ipswich gaol to rejoin her lover, but was recaptured and sentenced to death, the sentence being commuted to one of transportation for life. On 14 December 1801, according to one account, she arrived in New South Wales by the transport *Nile*, and shortly afterwards entered domestic service, being assigned as a cook to John Palmer the commissary (q.v.). Here, it would appear, she met the young botanist George Caley (q.v.), who asked her to marry him. But she was resolved never to marry: her smuggler lover had been killed in attempting to protect her against recapture in 1800, and she remained faithful to his memory.

From 1804 onwards she worked in the Hawkesbury district as a midwife, attending among others the wives of Richard Rouse (q.v.) and John Dight. During the Hawkesbury flood of March 1806 she was staying with the Dights; later in the year Rouse was made superintendent of the Parramatta lumber yard, moved with his family to the town, and left Margaret in charge of his farm. But she tired of the lonely life, returned to Sydney in October, and thence went to nurse the wife of William Faithfull, who had married a daughter of Thomas Matcham Pitt, a distant cousin of Lord Nelson's. She was thus in intimate relations with several of the best-known pioneer families of New South Wales. In December 1806 she was established in a cottage on Richmond Hill above the Hawkesbury, keeping a few sheep and goats and trading in dress stuffs and haberdashery among the neighbouring settlers. These occupations, combined with midwifery, seem to have sufficed her until she died on 13 May 1819.

The above facts are, it is believed, accurate. But the various accounts of her life are full of discrepancies: for instance, Henry Fulton, the clergyman who buried her, in his burial register recorded her age as 58 when—if we may trust her own statements—she was only just 57. It is Fulton, too, who says that she came out in the *Nile*; but official records do not admit the presence of any female convicts aboard that vessel, and Fulton may have argued that, as the Rouses came out in the *Nile*, Margaret probably came with them. Again, the earliest account of her life, written by Richard Cobbold (son of the Ipswich brewer), gives her birth-year as 1773: this was probably to heighten the romance, since the adventures of a woman of 35 who broke prison at 38 would not appeal to Cobbold's readers like those of a girl of 24-27. Margaret's name would probably have sunk into oblivion like those of the mass of her fellows had not Cobbold chosen her for a heroine and —apparently with deliberation—amalgamated her career in New South Wales with that of Mary Haydock (afterwards wife of Thomas Reiby, q.v.) a Lancashire girl who was transported in 1792 for a similar but more innocent exploit with a neighbour's pony. Cobbold in a later edition apologized for his mistake—to which the Reiby family had strongly objected; but unfortunately the Cobbold version of the story has been given in the *Dictionary of National Biography*, and therefore needs definite contradiction. Cobbold even invented letters supposed to have been written by Margaret Catchpole to friends in England years after her death. W.J.

Caterpillar-eaters. See CUCKOO-SHRIKES AND CATERPILLAR-EATERS.

Catfish, a name applied to a very large group of fishes known as the Siluroidea, which is plentifully represented in both fresh and salt waters in many parts of the world. The siluroids are armed with strong barbed spines in their pectoral, ventral and dorsal fins, with which they inflict severe wounds if handled incautiously. The mouth is encircled by long feelers (barbels), and it is from their supposed resemblance to the facial vibriciae of a cat that the vernacular name is derived. Though often regarded with repulsion on account of their scaleless and slimy bodies, catfishes are good for food, and a species that occurs in the rivers of New South Wales (*Tandanus tandanus*, commonly known as 'jewfish') is a valuable addition to the table of the man on the land. This species, like many of its allies, builds a nest of pebbles, in which its eggs are deposited and guarded by the parent fish until they hatch. Other species, such as the salmon catfishes of the family Ariidae, carry their eggs in the mouth, and even the young are so sheltered in their early stages. The salmon

catfishes have a forked tail and a small dorsal fine, whereas in other siluroids the tail is pointed and the adipose fin is lacking.

The catfish neither resembles nor is related to the marine jewfish, q.v. A.R.McC.

Cattle. *History.*—Of the few cattle first introduced from the Cape by Phillip, four cows and two bulls strayed from the settlement and were lost; the one cow left became so wild that she was killed and eaten. In 1791, however, H.M.S. *Gorgon* brought out three bulls and 23 cows, and others were obtained from India. Cattle from the Cape were always referred to as 'black cattle.' Major Johnston records the fact that the small Indian cattle, when crossed with Cape bulls, produced an offspring superior in size and quality, but bad milkers. In 1793 the public stock of cattle at Parramatta numbered three bulls, two bullocks, 15 cows and three calves. In January 1794 Collins relates that 'one small cow and a Bengal steer, were killed . . . . The beef was deemed worth eighteenpence per pound, and was sold to the soldiers. The two animals together weighed three hundred and seventy-two pounds. . . . . This was but the third time that fresh beef had been tasted by the colonists.' The same writer says 'An English cow, in calf . . . . was sold by one officer to another for eighty pounds; and the calf, which proved a male, was sold for fifteen pounds.' In November 1795, in consequence of the reported existence of the cattle lost in 1788, Hunter led a search party from Parramatta, and after crossing the Nepean 'to his great surprise and satisfaction, fell in with a very fine herd of cattle . . . . . upwards of sixty young and old' . . . . A bull was killed which 'had all the marks of the Cape cattle when full grown, such as wide-spreading horns, a moderate rising or hump between the shoulders, and a short, thin tail. . . . . It was a pleasing circumstance to have in the woods of New Holland a thriving herd of wild cattle.' The district has ever since been known as the Cow-pastures.

In 1796 the cattle (excluding the wild herd) numbered 229, and in 1800, 1044. In 1803 the government herds had 1530, and the settlers 650. In 1804 King reported a disease among the cattle, 'a spongy substance on the tongue . . . . bad feet . . . . . all those of Government's have recovered, but, I am sorry to say several belonging to individuals have died'—probably from the 'foot and mouth' disease often so disastrous later on. Referring to the breeds of cattle in the colony King stated that an Andalusian cow was left by Commodore Malaspina in 1794, and another was brought from St. Catherine's. A few were of 'the English breed from St. Helena.' In 1807 the breeds of English cattle in the colony were Longhorn, Devon, Ayrshire, Shorthorn, Red Norfolk, and polled Dun Suffolk. Probably many of the cows then introduced were shipped to supply milk on the voyage.

Macquarie in 1811 wrote:—'The Horned Cattle belonging to Government in the tame Herds are not fewer than three thousand six hundred of all Descriptions; the preserving of these tame Herds I consider to be of the Utmost Importance, and, therefore, should, in my Opinion, be persevered in for Several Years to Come, as well for the Benefit of the Crown as for the great Assistance derived from them by the new Settlers, who . . . . . by purchasing from Government at a moderate Price, and on a liberal Credit, are enabled to acquire Herds and Wealth to themselves, and to pay Government at the end of Eighteen Months or two Years, either in money or in kind, as may best suit their Convenience.' Again on 18 March 1816 he wrote:—'In consequence of the Very great Mortality which has taken place in the Government Herds, as well as in those of Individuals, during the last three Unfortunate Years of Drought, I was Induced to grant Permission to several of the great Stock-Holders in the Colony to send their Horned Cattle across the Blue Mountains to Graze in the New discovered Country and I also sent Some Herds of the Government Cattle thither as an Experiment. I have now the Pleasure of reporting to Your Lordship that both the Government Cattle, and those belonging to Individuals, have greatly benefitted Already by the Change, and the Whole Wonderfully Improved both in Size and Appearance owing to the Abundance of rich Grass and Water to be Met with in all parts of that Country.'

In 1820 there were 54,103 horned cattle in the colony. John Macarthur's according to Atkinson, were of the Lancashire, and Samuel Marsden's of the Suffolk (polled) breed; these two were perhaps the most unmixed herds in the colony. About 1840 Gipps stated that 'Our flocks and herds already stray over a country 500 miles long by 300 miles wide; and I hesitate not to say that any attempt to bring them within the limits even of our twenty contiguous counties would end in failure, if not in the ruin of the country.' The stock reported at the end of 1839 were 7088 horses, 371,699 horned cattle, and 1,334,593 sheep; the real numbers in all probability were greater.

In 1843 a financial crisis made stock almost unsaleable. At the critical moment Henry O'Brien, a squatter in the Yass district, suggested that surplus stock should be boiled down for tallow, and the hides and skins exported. This method of utilizing sheep had been already tried in 1838 by Frederick Ebsworth, an employee of the Australian Agricultural Company, and had proved profitable; it was now used also for cattle with good results, and for some years they were so treated to the extent of 40,000 per annum. The number of horned cattle in the colony was then 1,017,316; notwithstanding the bad times they increased in 1844 to 1,159,432 head. About 1862 a severe outbreak of pleuro-pneumonia occurred, so that in 1863-4 the number of cattle dropped from 2,620,383 to 2,032,522. As about that time cattle were being replaced by sheep on many stations, there was a further decrease to 1,771,809 in 1866, and in 1867 to 1,728,427. The pleuro-pneumonia was in the end checked by inoculation (great losses were at first caused by rough methods and impure virus), and in 1870 the two-million mark had again been passed.

In that year, according to an official report 'The principal breeds of Great Britain—Shorthorned or Durham, Hereford and Devon—are to be found here in perfection. Pedigree stock is much sought for and realizes high prices . . . . the colonial-bred animals are allowed to compete without restriction with the imported at Agricultural Shows, although formerly imported and colonial breeds were classed separately. . . .'

In 1895 the chief inspector of stock reported that both the quality of the cattle and the stockowners' ideas about breeding had undergone great improvement, while runs had been enclosed and subdivided, heifer-paddocks formed and large numbers of pure-bred stock, high-

priced and of high quality introduced; consequently the beef cattle of both New South Wales and Queensland could in ordinarily good seasons compare favourably with those of any other part of the world. Black polled and improved red polled herds had by that time been established in New South Wales.

The number of cattle registered in New South Wales (including the Federal Capital Territory) shows no regular growth, as the following table will testify:—

1875	3,134,086
1890	2,091,229
1905	2,337,973
1920	3,375,267
1922-3	3,251,180

Victoria.—The first cattle introduced into the Port Phillip district were taken by Edward Henty (q.v.) to Portland Bay in November 1834, and consisted of 13 heifers and four working bullocks. Shortly afterwards 16 more cattle were brought from Tasmania, and in the following year Batman and others introduced Tasmanian cattle into the Port Phillip country; not long afterwards the Sydney-side squatters began to travel their herds southwards from the Murrumbidgee and Monaro districts. In 1836 Port Phillip reported 188 head of cattle; but in 1838 there were 13,272, in 1841 50,837, and in 1843 160,792, many of which had been brought overland. Of these 45,520 were on runs in the Murray valley, 23,779 in Gippsland, 24,432 in the area bordering Port Phillip and 53,453 on the western plains.

To secure a good area of the much-desired 'western country,' it was advisable to have herds justifying the need of such an area. The demand for stock, therefore, was immense, and the price of cattle rose in proportion. In 1846 the cattle had increased to 231,602, and a considerable amount of beef was cured for export, chiefly to Tasmania. In 1850 there were 346,562 head of cattle in Victoria and the output of tallow was 10,009,246 lb., valued at £132,403. The influx of population that followed on the discovery of gold, and the substitution of sheep for cattle over a large portion of the country, tended to improve the price of cattle and encouraged the holders of cattle-runs to improve the character of their stock. The cattle originally bred in the colony consisted of shorthorns and Herefords; but the taste of Victorian breeders was always for the shorthorn, and gradually the herds of Herefords were reduced, stud herds of shorthorns were formed, and animals of high lineage were imported from England. At a later date (about 1890) polled Angus cattle were imported, and came into favour because the climate suited them. By 1870 the breeding of stud bulls was progressing, and many fine animals were exported to other colonies; the New South Wales chief inspector of stock reported in that year that 'next to English stock, the colony has been indebted to Victoria.'

In 1860 the cattle numbered 722,332 head, including 197,332 milch cows. In 1870 the total number was 776,727 head (212,193 milch cows), and of these 80 per cent were in the hands of farmers, as the best portion of the old runs had been taken up by selectors. In 1880 there were 1,286,267 head in Victoria, including 329,198 milch cows; in 1890 the total number was 1,782,978; and the number has remained fairly steady at this figure until the present time, the total for 1922 being 1,785,660; the proportion of milch cows, however, has increased considerably, from 25 per cent of the total in 1880 to 35 per cent in 1922.

Queensland.—Although Allan Cunningham opened up excellent cattle-country west of the main range in Queensland as early as 1827, it was not till 1840 that squatters took any advantage of the discovery. In that year Patrick Leslie, Arthur Hodgson, John Cox and others moved northwards from New England and the Hunter valley on to the Darling Downs, and cattle-runs soon began to spread north and west over the watersheds of the Macintyre and Condamine. By 1859 there were nearly 433,000 cattle in Queensland; within five years that number had doubled, and within 25 increased tenfold. There was great rivalry between cattle-owners and sheep-owners, as in the western States of North America, but their mutual dislike did not develop into violence. In 1890 the cattle-tick (q.v.) began to spread in the coastal districts; and in 1891 record of 6,822,401 cattle in the colony was by 1900 diminished to 4,078,191. Values also were very low—whereas in South Australia and Victoria cattle fetched from £8 to £10 per head, and in New South Wales from £5 to £8, Queensland prices ranged from £3 to £4. De Satgé's *Journal of a Queensland Squatter*, describing conditions about the end of last century, notes that on the Logan River south of Brisbane, and in the Moreton Bay district, cattle country was mainly freehold, and the cattle largely used in dairying; farther north there were many cattle-stations in the Burnett, Isaacs, and Burdekin valleys, and the Cape York Peninsula was almost exclusively taken up with cattle. On the rivers running into the Gulf of Carpentaria there was excellent cattle-country only half-stocked; the boiling-down establishments at Normanton and Burketown were primitive, and those at Townsville and Bowen out of reach. The coastal runs were well served in this respect, with factories and freezing-works at or near Brisbane, Toowoomba, Gladstone, Rockhampton, and St. Lawrence, besides those already mentioned. The inland areas were served by similar establishments at Charleville, Barcaldine, Longreach, and Hughenden. All northern and western cattle were travelled to market on the hoof.

Since 1900 the situation has not altered in essentials, though the number of cattle has increased considerably and their quality has to some extent improved. The following figures tell their own story:—

1900	4,078,191
(1902 and 1903 were drought years)	
1905	2,963,695
1910	5,131,699
1915	4,780,893
1920	6,455,067
1922	6,955,463

For many years Queensland has contained from 45 to 49 per cent of the cattle of the Commonwealth.

South Australia.—The first supplies of stock for South Australia were obtained from Tasmania and New South Wales. In 1838 the first mob of cattle arrived overland from New South Wales; this was considered an event of such importance that it deserved celebration with a dinner at which 90 guests feasted on an ox chosen from the herd. The mob comprised 335 head and was in charge of Joseph Hawden who during the journey of 10 weeks lost only four bullocks. The second mob was brought over by E. J. Eyre, and the third by Captain Sturt. In 1838 there were 2500 cattle in the colony;

two years later they had increased to 15,000, and during the next decade that number was quadrupled. In 1860 the cattle numbered 278,265, but five years later there was a great falling off; in 1870 the number was reduced to 136,832, and it took 10 years to recover and pass the record of 1860. By 1895 there were 636,824, but 280,957 of these were running in the Northern Territory, then under South Australian administration, which from 1885 onwards was being stocked from Queensland. From this time forth cattle-raising on an extensive scale was restricted to 'outside country' (i.e. to the salt-bush plains of central Australia and the Territory). In 1900 South Australia proper held 214,761 cattle; in 1910 384,862, and in 1922 425,811. Some fine stud cattle—chiefly shorthorns and Herefords—are produced in the State, the chief studs being those formed by the late J. H. Angas in 1848 with pure-bred stock brought from England by the South Australian Company.

Western Australia.—In 1832 the settlers in Western Australia had about 500 head of horned cattle; but, what with the natural increase and an importation from Tasmania in 1840 (when cows realized £21 and heifers £15 a head) the number in 1845 was 10,910 head. In 1861 vast areas of excellent grazing country were discovered along the north-west coast by F. J. Gregory (see EXPLORATION BY LAND). In 1863 live stock were first shipped from this region, and the country was soon taken up and stocked as far north as Cambridge Gulf and Kimberley. The latter district was in 1893 the best cattle-country of the colony, and held over 150,000 head. Cattle were frequently travelled across from Queensland, and a good stock-route was gradually opened up between the two colonies. By 1911, 75 per cent of the State's cattle were being raised in the north, Kimberley alone carrying five-sixths of these. Cattle were conveyed to Fremantle in specially fitted-up vessels, or might travel overland by well-watered stock-routes. Of these there are no less than 3015 miles on which the government maintains 242 wells, on the average about 12½ miles apart. The annual maintenance costs £3500, and the capital cost was about £82,500; no direct revenue is obtained from them (see WATER SUPPLY). About 23,000 head came annually by sea; a rough estimate set down the overlanded cattle at 'several thousand;' but many of the cattle travelling by both routes were brought from the Northern Territory.

In 1911 the commissioner of tropical agriculture reported that 'when compared with Queensland, Kimberley cattle are undergoing a process of deterioration. . . . On a number of runs, more particularly the smaller runs, degeneration is evident; the cattle are getting deplorably inbred and show it in reduced size, lighter skin, and weakened constitution. They mature tardily, fatten slowly and calve poorly. . . . Unless the graziers are able to introduce well-bred stud bulls the majority of the cattle will only be fit for canning, a smaller proportion for freezing, and only a few will come up to the chilled meat standard. . . The difficulty is aggravated by the presence of ticks in East Kimberley.' About the same time many station-owners, particularly in the Gascoyne district, substituted sheep for cattle, as more suitable for the class of country, and more profitable on account of the greater certainty of returns. But the consequent decline in numbers was only temporary, as the following figures show: number of cattle in Western Australia:—

1900.....338,590	1912.....806,294
1905.....631,825	1916.....863,930
1910.....825,040	1920.....849,803
	1922.....939,596

Northern Territory.—Cattle were first introduced into the Territory in 1824, when a military settlement was established on Melville Island. In 1826 the settlement had 16 head of horned cattle, and 16 buffaloes for slaughter had just been landed from Timor. During the first four years two-thirds of the cattle died in 10 or 14 days after being landed, but the survivors did very well. The Timor buffaloes herded apart from the English cattle. They were left on the island when the settlement ceased to exist, increased rapidly, and have for many years been hunted and killed for their hides.

The occupation of Raffles Bay in 1827 involved the introduction of a few English cattle and Timor buffaloes (q.v.), as did that of Port Essington eight years later. In 1841 the commandant at the latter port reported that the buffaloes were dying of the distemper, while the descendants of those left at Raffles Bay, a few miles away, were increasing rapidly. The oxen escaped this scourge. They seem to have been mostly Durhams, and in 1883 had deteriorated very little—a fact which speaks volumes for the suitability of the climate and country for cattle-breeding.

The first cattle brought overland from Queensland arrived in 1872. In 1886 the area held under pastoral lease was 270,024 square miles, and the area declared stocked 183,833 square miles. Red-water was showing itself across a belt of 130 miles between the Roper and King, and ticks were becoming troublesome. In 1892 the export of cattle to the East was initiated by a Sydney firm, aided by a government subsidy of £5000 per annum. During that year 1536 head of cattle were exported; in 1895 the number of stock shipped to the East was 2382. In 1897 the agreement terminated, the southern markets were closed owing to quarantine restrictions, and the industry fell on evil days; but in 1899 the prohibition against importing Territory cattle into Western Australia was removed, and in 1900 8490 head of cattle were exported. The Eastern market, however, had disappeared, and, though in 1909 37,492 cattle (valued at £168,261) left the Territory, the other States were the only available market.

In 1911 the Territory came under the federal government; under its auspices extensive freezing-works were erected near Darwin in 1917, and proved a boon to pastoralists, who were further aided by the railway extension from Pine Creek to the Katherine River. But labour troubles led to a dearth of shipping and ultimately to the closing of the works in 1920, and the Territory is again dependent on travelling its stock to market. Five gazetted stock-routes, aggregating 2121 miles, are well supplied with bore water.

The following figures depict the growth of Territory herds since statistics were first taken:—

1880..... 19,720	1910.....513,383
1890.....214,094	1920.....659,840
1900.....257,667	1922.....760,766

Tasmania.—The first cattle brought to Tasmania were 146 head, part of a consignment from India by the *Lady Barlow* which King sent to Collins in the spring of 1804. In the autumn

of 1805 a similar consignment was landed from the *Sydney* at Port Dalrymple, and a little later Paterson reported that the crossing of Bengal cows with English bulls gave satisfactory results. For many years the island consumed its own cattle, but in 1817 (although at that very time Sorell reported that the government herds were 'at a very low ebb, both as to numbers and quality') cattle were being exported to the Mauritius. While the climate and surroundings seem to have been suitable, farmers took less trouble over their cattle than over any other stock and they were left to depend entirely on the natural pastures. 'So defective' wrote Widowson in 1829, 'is the system of breeding that the proprietors themselves are almost indifferent about them.' In 1841 it was profitable to ship fat cattle to Hobart from Sydney, Twofold Bay, and Corner Inlet—apparently because by that time it had become necessary to provide Tasmanian herds with artificial food, so that the naturally fed Gippsland cattle were cheaper.

Of later developments there is little to say beyond noting the statistics:—

1821.....	35,000	1880.....	127,187
1828.....	84,476	1890.....	162,440
1847.....	72,454	1900.....	165,516
1860.....	83,366	1910.....	201,854
1870.....	101,459	1920.....	208,202
		1922.....	218,197

General.—Within the last 20 years a great improvement has been made in Australian herds, mainly because the industry has come to depend more and more on the export trade, both in frozen and chilled meat and in butter. Temperate Australia—i.e. in practice, the area south of the tropics and east of the 142nd meridian—has the best dairy herds and breeds the best stud cattle; the beef-producing herds, which supply both the Australian demand and the establishments that refrigerate meat for export, run chiefly in the tropical and semi-tropical areas. Queensland produces 48 per cent of the total number, and New South Wales 25 per cent. The value of the industry to the Commonwealth may be gauged by the following figures:—(1922) Number of cattle, 14,336,673, of which 2,419,809 are dairy cows; cattle slaughtered, 1,907,373: (1918-23) beef exported, 697,828,927 lb., value £12,434,537 (nearly 76 per cent went to the United Kingdom. W.S.C.

Cattle-tick, vernacular name of *Boöphilus annulatus* var. *australis,* a species of the family Ixodidae and order Acarina (q.v.). This tick is responsible for two distinct affections of cattle—the mere infestation, which causes sores and anaemia, and the fevers due to certain blood parasites (*Piroplasma* or *Babesia*) of which the tick is a carrier. Not cattle only but horses, deer, asses, and mules—less frequently sheep and goats—are included among its victims. It was probably introduced with Asiatic (Brahma) cattle from Batavia in 1872, but was first noticed through the mortality that occurred in a mob of cattle at Glencoe (104 miles SE. of Port Darwin) in 1880-1. In 1885-6 it was reported between Glencoe and the Katherine River, in 1885-7 on the Roper, and in 1890 on the Macarthur. Through the closing of the boiling-down works at Burketown and Normanton stock traffic was diverted south, and the pest appeared at Hughenden and Longreach about 1895, whence it soon extended to Rockhampton, and reached Brisbane in 1899. Notwithstanding the efforts made to protect New South Wales from infection by a fenced buffer area, the tick was discovered near Tweed Heads in 1906, and at Kyogle on the Richmond River in 1909, but has not established itself in the dry districts of the interior. Thus, while spreading along the stock-routes into Western Australia, and introduced (via Wyndham) to Fremantle, it is reported there as sporadic, probably through climatic conditions.

Life-history.—The mature female tick, detaching herself from her host, falls to the ground and lays from 2000 to 5000 eggs, which are only slightly susceptible to rain or cold, but lose their fertility if unduly exposed to direct sunlight. In

Adult male x 6. Adult female x 2½.
Cattle Tick (*Boöphilus australis*).

warm, moist weather they develop larval ticks in from two to three weeks; these collect in thousands on fences, or vegetation, and readily attach themselves to any object that brushes past. At this stage the six-legged larva is so small as to be invisible to the naked eye. After attachment to its host for about a week it casts its coat, emerges as an eight-legged nymph, matures, and after a second month is fertilized by the wandering male. Then, being half an inch long and distended with blood, the female tick drops off, and the cycle is repeated. The parasitic stage was found by Tidswell to average about 21 days.

Apart from causing tick fever, the presence of a few ticks causes little inconvenience; but a number of them on one animal produce irritation, 'tick worry,' and anaemia, thus causing intense suffering and a high rate of mortality. The parts attacked—the escutcheon, scrotum, and flanks—become inflamed and fissured; ulcerated sores, which become fly-blown, ensue, and the animals grow listless and cease feeding. Horses, if affected, rub themselves violently, bite affected parts until they bleed and lose condition.

Tick fever belongs to a class of diseases due to a minute protozoan blood-parasite; the special Australian form is *Babesia bigemina* which also causes Texas fever in America, and similar diseases in Europe, Asia, and Africa. By the name 'red-water' it was well known in the northern districts of Australia. As, however, haemoglobinuria (red urine) is a symptom common to several affections, this synonym may be misleading, since it is not constant, and many animals die from acute fever without displaying it. Tick fever can be reproduced by inoculation, but it is highly improbable that it is spread by means other than the cattle-tick. Young cattle and calves seem proof against it, but adult cattle, especially bulls, are prone to it in its most acute form. The mortality is greatest in dry weather, and least when animals are well-fed, sheltered, and watered. In some cases 90 per cent of a herd have died; and official stock-returns show a decrease in Queensland from 7 millions in 1894 to 4 millions in 1900, of which 60 per cent is probably due to tick fever. This fever also affects milk production, and many dairy farmers have been ruined by its ravages.

So far, with the exception of a few minor outbreaks in the Tweed River district, no cattle have been known to acquire tick fever

naturally in New South Wales. In Queensland inoculation with the blood of a beast containing *Piroplasma* has been almost exclusively adopted as a protection from further attacks. An inoculated beast, however, acts as a reservoir of infection, as infesting ticks extract the *Piroplasma* and thus spread the disease, which is transmitted through the egg from an infected female to the larval tick. Non-infected ticks only become infected when they feed upon an animal that has the fever; consequently ticks developing on cattle that have not suffered from the fever are incapable of spreading infection. In New South Wales, therefore, inoculation is specifically forbidden.

Of the various devices for eradicating ticks—which are fully described and discussed in *Bulletin No. 13* of the Commonwealth Institute of Science and Industry—dipping at short and regular intervals seems the most effective and expeditious. But, in spite of the results shown to follow this method in the United States, farmers in the northern coastal districts of New South Wales —where the danger of transmission from the infected herds of Queensland is greatest —still oppose the compulsory dipping regulations, and even advocate the abolition of tick-quarantine and the substitution of repeated inoculations. In 1924 it was decided that the governments of the Commonwealth, New South Wales, and Queensland should take joint action to eradicate the tick, New South Wales contributing £91,000 towards the cost, Queensland £25,000, and the Commonwealth £58,000.

Caustic Vine. See ASCLEPIADACEAE.

Caustic Weed. See EUPHORBIA.

Cedar, a name belonging properly to trees of the genus *Cedrus*, and in Australia applied to the genus *Cedrela*, but also loosely used for trees of quite different families that happen to have a timber of similar quality. The white and red cedar, both of the family Meliaceae, are dealt with in separate articles; the bastard pencil cedar, belonging to the same family, is a *Dysoxylon*. For black pencil cedar see ARALIACEAE; for brown cedar, BORAGINEAE; for pencil cedar, PHYLLANTHUS.

Cedar, Red, a genus of the family Meliaceae. *Cedrela toona*, the only indigenous species of the genus (which is widely dispersed over tropical Asia and America), is the red cedar of the eastern States, so much prized for its valuable timber. It is a lofty tree, reaching a height of 150 feet, with large sprays of flowers, dry capsular fruits, and flattened winged seeds. It yields a small quantity of a pale amber-coloured, transparent gum. In India the leaves are regarded as valuable fodder for cattle. The bark is astringent, has been found a valuable remedy in fevers and dysentery, and is considered a fair substitute for cinchona. Leather cured with the bark has a purplish colour. The flowers, called 'toon' in India, yield a rich dye. The tree was in the early days very common in the Illawarra district, but it is rapidly disappearing, except in the less accessible mountain gullies of New South Wales and Queensland. See FORESTRY.

Red Cedar.

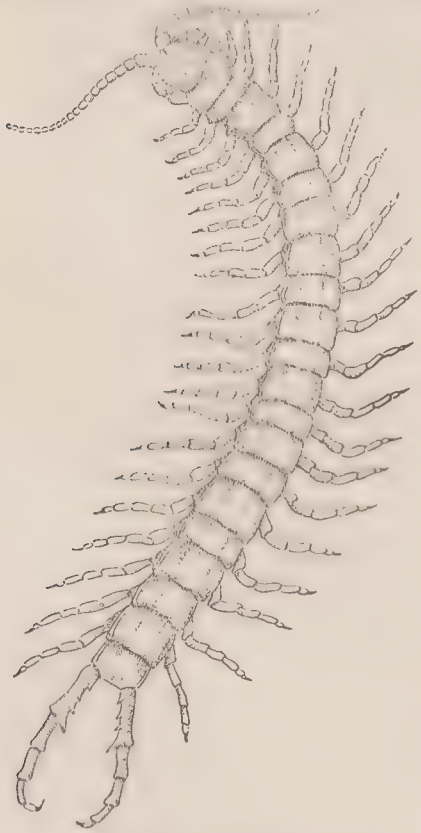
Cedar, White, a genus of the family Meliaceae. *Melia Azedarach*, the only indigenous member of the genus, is a highly ornamental tree, bearing a profusion of lilac-coloured flowers and whitish pulpy berries, much cultivated in parks and gardens as a shade-tree. It grows in coastal brush forests from the northern rivers of New South Wales to northern Australia, and extends to India. The berries are suspected to be poisonous. The Hindus use flowers, leaves and bark for medicinal purposes. The root bark is on the secondary list of the United States Pharmacopoeia an as anthelmintic. In large doses it is said to produce narcotic effects. The tree yields a gum like wattle-gum, which may be collected in considerable quantities. The timber is soft and easily worked. The rings in New South Wales specimens are very marked, and give the timber a rich, wavy appearance.

Celmisia, a genus of the family Compositae, consisting of perennial alpine or sub-alpine herbs, usually with a silvery vestiture, known as 'mountain daisies.' It is chiefly represented in New Zealand; it extends to Antarctica, and in Australia is found in masses on the Australian Alps above the 5000-ft. level. The marginal florets

are rayed; floral bracts in several rows; seeds slightly compressed, with 2-3 prominent nerves on either side; pappus bristles slender, unequal. *C. longifolia*, an eastern species with a densely tufted rootstock of long, narrow leaves, frequently forms large silvery patches in the mountain bogs of Mount Kosciusko.

Centipeda, a small genus of the family Compositae, chiefly Asiatic, consisting of low herbs. The floral bracts are in two rows, leaf-like, with scarious edges; marginal flowers rayless; seeds thick, 4-angled, usually hairy; pappus obsolete. *C. orbicularis* (Sneezeweed) is a small annual, usually found in wet places. It possesses remarkable sternutatory properties, and has been recommended as a substitute for snuff. An infusion of the plant is said to be effcacious in simple ophthalmis inflammation.

Centipedes, vernacular name of a class of arthropods (Chilopoda) which was formerly associated with the millipedes (Diplopoda) in the obsolete class Myriapoda, but has now been separated as distinctly from the millipedes on the one hand as from the insects on the other; the chief distinction consists in the position of the generative orifice, which in centipedes is at the posterior, in millipedes near the anterior,



Scolopendra morsitans.

end of the body. Further, centipedes are usually carnivorous, millipedes usually vegetarian.

The largest centipedes belong to the family Scolopendridae (popularly known as 'galley-worms'), and include a number of flat, elongated species with 21 or 23 pairs of legs; the first pair act as poison jaws, and are capable of inflicting an unpleasant, if not dangerous, bite. The terminal claws are more or less poisonous, and leave a track of inflammation if the animal is allowed to crawl over one's naked skin. *Scolopendra morsitans* is common throughout Australia, and almost cosmopolitan in range. *S. gigantea* is eight inches long. *Ethmostigmus rubripes*, the largest of our centipedes, is found also in the South Sea islands. The family Lethobiidae, with several genera, has only 15 segments. The Notophilidae are narrow, elongated centipedes, probably introduced. A familiar if unwelcome visitor to our dwellings is the single Australian species (*Allothereua maculata*) of the family Scutigeridae, variously known as 'Daddy Longlegs' and 'Hairy Nanny.' Of nocturnal habits but harmless, it feeds on flies and other insects; the writer has seen one running briskly off with a cockroach bigger than itself. The Scutigeridae are remarkable both for the ease with which they part with their legs when handled, and for their possession of compound eyes.

All centipedes have unusual quickness of movement. They are found under logs and stones, and occasionally in bedding or clothing; some species haunt the seashore, where they are at times partially submerged. Though generally regarded with revulsion, they are of economic importance as destroyers of caterpillars, wireworms and the like. In the Australian Museum at Sydney is a specimen of *S. morsitans*, with a lizard securely grasped. Some species are prettily and even strikingly marked. Nearly 80 species, belonging to 20 genera, are known from Australia.

See Brölemann in *Records of the Australian Museum*, vol. ix (1912-13).

Cephalopoda. See MOLLUSCA.

Ceratodus, a genus of fishes founded by Agassiz in 1838 to include certain fossil fish whose remains—consisting mainly of tooth-plates belonging to both jaws, each with a number of cusps on the outer margin—had been found in Jurassic and Triassic rocks from various parts of Europe. The name (from *keras*, a horn; *odous*, a tooth) was given because these cusps were supposed to resemble the antlers of a deer. Later discoveries showed that the fish belonged to a group called Dipnoi, which was dominant in Palaeozoic times but is now represented by three genera only—*Protopterus* in Africa, *Lepidosiren* in South America, and *Ceratodus* in Australia. Outside Australia very characteristic teeth of the last-mentioned genus have been found in the upper Permian formation of Texas, in the Triassic of South Africa, India, Germany, and Austria, in the Jurassic of Colorado and the Cretaceous of Algeria and Patagonia. In Australia they have been found in the lower Jurassic strata of Cape Patterson (Victoria), in the Cretaceous of Walgett (New South Wales), in post-Pleiocene deposits on the Darling Downs, and in the dry bed of a lake near Wilcannia, which is now only rarely filled with flood waters from the River Darling; here they were associated with remains of terrestrial and fluviatile animals, such as *Diprotodon*, giant kangaroos, turtles, crocodiles, and fish that are either extinct or have withdrawn to moister regions. It is now established that during Jurassic times *Ceratodus* was widely spread over the world, living in Europe side by side with the early ancestors of the marsupials. It survived in Africa and South America until Cretaceous times; then it apparently died out everywhere except in Aus-

tralia—and even here its distribution became extremely limited, owing to climatic changes that have resulted in the desiccation of large areas of the continent.

The existing *Ceratodus* (Lung-fish, Burnett Salmon) is a freshwater fish, now confined to the middle stretches of the Burnett and Mary rivers in Queensland. Until 1870 only the fossil teeth were known, but in that year a living representative of the type to which these clearly belonged was discovered in the Burnett River, and described by Krefft under the name *Ceratodus forsteri*. It had long been known to the settlers under the name of Burnett salmon, because of its red flesh, which is coarse, oily and valueless as food. Still further confusion has been caused by the application to it of the name 'barramundi;' this, strictly speaking, should be confined to a bony fish, *Scleropages leichhardti*, which does not occur in the Burnett, but is widely distributed over the more northern parts of Australia. The native name for the lung-fish on the Burnett River is stated by Semon to be 'djelleh.' In 1871 Günther, and in 1876 Huxley, described the structure of *Ceratodus;* but it was not until 1893, when the first of the large series of monographs dealing with the material collected in Queensland by R. W. Semon was published, that a complete account of its anatomy and development appeared. Meanwhile Castelnau in 1876 had described under the name of *Neoceratodus blanchardi* a new genus and species of fish, which he said came from the Fitzroy River and was very closely allied to *Ceratodus forsteri*. The latter does not occur in the Fitzroy, and the identity of Castelnau's fish is unknown: but his description of its teeth alone proves conclusively that it was quite distinct from the *Ceratodus* of the Burnett and Mary Rivers. His name of *Neoceratodus* has, however, been widely (but wrongly) adopted by many writers for the existing *Ceratodus*, to distinguish it from the fossil forms.

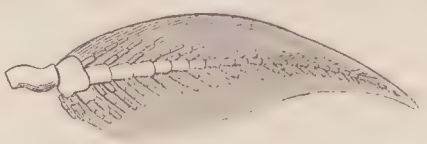
In 1891 Teller, describing the cranium of a species of *Ceratodus* from the Trias of Wurtemberg, pointed out certain differences between the skeletal structure of Mesozoic and recent forms, and suggested the retention of the original name for the former and the adoption of *Epiceratodus* for the latter. Apart from other features, such as the more primitive development of the skeleton in the living form, the number of denticles on the teeth-plates is distinctive. In typical Jurassic and Triassic species it is four in the lower and five (or four and a rudiment of a fifth) in the upper jaw. In Cretaceous forms the number is apparently never below five in each jaw, and may be six; whilst in post-Pliocene and recent forms it is six in both jaws with, in addition, the rudiment of a seventh in the upper. A similar increase in the number of denticles has been noted in certain sharks as they are traced onwards in time.

Adopting Teller's suggestion, the Dipnoans may be divided into two orders:—Ctenodipterini (in which the cranial roof-bones are small and numerous), containing only fossil forms, such as *Dipterus, Phaneropleuron,* and *Ctenodus;* and Sirenoidei (in which the cranial roof-bones are large and few), containing the living genera *Protopterus, Lepidosiren,* and *Epiceratodus* and the extinct genera *Ceratodus* and *Gosfordia*—the latter imperfectly known from the Triassic beds of New South Wales. Two remarkable features of the Dipnoi are (1) the large amount of specialization in the group at a very early geological period, (2) the extraordinary persistence of certain types.

Epiceratodus, then, is represented by only one living species, *E. forsteri* (Krefft). The body is covered with large, overlapping, cycloid scales; the tail is diphycercal, the fin running evenly all round it; the paired limbs are lobate and not fringed as in *Lepidosiren,* nor are there external gills as in *Protopterus.* The mouth is small and narrow, with fleshy lips; the external nares are on the under-side of the snout; the gill-cover has large scales, and the gill-openings descend to below the pectoral paddle, the entrance being covered by a cutaneous fringe. Externally its form is distinctly piscine; but the structure of

Lower Jaw of *Epiceratodus forsteri.*

its internal organs—more especially in regard to the circulatory and respiratory systems—indicate that it may be regarded as in some respects a transitional form, giving us hints of the possible modification of a water- into a land-animal. The mouth has no marginal teeth, but possesses a pair of chisel-shaped vomerine teeth and the very characteristic palatal dental plate in the upper, and splenial plate in the lower jaw. The internal nares open—as in no other fish, but as in amphibia—on the roof of the mouth; the rudiment of a tongue is present, and (as in sharks) the intestine possesses a spiral valve. In regard to the skeleton the skull is autostylic, i.e., the mandible articulates directly with the skull, as in *Chimera;* the notochord is persistent; the cartilaginous cranium is strongly developed and roofed by dermal bones; maxillae and pre-maxillae are absent, and, to carry the upper tooth-plates, the palatopterygoid bones are strongly developed and fuse with the skull in front and behind. The fins are characterized by the pre-



Pectoral Fin of *E. forsteri.*

sence of a median axis with paired radials, forming an archipterygium, as in the extinct Devonian Dipnoan fish *Dipterus.* The respiratory and circulatory systems reveal structures annectent on the one hand with sharks and on the other with amphibians. The gill-clefts are five in number, each of the four branchial arches bearing a complete double row of highly developed lamellae; this indicates the functional importance of the gills. The air-sac, or swim-bladder, arises from the under-side of the oesophagus and, passing immediately round the right side, runs backwards above the alimentary canal. In *Protopterus* and *Lepidosiren* it is completely double; in *Epiceratodus* it is a single sac, but down the central line, both dorsally and ventrally, there is a smooth, broad band of connective tissue separating two

lateral series of 'air cells,' the walls of which are strongly sacculated to afford a wide area for the distribution of the pulmonary veins and arteries. In *Protopterus* the structure of this organ is more highly developed than in *Epiceratodus*, and there can be no doubt that the lung of air-breathing vertebrates is a direct modification of the air-sac or swim-bladder of primitive fishes, in which it served perhaps mainly a hydrostatic and certainly not a respiratory function. The circulatory system shows a remarkable mixture of piscine and amphibian features. The heart is more or less distinctly three-chamber, with two auricles and one ventricle. The afferent arteries to the gills arise, close-set, from a *conus arteriosus* suggestive of those of primitive amphibia. The gill circulation is essentially piscine, except that from the last efferent artery on each side a vessel containing blood that has already passed through the gills on the fourth branchial arch arises and runs back to the lung. Two pulmonary veins, one corresponding to each half of the lung, return the blood into the left half of the auricle. Another striking feature is the presence of a left posterior cardinal vein, just as in fishes, and side by side with this a post-caval vein, as in amphibia. The blood from the tail region is carried forward by the caudal vein, which divides into two branches, each of which receives veins from the kidney. One of these passes on as the left posterior cardinal; the other runs along the lower side of the right testis, and then passes to the middle line and enters the *sinus venosus*, having the same relation to the liver and hepatic veins as the post-caval of amphibia.

In regard to their habits the Dipnoi vary much. *Protopterus* and *Lepidosiren* bury themselves during dry seasnos in burrows in the mud, leaving an opening at the end for breathing through. *Epiceratodus* never leaves the water. It is quite incapable of movement on land, and spends its time either lying on the bed of the stream or moving about sluggishly, day and night alike, in search of its mixed diet—seeds and fruits of gum and tea-tree and water-plants, with small crustaceans and molluscs that live amongst the latter. During the rainy season the Burnett flows between deep banks with, in flood-time, a depth of 30 to 40 feet; but during dry seasons it may be reduced to a series of disconnected water-pools, foul with decomposing animal and vegetable matter. It is under these conditions that the lung is of special use.

The opercular cavity is filled and emptied about 12 times every minute; and at all seasons the fish comes periodically to the surface every 30 or 40 minutes, projects the tip of its snout, and empties and refills its lung, at the same time making a slight groaning noise. When the water is putrid, this power of breathing enables *Epiceratodus* to remain alive and active when all other fish in the same pool perish.

Spawning takes place principally in September and October; each egg is deposited separately amongst (but not attached to) vegetation, and surrounded, like those of a frog, with a coating of jelly. These eggs, which finally lie on the mud, are extremely fragile, and very sensitive to changes in the temperature or purity of the water. The early stages show a general resemblance to those of amphibia, but there is no larval metamorphosis; the tail is diphycercal from the first; the limbs always have the archipterygial form, the pectoral appearing at the third and the pelvic not until the tenth week. At nine weeks old the young are one inch long; at seven months, two inches. It is calculated that a 30-inch specimen is 20 years old and—as the growth-rate lessens in later years—exceptionally large specimens, which may measure six feet, must be of great age. See Plate xii. W.B.S.

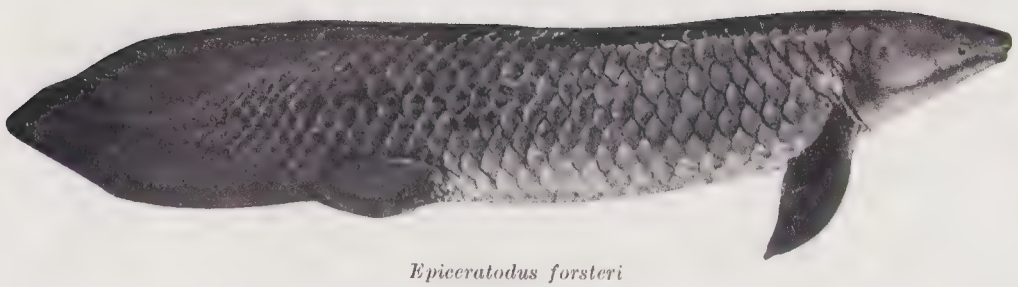
Ceratopetalum, a genus of the family Cunoniaceae, consisting of trees or shrubs; its three species are endemic in eastern Australia. The calyx-lobes are 5, persistent; petals small or none; stamens 10, the small anthers with a recurved appendage; styles united at the base; fruit small, hard, dry, surrounded at the base by the wing-like calyx-lobes; seeds solitary. The genus includes the Christmas bush and coachwood of New South Wales.

Cerbera, a small genus of the family Apocynaceae, dispersed over tropical Asia and Malaysia. *C. odollam,* the only Australian representative of the genus (which extends from Queensland to northern Australia, in all cases on the coast) is a tall bush with thick soft branches; flowers white to yellow, in dense clusters, sweetly scented; fruit large, with a slightly succulent outer and a woody inner coat. Its habitat being coastal, frequently on the edge of tidal waters, the large fruits are specially adapted for prolonged life in the water. The kernel contains a narcotic poison, and the bark is purgative. In Java the leaves are used as a substitute for senna. In India an oil used for burning is extracted from the seeds.

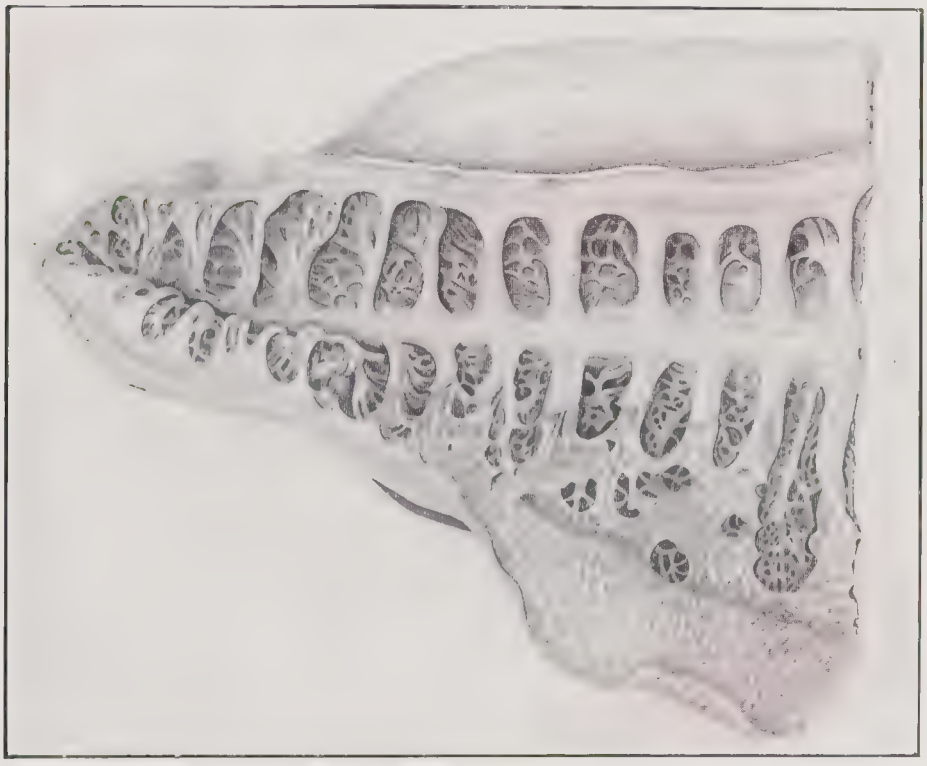
Cerretti, Bonaventure, born at Orvieto in Italy in 1872 and educated at the pontifical seminary in Rome, was ordained priest in 1895, held the chair of classics at the seminary from 1898 to 1900, and in 1901 was attached to the papal secretariate of state. In 1904 he was sent to Mexico as secretary to the apostolic delegate there, in 1906 was made *Uditore* to the apostolic delegation at Washington, and on 19 July 1914 was consecrated archbishop of Corinth and made first apostolic delegate to Australasia. His capable administration of this office led to his recall in 1917 to be appointed secretary of the congregation for extraordinary affairs, in which capacity he was entrusted in 1919 with negotiations with the victorious allied powers regarding Catholic missions in the colonies formerly German. His success, and the general esteem it brought him, led to a further commission in June 1921, when at the resumption of official communications between the Vatican and the French government he was made papal nuncio at Paris. E.M.O'B.

Chafers. See Beetles.

Chaffey, George, a Canadian irrigation expert who, with his brother William, during the seventies and early eighties of last century directed various irrigation enterprises in California. There Alfred Deakin, travelling as a royal commission on water-supply, met them in 1883, and induced them to consider Australia as another field for irrigation. An agent was at once sent to Victoria to prospect the country, and in 1884 George Chaffey came over, selected Mildura on the Murray (just above the junction of the Darling) as a suitable spot, and after some bargaining entered into an agreement with the Victorian government for the gradual settlement of 250,000 acres to be fed by water withdrawn from the Murray. His brother joined him in 1886. The progress of this settlement is narrated under Irrigation. At first the nominally



Epiceratodus forsteri



Lung of *Epiceratodus forsteri*

Chocolate Bat (Bag-tailed)

controlling body, the Mildura Irrigation Company, was itself controlled by the Chaffeys; as settlement proceeded, it was handed over to the settlers, who have ever since controlled their own destinies through an elective body known as the Mildura Irrigation Trust. William B. Chaffey still (1925) grows fruit in Mildura. George Chaffey afterwards became identified with large banking interests in California, as well as with the Imperial Valley irrigation project in the United States.

Challis, JOHN HENRY (1809-1880), son of a military officer, was born in England in 1809, but migrated to Sydney in 1829 and was employed as a clerk by Marsden and Flower, general merchants. In 1842, the firm having been reorganized after Marsden's death, Challis was taken in as a partner 'on his merits, and it is believed without capital' says H. E. Barff in his *Short Historical Account of the University of Sydney*. The new firm—Flower, Salting & Co.—became extremely wealthy when the gold discoveries expanded Australian commerce, and in 1855 was dissolved, the partners retiring on their acquired wealth, which in Challis's case amounted to more than £100,000. This included not only personal property and shares, but a large block of land along the shore of Woolloomooloo Bay, extending eastwards to Macleay-street. After retiring, Challis lived almost wholly in England (except for a short visit to New South Wales in 1859), and took little interest in public affairs apart from education. In the university of Sydney, however, he was always interested; in 1856 he gave a stained-glass window for the great hall, and at his death left by will to the university the whole of his residuary estate, subject to the widow's life interest and a five-year period of accumulation after her death. He died in France on 28 February 1880, and his widow in 1884; in 1890, therefore, the university funds were increased by about £200,000, a sum which was increased in 1905—when the last of certain annuities fell in—by nearly £80,000. From this bequest funds were provided for seven new professorships and four law lectureships. See UNIVERSITIES.

Chalmers, JAMES (1841-1901), born at Ardrishaig in Argyllshire on 4 August 1841, leaving school entered a lawyer's office in Inverary, but when 15 years old determined to be a missionary and in 1861 joined the Glasgow City Mission. Acting on the advice of Dr. Turner of Samoa, he offered his services to the London Missionary Society and entered Cheshunt College in 1862 to take up special studies. On leaving Cheshunt in June 1864 he spent a year in a students' home, and then began the study of Raratongan with George Gill. Ordained to the Congregationalist ministry in October 1865, he in January 1866 sailed in the second *John Williams* for Raratonga, arriving on 20 May 1867 after a voyage full of mishaps, the last stage of which was made in a brig of 150 tons, commanded by 'Bully' Hayes. In the islands he was always known as 'Tamate' —the native version of 'Chalmers.' While at Raratonga he started a monthly newspaper, and waged relentless war against drunkenness; but he desired closer contact with unconverted heathendom, and in May 1877 was transferred to New Guinea. Here during his first exploratory trip (1878) he visited over 100 villages, hardly any of which had previously seen a white man, and moved unarmed and fearless amongst the most ferocious cannibals. His missionary work for the next seven years involved a great deal of detailed exploration which proved politically and commercially valuable; he thoroughly examined the northern bight of the Gulf of Papua, and in 1879 discovered the Purari delta. Before he left the island in 1886 he had planted a series of mission stations along the Gulf from its head eastwards to the Louisiades. He did not approve of the premature annexation of Papua in 1883 by the Queensland government; but when in 1884 the British government decided to establish a protectorate over south-eastern New Guinea, Commodore Erskine and Vice-admiral Bridge warmly acknowledged the help given them by Chalmers and his fellow-missionary Lawes, and recommended that they receive some recognition; the recommendation was ignored. In 1886 Chalmers visited England, where to his surprise he was lionized and sought after as a missionary deputation. On his return to Papua he spent several years in visiting stations, but in 1892 settled at Motumotu, west of Port Moresby, intending to explore parts of the country still unknown; thus he went up the Fly River as far as Howling Point, and blazed tracks into many savage districts. In 1894-5 he revisited England for the Centenary of the London Missionary Society, and was presented with the freedom of the ancient royal burgh of Inverary. On 4 April 1901 he left Daru Island for a trip to Godaribari Island, west of the Aird delta. The natives crowded the *Niue*, and Chalmers, to get them away, arranged to go ashore next morning. In the morning, therefore, he and a fellow-missionary entered the long house, where they were attacked from behind with stone clubs, their heads were cut off, their bodies hewn in pieces, and eaten the same day. The massacre was prearranged. In a letter to his mother Stevenson described Chalmers (who had visited him at Samoa in 1890) as a 'man nobody can see and not love. He has plenty of faults like the rest of us; but he's as big as a church.' His writings comprise *Work and Adventure in New Guinea* (1885) written in collaboration with W. W. Gill, *Pioneering in New Guinea* (1887), and *Pioneer Life and Work in New Guinea* (1895). After his death his friend Lovett published his *Autobiography and Letters* (1902) and a biography *Tamate* (1904). J.C.

Chamaelaucium, a genus of the family Myrtaceae, endemic in Western Australia. The calyx-tube is bell-shaped, 10-ribbed, 5-lobed, the lobes usually petal-like; petals 5, orbicular; stamens 10, shortly united in a single row; fruit formed of the hardened base of the persistent calyx. *C. uncinatum* (Geraldtown Wax Flower), a shrub with large pink and white flowers, is very adaptable, easily cultivated from the seeds and highly ornamental.

Chambers, CHARLES HADDON (1860-1921), born at Stanmore near Sydney on 22 April 1860, educated at Fort-street school and appointed to the public service at the age of 15, soon abandoned it for insurance canvassing, station life, and travel overseas. For a short time he managed the Montagu-Turner opera company, but in 1882 settled in London as a free-lance journalist and playwright. In 1888 his play 'Captain Swift' was a London success, and 'The Idler' (1890), 'John-a-Dreams' (1894), and 'The Tyranny of Tears' (1899) established him as a sound and competent dramatist. During the war of 1914-18 he was employed on propaganda work, and made ten visits to the United States; his comedy 'The Saving Grace' was written with this work in view. He never revisited Aus-

tralia, but to the end of his life dreamt of doing so, and considered himself an Australian. He died on 27 March 1921.

Champ, William Thomas Napier (1808-1892), born at Maldon in Essex on 15 April 1808 and educated at the Royal Military College, Sandhurst, entered the army on 16 November 1826 as ensign, and in October 1828 reached Sydney with a detachment of his regiment, the 63rd. In 1829 the detachment was shifted to Tasmania, where the rest of the regiment joined it. He served for a time at Macquarie Harbour, and in 1830 took part in Arthur's attempt to 'drive' the natives down to East Bay Neck. In 1832 Champ, then stationed at New Norfolk, was commissioned lieutenant in the 39th regiment, but remained attached to the 63rd; and, when that regiment left the colony in January 1834, he went with it to the Mauritius. In 1837 he returned to settle at New Norfolk, where he became assistant magistrate, then chairman of a board appointed to investigate affairs at Port Arthur, and finally an efficient and humane comptroller-general of convicts—a position from which he retired in 1848. When in November 1851 H. S. Chapman (q.v.) resigned his position as colonial secretary under Denison because he disagreed with the official pro-transportation policy, Champ was his successor; in November 1856, when responsible government was conferred on the colony, he (having been elected one of the members for Launceston) became the first Tasmanian premier, and at the same time was given £6000 as compensation for loss of the permanent office. After four months in office he was defeated on a vote to reduce the governor's salary, abandoned politics (for which he had no taste), and settled in Melbourne, where in July 1857 he succeeded John Price (q.v.) as inspector of prisons and head of the penal department. The reforms he introduced, while not specially scientific, did away with many notorious abuses, and greatly improved both the effectiveness and the rationality of the system. He held the post until 31 December 1868, and then retired on a pension. During these years he joined the local defence forces as lieutenant-colonel, retiring as colonel. In 1871 he re-entered politics as member of the assembly for the East Bourke Boroughs, but resigned his seat after two sessions. He died in Melbourne on 25 August 1892.

Channelbill. See Cuckoos.

Chapman, Henry Samuel (1803-1881), born at Kennington in Surrey on 21 July 1803 and educated at Bromley in Kent, in 1823 migrated to Canada, where he founded and edited the first Canadian daily newspaper, the Montreal *Daily Advertiser*. Returning to England at the end of 1834, as a delegate from Canadian reformers who wished to obtain representative government for their colony, he joined the Wakefield-Buller group of politicians, and established friendships with Cobden and John Stuart Mill; he expounded publicly the Wakefield principles of colonization with special reference to New Zealand, was called to the bar in 1840 to become advocate to the New Zealand Company, wrote the article on New Zealand in the seventh edition of the *Encyclopaedia Britannica*, and in 1843 migrated to New Zealand on appointment as judge of the supreme court there. On 29 July 1851 he was made colonial secretary of Tasmania, but quarrelled with the governor over the transportation question (he himself being an anti-transportationist) and resigned his post in November of the same year. During a subsequent visit to England he refused a West Indian governorship. Returning to Hobart, he in November 1854 left that town for Melbourne, where he was admitted to the Victorian bar and came into notice for his share in defending the Eureka Stockade rioters; in February 1855 he was elected to the old legislative council, and in 1856 to the new assembly, where he identified himself with the Duffy-O'Shanassy group, and was O'Shanassy's attorney-general in the ministries of 1857 and 1858-9—the second of which he formed. In O'Shanassy's third ministry (1861-3) he had no place, but towards the end of its course was made acting judge in equity during the absence of Sir Redmond Barry. During his stay in Victoria he also for some time acted as lecturer in law at the local university. In 1864 he returned to New Zealand, again as judge of the supreme court for the province of Otago; this position he held until 1875, when he retired on a pension and busied himself with educational affairs, being towards the end of his life chancellor of the university of Otago. He died in Dunedin on 27 December 1881.

Chapman's particular gift to Australia was the Australian ballot (see Ballot, Voting by). When late in 1855 William Nicholson brought in a resolution in favour of election by secret ballot, Chapman voted in favour of it, and proceeded to draft the clauses defining the method of applying it. These clauses are given in full in the *Victorian Historical Magazine* (vol. viii, pp. 54-5); apart from the provisions for secrecy their essence is that the voter strikes out the names of all candidates for whom he does not wish to vote. Though introduced by Nicholson, they are certainly the work of Chapman; and to him is due the credit of inventing a workable scheme of voting, which has since been adopted in most parts of the English-speaking world.

Chats. This name is applied in Australia to an endemic family (Ephthianuridae) of small perching birds, quite unconnected with the chats (Saxicolidae) of Europe and Africa. They are attractive little birds, mostly ornamented with bright colours, and often met with in small parties—chiefly in open country with scattered bushes. Their nests are cup-shaped, composed of grass and lined with hair, and placed in a low bush or tuft of grass. When nesting, they display great anxiety if an intruder approaches, and in their endeavours to attract him away from the locality they pretend to be wounded, fluttering along the ground and uttering notes of distress. This habit—well known among ducks and plovers—is very rarely displayed by perching birds other than the Australian chats.

In all the species the sexes differ considerably in plumage, the male being more brightly coloured. The commonest throughout southern Australia is the White-fronted Chat (*Ephthianura albifrons*), known by a number of local names, the commonest of which are probably 'nun' (from the white head of the male) and 'tang,' an imitation of the note. The plumage in this species is white, black, and grey. The Crimson-breasted Chat (*E. tricolor*) is distinguished by the feature from which it gets its name. It occurs throughout Australia, but in the south is much less common than the former species. The other members of the family are confined to almost entirely the inland districts, the Orange Chat (*E. aurifrons*) occurring in

the drier parts of the southern States and the Yellow-breasted Chat (*E. crocea*) ranging across the north.

An interesting bird from central Australia, only discovered in 1911 and probably a member of this family, is the Desert Chat or Gibber-bird (*Ashbyia lovensis*), which appears to be confined to the gibber plains in the Lake Eyre basin. It is delicate brown above, with a yellowish breast. W.B.A.

Chauvel, Sir Henry George, born at Tabulam on the Clarence River in New South Wales on 16 April 1865 and educated at the Sydney and Toowoomba grammar schools, in 1886 joined the New South Wales cavalry regiment and (except for a short term with the Queensland police in 1894-5) has followed the military profession ever since (2nd lieutenant, 1886; lieutenant, 1890; captain, 1896; major, 1899; lieutenant-colonel, 1909; colonel, 1913; brigadier-general, 1914; major-general, 1915; lieutenant-general, 1917). In 1896 he was appointed to the Queensland permanent staff, in 1899 went to the South African war as adjutant of the first Queensland contingent, and rose to command a mounted infantry battalion and the 7th Commonwealth light horse. In 1902 he obtained a brevet lieutenant-colonelcy. In 1903 he was made staff officer for the light horse regiments in South Australia; in 1911 he became adjutant-general to the Australian military forces, and in 1914 was sent to the war office as Australian military representative, but had not reached London when the Great War broke out and he was at once appointed to command the 1st light horse brigade. It was mainly his report on the state of the winter training camps on Salisbury plain, brought to Kitchener's notice by Sir George Reid, that procured the decision to train the Australian forces in Egypt.

Chauvel joined the brigade on its arrival in Egypt, trained it there, and took it as a dismounted corps to Gallipoli, where he gained a reputation for shrewd leadership, and on 6 December was given temporary command of the 1st infantry division. After the evacuation he was given his choice of taking this division to France or remaining with the light horse, and without hesitation stayed in Egypt. On 16 March 1916 he took command of the Anzac mounted division, which he led at Romani and throughout the advance into Palestine. At the first battle of Gaza the Imperial mounted division was also put under his command, and on 22 April 1917 (after the second battle of Gaza) he succeeded Sir Philip Chetwode in command of the desert column. In August the column was reorganized as desert mounted corps, of three (afterwards five) divisions, including cavalry from Britain, Australia, India, New Zealand, and France; and Chauvel, as its commander, became the first Australian soldier to reach the rank of lieutenant-general. This corps—the largest body of cavalry employed in modern times under a single commander—he led to victory at Beersheba (31 October 1917) and Megiddo (19-20 September 1918) and into Damascus, then capturing Aleppo (25 October) with the 5th—mainly Indian—division. Of Chauvel's work in this last advance through Palestine H. S. Gullett (*Sinai and Palestine*, p. 782) says:—'Chauvel's work with his three cavalry divisions was the dramatic and dominating feature of the advance; and here again it was the faultless planning, and the rare success of the Australian leader in synchronizing the work of his scattered columns . . . . which dismayed and overwhelmed the enemy.' Returning to Australia in 1919, he was on 10 December made inspector-general of the Australian military forces, and on 11 June 1923 became also chief of staff. (C.M.G., 1900; C.B., 1916; K.C.M.G., 1917; K.C.B., 1918; G.C.M.G., 1919. Also holds the Order of the Nile, 2nd class, and the Croix de Guerre.)

Cheeke, Alfred (1811-1876), born at Evesham in Worcestershire in 1811 and educated privately, became a student at Lincoln's Inn in November 1831 and was admitted to the bar at the Middle Temple on 29 January 1836. In the following year he migrated to Australia, reaching Sydney in October. In November he was admitted to the local bar, in 1838 became a magistrate, and in 1841 was made a commissioner of the court for investigating land claims and crown prosecutor for the county of Cumberland. At the sittings of quarter sessions on 2 January 1844 it was pointed out that the legislative council had on a constitutional point refused to vote the crown prosecutor's salary, and the clerk of the peace for a few days performed his duties; but Cheeke's appointment, having been confirmed by the crown in 1842, could not be superseded, and in the end he resumed his work as prosecutor in the hope that the council would reconsider its decision. In January 1845 he became commissioner of the court of requests and in 1851 chairman of the court of quarter sessions. At the first election under 'responsible' government in 1856 he was induced to stand for the electorate of Cook and Westmoreland, but was defeated by James Martin and never touched politics again. In 1858 he was the first district court judge appointed under the act of 1858; and in June 1865 he was made a puisne judge of the supreme court, the only man ever raised from the district to the supreme court bench. He died while still in active employment on 14 March 1876.

Chelmsford, Viscount. Frederic John Napier Thesiger, 1st viscount, grandson of Lord Derby's lord chancellor (1858-9 and 1866-8) and son of the Lord Chelmsford who fought in the Zulu war of 1879, was born on 12 August 1868, educated at Winchester school and Magdalen College, Oxford (B.A., 1891; M.A., 1894), and called to the bar at the Inner Temple in 1893. From 1900 to 1904 he was a member of the London school board and in 1904-5 of the London county council. In 1905 he succeeded his father as third baron Chelmsford, and was appointed governor of Queensland (1905-9) and later of New South Wales (1909-13), in both States impressing himself on the community as a courageous governor and an able and learned promoter of intellectual and scientific achievement. In 1913 he returned to England, and was chosen during the year an alderman of the London county council; but in 1916 he was recalled to the public service as viceroy of India (where he was at the time serving with his territorial regiment), and in that capacity not only brought India through the grave dangers of the war but initiated reforms (known as the Montagu-Chelmsford scheme) which were intended to make it eventually one of the self-governing Dominions. In 1921 he was succeeded at Delhi by Lord Reading, returned to England, and was created a viscount. In January 1924 he became first lord of the admiralty in the Ramsay Macdonald ministry, the first Labour ministry of

Britain. (K.C.M.G., 1906; G.C.M.G., 1912; P.C., G.M.S.I., G.M.I.E., 1916; G.B.E., 1917.)

Chelonia. See TORTOISES AND TURTLES.

Chenopodiaceae, a very large family of plants spread over the greater part of the globe, but most abundant in saline habitats. Thirteen genera, with 146 species, are indigenous to Australia. The genus *Salicornia* has 9 indigenous species. *S. australis* (Samphire or Glasswort) may be found anywhere along the coast-line in salt-marshes and estuaries, and extends to New Zealand. It is a leafless perennial herb, with succulent, jointed stems; the uppermost joint forms the flower-spike, in which the insignificant flowers are embedded. At maturity this joint falls off with the seeds in situ, and floats away on currents that distribute the seeds on other shores. The genus *Suaeda* has one indigenous species, *S. maritima* (Seablite), with a cosmopolitan range. It is a short-lived plant (biennial), frequently associated with the samphire, and produces a succulent berry. Most of the other genera are discussed under SALTBUSHES.

Chermside, SIR HERBERT CHARLES, born at Wilton near Salisbury on 31 July 1850 and educated at Eton, joined the royal engineers in 1868 (lieutenant, 1870; captain and major, 1882; lieutenant-colonel, 1885; colonel, 1887; major-general, 1898), and from 1877 to 1899 served in various capacities in the Near East. In 1882 he was in the Egyptian expedition, in 1884-5 at Suakin as governor-general of the Red Sea littoral, and from 1886-8 had charge of the Nile frontier of Egypt, commanding the Egyptian troops in the Sarras fight of April 1887. He then became consul in Kurdistan (1888-9), military attaché at Constantinople (1889-96), and British military commissioner in Crete (1896-9); returning to England, he was given charge of the Curragh district, and in 1900 went to South Africa in command of the 14th brigade and, later, of the 3rd division. In 1901 he was made governor of Queensland, but retired in October 1904. (C.M.G., 1880; C.B., 1886; K.C.M.G., 1897; G.C.M.G., 1899.)

Cherry, a name applied to several indigenous trees and shrubs outside the genus *Prunus*. The brush cherry may be a *Eugenia* or a *Trochocarpa;* the Herbert River cherry is an *Antidesma;* the native cherry (q.v.) is an *Exocarpus,* as are several other 'cherries;' the white cherry is a *Schizomeria.*

Cherry-tree Borer. See MOTHS.

Chevalier, NICHOLAS (1828-1902), born on 9 May 1828 in Petrograd—where his father (a Swiss) held an important position in the Czar's household—was trained as an artist in Lausanne and as an architect in Munich, studied lithography under Grunner, and in 1852 exhibited two water-colours at the Royal Academy. He also illustrated Layard's *Nineveh,* and designed the setting for the Kohinoor diamond. He continued his studies in Rome in 1853-4, and in 1855 visited Australia to look after investments of his father's. He was the first cartoonist employed by Melbourne *Punch,* introduced Australia to chromolithography, and took up painting in oils, winning in 1864 with 'The Buffalo Ranges, Victoria' a prize of £200 offered by the trustees of the Melbourne gallery for the best picture painted by a resident artist. In 1867-8 he visited New Zealand, and made a number of sketches which were shown at the Paris exhibition of 1868 and afterwards presented by his widow to the government of New Zealand. In 1868 he returned to England with the Duke of Edinburgh in H.M.S. *Galatea*: he then settled in England, executed many commissions for the royal family (including a picture of the Duke of Edinburgh's wedding), and worked steadily until 1886, when gout and other illnesses incapacitated him. He died in London on 14 March 1902.

Childers, HUGH CULLING EARDLEY (1827-1896), born in London on 25 June 1827, and educated at Cheam school, Wadham College, Oxford, and Trinity College, Cambridge (B.A., 1850; M.A., 1857), migrated to Melbourne immediately after taking his first degree, and in January 1851 was made an inspector of schools. In September of the same year he became secretary to the education department and (curiously enough) immigration agent; in October 1852 he was made auditor-general (which gave him control of the colonial revenues and a seat in the council), and as such carried through the act creating the university of Melbourne, of which he became first vice-chancellor; in December 1853 he was transferred to the collectorship of customs, retaining his seat in the council and becoming a minister of the crown—a position which he retained after the advent of responsible government, being member for Portland and commissioner of trade and customs in the first Haines ministry. He left the ministry in February 1857 to become Victoria's first agent-general. This appointment, however, fell through at the year's end on account of a change of ministry in Victoria; and Childers, after a short visit to Australia to negotiate a railway loan, entered British politics as member for Pontefract (1860-1885). Appointed chairman of a select committee on transportation and member of a royal commission on penal servitude, he soon made his mark in parliament and took minor office under Lord Palmerston (1864-6), while in the Gladstone ministry of 1868 he was first lord of the admiralty (1868-71) and after a short retirement for private reasons chancellor of the duchy of Lancaster (1872-3). In the second Gladstone ministry he was secretary for war (1880-2)—during which period he instituted the territorial system of army reform and abolished flogging—and chancellor of the exchequer (1882-5). Standing as a home ruler, he lost his seat at Pontefract in 1885, but was elected by South Edinburgh in January 1886, and in the brief third Gladstone ministry was home secretary. His health now began to fail; in 1892 he left active politics altogether, and died on 29 January 1896.

Among his other political successes was the conclusion in 1885 of the London convention which settled the finances of Egypt for a generation. He maintained his interest in Australia for many years, was agent-general for Victoria a second time in 1872, and from his appointment in 1857 to membership of a Victorian select committee on the subject remained a firm believer in the necessity of Australian federation.

Chilopoda. See CENTIPEDES.

China Naval Contingent. On 28 June 1900 Sir William Lyne, then premier of New South Wales, received a cable from the colonial office suggesting that vessels of the Australian squadron should be sent to China to take part in the Boxer war. Lyne agreed, and also offered

for active service a contingent of the naval brigade which had been intended for South Africa; and the *Wallaroo* left Port Jackson on 2 July for China. Meanwhile the government of South Australia offered the *Protector*, with or without a crew, and the Victorian government offered 200 men with field guns. All offers were accepted, and on the 19th it was announced that the Imperial government had requisitioned the Aberdeen liner *Salamis* to carry the naval contingent to China. She was at once taken over by the naval department, fitted up for troops, and left Sydney on 8 August with a contingent comprising 200 men from Victoria under the command of Captain Tickell, R.N., and 260 from New South Wales with Captain Francis Hixson, R.N., in command. The *Protector* was declined with thanks on 30 July, but the admiralty reconsidered its decision, and on 2 August cabled acceptance; Captain Creswell (previously of the South Australian naval forces, but then in Queensland) was appointed commander, and the *Protector* with 96 officers and men left Sydney on 11 August.

On 26 August at Hong Kong Captain Hixson handed over command to Captain Gillespie, R.N. The contingent was inspected at Woosung, and reached Taku on 9 September and Tientsin on the 16th; here Lieutenant Hixson and 50 men were installed in the Lama temple, Lieutenant Roberts and 50 men in the British legation, and the remainder at headquarters in the Tartar city. On the 24th Captain Gillespie and a detachment of 300 men were placed under General Lorne Campbell for an attack on the Pehtang forts, but the work had been done by the Germans before the rest of the allied force came up.

Australian naval police effected striking improvement in Tientsin streets, and were complimented on their success. On 10 October the New South Wales contingent was sent to Peking, where they stayed for the winter. About 12 January a small party under Lieutenant Spain went to Kao-li-ying (a Boxer centre) to collect a fine, and destroyed a Boxer temple. The Victorian contingent remained at Tientsin, where their police work proved so valuable that permission was asked to retain them longer. A detachment joined General Ballond's expedition to Pao-ting-fu. The whole contingent received commendation on all hands for smart, soldierly bearing and invariable good conduct. The contingent returned to Australia by the transport *Chingtu*, which left Tientsin at the end of March and arrived at Sydney on 25 April 1901. The *Protector* was employed almost entirely in the Gulf of Pechili, carrying despatches and doing survey work. She left Hong Kong on 24 November, and reached Adelaide on 8 January, when the crew was paid off.

Chinese in Australia. See IMMIGRATION RESTRICTION.

Chionanthus, a small genus of the family Oleaceae, dispersed over warm regions. Three species are indigenous to eastern Australia. *C. ramiflora* extends throughout Malaysia. Its fruit is the principal food of the jagged-tailed bowerbird. It has a dark grey mottled timber, hard and tough, yet easily worked. *C. picrophloia* is confined to Queensland, where it is known as 'Bitter-bark' (the bitter-bark of New South Wales is an *Alstonia*) and to the aborigines as 'eurpa;' its bark is intensely bitter and has been used as a febrifuge. Fabrics have been dyed with an extract from the bark in various tints of brownish-yellow.

Chip-chip. See DIAMOND-BIRDS OR PARDALOTES.

Chisholm, CAROLINE (1808-1877), born at Wootton in Northamptonshire in May 1808, was the daughter of William Jones, a well-known farmer-philanthropist of the time. In 1830 she married Archibald Chisholm, a lieutenant in the forces of the East India Company, settled with him at Madras in 1832, and with his active co-operation established there a 'school of industry' for the children of soldiers which gave them a domestic as well as a general education. In 1838 Chisholm (who had been promoted captain in 1833) obtained sick leave, and with his wife visited Hobart and Sydney, settling at Windsor in New South Wales. When her husband in 1840 was recalled to India, Mrs. Chisholm devoted herself to assisting and befriending the many young female immigrants who were at the time being 'dumped' on the shores of Port Jackson without guidance or supervision. In 1841 she appealed to Lady Gipps, and persuaded Sir G. Gipps to give her a government building for an immigrants' home; there she resided, leaving her family at Windsor, and from the home personally took parties of girls to branch homes at Campbelltown, Maitland, Liverpool, Parramatta, and Port Macquarie, settling them by degrees as servants with farmers and squatters in the various districts. The need for her work may be gauged from the facts that the first 64 girls she received into the Sydney home had 14s. 1½d. between them, and that in six years she was the means of settling 11,000 persons. On one occasion she went 300 miles inland to settle a family; on another she took 147 girls in a batch, and picked up others on her way to the west. To the home she added a registry office so efficient that only ten of the thousands of agreements made in it were ever disputed, and all ten disputes were settled. Among other activities she persuaded Robert Towns to give her 4000 acres at Shellharbour and five months' rations for the settlers she might place there; the experiment was entirely successful.

At the end of 1845 Captain Chisholm returned to Australia, and after reviewing his wife's efforts decided that, a sound organization having been established in New South Wales, immigrants could best be dealt with at the British end. In order, therefore, (*a*) to found a system of 'national colonization' and (*b*) to procure the assisted migration of families whose heads were already in Australia, the Chisholms decided to settle in England, and sailed from Sydney on 14 April 1846. Immediately on arrival in London Mrs. Chisholm opened an information office for intending migrants, founded a 'Family Colonization Loan Society,' and by sheer importunacy forced the emigration commissioners to take up the reunion of separated families. In April 1847 she gave evidence before a committee of the house of lords on the treatment of convicts. The Loan Society, however, was the most important of her creations; it was designed to encourage the migration of whole families at a time by supplementing their scanty funds so as to pay for all their passages, and incidentally effected great improvement in the conditions under which migrants voyaged. Rather than submit to the carelessness and uncleanliness of the usual shipping agents of that time, the society chartered and fitted up a model vessel, the *Slains Castle*, which in September 1850 took 250 persons to Melbourne. Other vessels followed, the movement prospered and attracted at-

tention in official circles, and in 1852 Stuart Donaldson (q.v.) carried in the New South Wales council a vote of £10,000 towards the funds of the society.

Captain Chisholm returned to Australia in 1851 to carry on the society's work at that end. Its management in London having been undertaken by Lord Shaftesbury, Sidney Herbert, and other men of their calibre, Mrs. Chisholm in 1854 joined her husband, and during 1854-5 persuaded the Victorian government to ameliorate the conditions of travel between Melbourne and the goldfields by erecting a series of rough 'dak-bungalows' along the roads. In 1857 she published in the Melbourne *Herald* a series of letters to immigrants and politicians, but towards the end of the year her health broke down, and she retired to Kyneton. In 1859 she moved to Sydney, where she delivered several lectures on migration and land legislation, but never recovered enough strength to resume her former activity. Suffering under severe strain—physical, domestic and financial—in 1862 she opened a school at Newtown, and in October 1863 removed it to Tempe, but in 1866 went back to England, was granted a civil list pension of £100 a year, and after ten years of quiet retirement died at Walham Green on 25 March 1877. Her husband died on 17 August.

The main sources of information for the more important part of this remarkable woman's life are Aeneas Mackenzie's *Memoirs of Mrs. Caroline Chisholm* (1852), and a shorter but more accurate memoir in David Mackenzie's *Emigrants Guide* (1853). Sidney's *Three Colonies of Australasia*, published in the same year, devotes a chapter to her work in New South Wales, and in Judge Therry's *Reminiscences* (pp. 416-22) there is a eulogistic account of her work, including an interesting sketch of his encounter with her while on one of her inland journeys with girls. Her own pamphlets, *Emigration and Transportation Relatively Considered* (1847), *The A.B.C. of Colonization* (1850), and *Advice to Emigrants* (1853), also throw light on her ideas. Her contemporaries admired her greatly; Michelet called her the saint of Australia, Lowe and Kendall wrote poems to her, Walter Savage Landor exalted her into a rival of Semiramis, and *Punch* dubbed her 'a second Moses, in bonnet and shawl.'

Chiton. See MOLLUSCA.

Chloanthes, a genus of the family Verbenaceae, consisting of perennials, undershrubs or shrubs, more or less cottony, woolly, or clothed with glandular hairs, all endemic in Australia. The calyx is more or less deeply divided into 5 narrow herbaceous lobes; corolla-tube elongated, usually incurved and dilated upwards, the lobes forming two lips; stamens 4, in 2 pairs, inserted below the middle of the tube above a ring of cottony hairs; fruit a dry drupe, separating into 2 hard nuts, each with a solitary seed; leaves opposite or whorled. Two eastern species, *C. glandulosa* and *C. Stoechadis* (with greenish-yellow flowers), are partial to the coastal sandstone.

Clough, White-winged (*Corcorax melanorhampus*), a rather large bird, peculiar to south-eastern Australia, usually placed in the family of crows (Corvidae). The choughs (Fregilinae) constitute a division of this family that frequents mountains and cliffs from the British Isles to northern China, extending southwards to Abyssinia and the Himalayas. If the Australian bird is really related to them, it forms a striking example of discontinuous distribution.

White-winged Chough.

The white-winged chough is a black bird with a scarlet eye, and a patch of white on the middle of the flight-feathers of the wing which is only exposed when the bird flies. It is chiefly found in the inland districts, especially near the rivers of the Murray system, where it runs about on the ground in search of insects, flying up into the trees when disturbed. Like the grey jumper and the babblers it associates in small companies, and on this account is sometimes (but wrongly) called 'apostle-bird' or 'twelve apostles;' in some districts it is also called 'black magpie' or 'mutton-bird.'

The chough builds a basin-like nest of mud, lined with grass, on the horizontal limb of a tree, and lays five to seven eggs, yellowish-white blotched all over with olive and purplish-brown. When perched in a tree it sometimes utters a low, mournful piping; and the male bird, when courting, indulges in curious antics, puffing out his feathers, spreading his wings and tail, and lowering his head.

W.B.A.

Christian, FLETCHER. See 'BOUNTY,' MUTINY OF THE.

Christmas Bells. Several species of the genus *Blandfordia* are known by this popular name, but it is usually given to *B. nobilis*, a species with rigid narrow leaves, and flowers of a wax-like texture, usually found in swampy sandstone country and confined to New South Wales. *Blandfordia*, a genus of the family Liliaceae, contains 4 species, all herbs with a thick rootstock and long tufted leaves. The erect flower-stem, rising from the centre of the tuft, bears at the top a cluster of flaming, pendulous, bell-shaped flowers shading from reddish-brown or orange to yellow. The fruit capsule is narrow, elongated and 3-angled, containing numerous seeds covered with prominent hair-like protuberances. *B. nobilis* has been described above. *B. grandiflora*, also limited to New South Wales, has larger flowers of a deeper red than *B. nobilis*. It grows in peaty pockets on the craggy escarpment of the Blue Mountains, overhanging Leura

and Wentworth Falls. *B. flammea*, with large pale flame-coloured flowers, extends from northern New South Wales to Queensland. *B. marginata*,

Blandfordia nobilis.

the handsomest of all, is limited to Tasmania, and grows even at heights of 4000 feet.

Christmas Bush, a name applied to different plants in different parts of Australia, obviously because their flowering period makes them especially suitable for Christmas decorations. The Christmas Bush of New South Wales is a *Ceratopetalum* (q.v.), *C. gummiferum*, usually a shrub, though when growing in suitable situations it attains a height of 30-40 feet. The flowers are usually in clusters, 3 in a spray; calyx-lobes 5, persistent; leaves, in opposite pairs, divided into three leaflets 1½-3 inches long, toothed round the margin, shining and feather-veined; fruit winged. The small white flowers, which have jagged petals, soon wither; then the calyx, which is at first insignificant, enlarges and turns a terra-cotta red. It is this calyx that gives the plant its highly distinctive character, its branches being widely used in New South Wales for Christmas decoration. If wounded, the shrub exudes a ruby-coloured astringent kino. The timber is fine-grained and reddish-coloured, and is sometimes used for tool-handles, etc. The shrub ranges from the Richmond River to Moruya, and as far west as the Blue Mountains; it lends itself readily to cultivation, and forms a most decorative hedge plant in suburban gardens. The Christmas Bush of Western Australia is a widely different tree, *Nuytsia floribunda* (q.v.), which, although a branching tree with a massive trunk, actually belongs to the Loranthaceae or mistletoe family. The flame-coloured masses of its brilliant orange flowers contrast strongly with the more sombre eucalypts by which it is usually

Christmas Bush.

surrounded, and justify its alternative name of blaze tree.

Chronological Table.

1606 Quiros discovers the New Hebrides. The *Duyfken* in the Gulf of Carpentaria (March). Torres sails through Torres Straits (September).
1616 Dirck Hartog discovers Eendracht Land (Western Australia).
1619 Frederik Houtman discovers western coast from Swan River northwards.
1622 The *Leeuwin* coasts south-western Australia to lat. 35° S.
1623 Jan Carstensz in the Gulf of Carpentaria. Arnhem's Land discovered.
1627 The *Gulden Zeepaert* coasts Nuyts' Land as far as Streaky Bay.
1628 The *Vyanen* runs aground on De Witt's Land.
1629 Pelsart wrecked on the Abrolhos.
1642 Tasman discovers Tasmania and New Zealand.
1644 Tasman's second Australian voyage: Australia coasted from Cape York to Eendracht Land.
1688 Dampier visits north-western Australia in the *Cygnet*, landing at Buccaneer Archipelago.
1696 Willem de Vlamingh discovers Swan River.
1699 Dampier explores north-western coast in the *Roebuck*.
1705 John Harris suggests the occupation of Tasmania.
1756 Charles de Brosses proposes that France should occupy Australasian territory with foundlings, beggars and criminals.

1766 John Callander makes similar suggestion for England.
1768 James Cook in the *Endeavour* sails for the Pacific.
1770 Cook sights the eastern coast, and annexes it under the name 'New South Wales.'
1779 Banks proposes to send convicts to Botany Bay.
1783 Matra proposes to colonize New South Wales with 'loyalists' from America.
1785 Sir George Young proposes to colonize New South Wales with 'loyalists,' Friendly Islanders and Chinese.
1786 Lord Sydney orders the equipment of a fleet to convey convicts to Botany Bay.
1787 'First Fleet' sails (May).
1788 Fleet reaches Botany Bay. Port Jackson examined and settlement made on Sydney Cove. La Pérouse in the *Astrolabe* visits Botany Bay. Norfolk Island settled.
1789 Hawkesbury River explored. Launch of first vessel built in colony. First theatrical performance in Sydney.
1790 First land grant—made to James Ruse at Rose Hill (Parramatta). First detachment of New South Wales Corps reaches Sydney.
1791 Vancouver discovers King George's Sound. Whaling and sealing industry begun. Bowen discovers Jervis Bay. Fort constructed on Dawes Point.
1792 New South Wales Corps in control of the colony. Arrival in Port Jackson of first foreign trading vessel—the *Philadelphia* from the United States.
1793 First free settlers arrive; located at Liberty Plains (Bankstown). First church built by Richard Johnson.
1794 Settlement formed at the Hawkesbury. The 'Scottish Martyrs' arrive.
1795 The Cowpastures discovered. Bass and Flinders explore George's River. First printing press erected in Sydney. Governor Hunter arrives.
1796 Bass and Flinders coast Illawarra. First theatre opened in Sydney. Coal found at Port Stephens.
1797 Coal found at Illawarra. Hunter River discovered, and coal found near its mouth. First merino sheep imported.
1798 Bass discovers Western Port. Bass and Flinders circumnavigate Tasmania.
1799 Flinders surveys coast northwards to Hervey Bay. Coal first exported (to India).
1800 Governor King arrives. Volunteer associations founded at Sydney and Parramatta. Currency regulated.
1801 Coal exported to Cape of Good Hope. Blankets and linen first manufactured in the colony. Flinders in the *Investigator* reaches Cape Leeuwin (December).
1802 Murray discovers Port Phillip (January). Flinders explores Spencer Gulf and St. Vincent Gulf (Feb.-March). Baudin on Australian coast. Flinders on eastern and northern coasts (July onwards).
1803 Bowen settles at Risdon on the Derwent, Tasmania. Collins attempts settlement on Port Phillip. *Sydney Gazette* first issued. Flinders imprisoned in the Mauritius.
1804 Paterson settles on the Tamar, Tasmania. Collins abandons Port Phillip and moves to Hobart. Abortive mutiny of Irish convicts at Castle Hill.
1805 John Macarthur, intent on developing the merino wool industry, obtains grant of 5000 acres at Camden.
1806 Hawkesbury floods. Governor Bligh arrives.
1807 First parcel of merchantable wool exported to England. Norfolk Island settlers removed to Tasmania.
1808 Bligh deposed by New South Wales Corps.
1809 First post-office opened (at Hobart).
1810 Macquarie proclaimed governor. New South Wales Corps recalled to England. First post-office on mainland opened in Sydney, and first free school established there. The *Derwent Star* (first Tasmanian newspaper) issued for a brief period.
1813 Blaxland, Lawson and Wentworth cross the Blue Mountains. Evans crosses main range and discovers Macquarie River. The 'holey dollar' circulated as currency. Evacuation of Norfolk Island completed.
1814 Civil and criminal courts separately established. First supreme court judge arrives. Hume opens up Berrima tableland.
1815 Bathurst founded. Road across the Blue Mountains completed. Lachlan River discovered by Evans. First steam-engine operated in Sydney.
1816 Sydney botanic gardens laid out. *Hobart Town Gazette* first published.
1817 Oxley explores Lachlan River. P. P. King examines north-eastern coast. Bank of New South Wales established.
1818 Meehan discovers Lake Bathurst and Goulburn Plains. Oxley explores the Macquarie, and discovers Liverpool Plains and Port Macquarie.
1819 Commissioner Bigge sent from England to report on the state of the colony. First Australian savings-bank instituted in Sydney (Campbell's Bank). Wentworth's *Statistical, Historical and Political Description of New South Wales* published in London.
1820 Wild discovers Lake George.
1821 Penal settlement established at Port Macquarie. Governor Brisbane arrives.
1822 New South Wales Agricultural Society formed. Bigge's report issued.
1823 McBrien reports discovery of gold in Fish River. Ovens and Currie explore Monaro. Oxley discovers Brisbane River; Cunningham discovers Pandora Pass. Judicature act passed. Dr. Lang arrives.
1824 Legislative council and supreme court established: trial by jury allowed on limited basis. Censorship of the press abolished. *Australian* newspaper issued. Settlement made on Melville Island. Hume and Hovell journey from Yass to Port Phillip.
1825 Moreton Bay opened up, and Norfolk Island reopened, as penal settlements. Tasmania separated from New South Wales. Van Diemen's Land Company granted 250,000 acres in north-west. Sydney chamber of commerce established. Boundary of New South Wales extended to 129° E. long. Cunningham explores Liverpool Plains. Governor Darling arrives.
1826 Settlements made at Western Port and Albany. Australian Agricultural Com-

pany granted a million acres north of Port Stephens. Australian subscription library opened in Sydney.

1827 Cunningham discovers Darling Downs. Settlement made at Raffles Bay in northern Australia. Stirling on Swan River.

1828 Western Port settlement abandoned. Richmond and Clarence River valleys opened up. Cunningham discovers track from coast to Darling Downs. Colonial (afterwards Australian) Museum founded in Sydney.

1829 Sturt discovers Darling River. Settlement made at Swan River. Settlements at Melville Island and Raffles Bay abandoned. Wakefield publishes in London *A Letter from Sydney*.

1830 Sturt discovers Murray River. Penal settlement at Port Macquarie broken up. 'Black war' in Tasmania. Perth founded.

1831 Free land grants abolished. Assisted immigration begun. First Australian steamship (*Surprise*) launched at Sydney. First steamship arrives from England. *Sydney Herald* newspaper issued. Mitchell's first expedition left Sydney. Governor Bourke arrives.

1832 Savings Bank of New South Wales established.

1833 Trial by jury extended to criminal cases. Busby made resident magistrate at Bay of Islands (N.Z.). The brothers Henty establish a whaling station at Portland Bay.

1834 Settlements formed at Twofold Bay and Portland Bay. South Australian Association organized in England. South Australia act passed.

1835 Batman and Fawkner open up Port Phillip.

1836 South Australia founded. Lonsdale made resident magistrate for Port Phillip. Mitchell discovers *Australia Felix*.

1837 Melbourne named. Adelaide founded. *South Australian Register* newspaper issued. House of commons appoints committee on transportation.

1838 George Grey discovers Glenelg River (W. A.). Settlement made at Port Essington. Assignment system restricted on mainland, preliminary to its abolition. Melbourne *Advertiser* first published. Governor Gipps arrives.

1839 New South Wales governor's jurisdiction extended to include New Zealand. New Zealand Company formed. Settlement made on Port Nicholson. Latrobe appointed superintendent at Port Phillip. Stokes discovers Port Darwin, and Eyre Lake Torrens. Strzelecki finds gold near Hartley. Camels first introduced.

1840 Hobson made lieutenant-governor of New Zealand: treaty of Waitangi concluded. Transportation to Australian mainland abolished. McMillan discovers and Strzelecki explores Gippsland. Adelaide incorporated. Perth *Inquirer* first issued. Caroline Chisholm begins her immigration work.

1841 New Zealand separated from New South Wales. Eyre's 'march' round the Bight. Clarke finds gold on Cox's River. Sydney first lit with gas. First savings-banks established at Melbourne and Adelaide.

1842 Imperial act 'for the Government of New South Wales and Van Diemen's Land' passed. Sydney and Melbourne incorporated. South Australia becomes a crown colony. Copper discovered at Kapunda (S.A.). Moreton Bay opened to free settlers.

1843 New South Wales obtains 'representative' government, Moreton Bay and Port Phillip being represented in the Sydney council. Ridley invents the stripper. Financial crisis, during which Bank of Australia fails.

1844 Sturt explores central Australia: Leichhardt starts out for Port Essington. Norfolk Island annexed to Tasmania. Port Phillip district petitions for separation from New South Wales.

1845 Sturt discovers Cooper's Creek. Leichhardt reaches Port Essington. Copper discovered at Burra Burra (S.A.).

1846 Mitchell on the Barcoo River. *Moreton Bay Courier* and Melbourne *Argus* first published. The Chisholms organize the Family Colonization Loan Society in England. Governor Fitzroy arrives.

1847 Kennedy discovers Thomson River (Q.). Leichhardt leaves Moreton Bay on his last expedition. North Australia colony established, and abandoned. Australian Agricultural Co.'s coal monopoly ceases. Overland mail between Sydney and Adelaide organized.

1848 Kennedy murdered at Escape River. Order-in-council abolishing transportation to New South Wales revoked.

1849 Indignant demonstrations in Melbourne and Sydney against revival of transportation. Port Essington abandoned. Great exodus of population to California.

1850 Transportation to Western Australia begun. Last convict ship arrives in Moreton Bay. Anti-transportation League formed in Sydney. Imperial statute 'for the Better Government of the Australian Colonies' passed. University of Sydney founded.

1851 Port Phillip district constituted the colony of Victoria. Governor of New South Wales appointed governor-general of Australia. Gold discovered in New South Wales and Victoria in payable quantities. Australian Anti-transportation League organized. First representative legislatures met in South Australia, Victoria and Tasmania. First telegraph message sent in New South Wales.

1852 Arrival of s.s. *Chusan*, first mail-steamer via Cape of Good Hope.

1853 Transportation to Norfolk Island and Tasmania abolished. Establishment of colonial mints authorized. University of Melbourne and public library of Victoria founded. Sydney corporation dissolved and a commission appointed. Cadell takes first river-steamer 1300 miles up the Murray.

1854 Eureka Stockade. First railway in Australia opened, from Melbourne to Port Melbourne.

1855 Van Diemen's Land renamed Tasmania. Responsible government proclaimed in Tasmania, Victoria and New South Wales. Chinese immigration to Victoria restricted. Sydney mint established.

1856 Government of Norfolk Island vested in New South Wales. Responsible government proclaimed in South Australia. South Australian Institute (with free

public reference library) founded. Voting by ballot introduced in Victoria and South Australia.

1857 Manhood suffrage introduced in Victoria. Sydney corporation reconstituted. Wreck of the *Dunbar*.

1858 Gregory opens up Murchison and Gascoyne districts in Western Australia. Warburton's expedition to Lake Torrens (S.A.). Telegraphic communication established between Adelaide, Melbourne, and Sydney. Manhood suffrage introduced in New South Wales. Copper discovered at Cobar (N.S.W.). Gold discovered at Canoona (Q.). Torrens act passed in South Australia.

1859 Queensland created a separate colony with responsible government. Brisbane incorporated.

1860 McDouall Stuart reaches centre of Australia. Burke and Wills set out for Gulf of Carpentaria.

1861 Title of governor-general abolished. F. Gregory discovers Fortescue, Ashburton, and De Grey Rivers (W.A.). New South Wales territory between 129° and 132° E. long. and south of 26° S. lat. added to South Australia. Anti-Chinese riots at Lambing Flat (N.S.W.). First Melbourne Cup run. Western boundary of Queensland shifted to 138° E. long. Death of Burke and Wills.

1862 J. McKinlay reaches Albert River from Adelaide. McDouall Stuart reaches Chalmers Bay from Adelaide. Kendall's *Poems and Songs* published. First English cricket team visits Australia.

1863 Intercolonial conference held in Sydney. Northern Territory placed under jurisdiction of South Australia. Kanaka labour introduced into Queensland.

1864 First manufacture of sugar (in Queensland). Kanakas employed for sugar cultivation. English salmon ova placed in Plenty River (Tasmania).

1867 Intercolonial conference held, at which Parkes suggests a confederate union. First Victorian protective tariff in operation. Gold discovered at Gympie (Q.). Publication of Gordon's *Sea Spray and Smoke Drift*. Duke of Edinburgh visits Australia.

1868 Transportation to Western Australia discontinued. Kanaka labourers act passed in Queensland.

1869 Electric cable laid between Cape Schanck (Vic.) and Low Head (Tas.). Sydney free public library opened. Kendall's *Leaves from Australian Forests* published.

1870 Intercolonial conference held to discuss intercolonial free trade. British troops withdrawn from Australia. Nominee legislative council of Western Australia dissolved and a partly elective council substituted. Palmerston made capital of Northern Territory. John Forrest leads overland expedition from Western Australia to Adelaide. Gordon's *Bush Ballads* published.

1871 Tin discovered at Mount Bischoff (Tas.). Submarine cable laid between Port Darwin and Banjoewangie (Java). Primary education made compulsory in Western Australia.

1872 Polynesian protection act passed by British parliament. Overland telegraph line from Adelaide to Darwin completed. First through cable message received from England. Melbourne mint opened. Gold discovered at Charters Towers (Q.).

1873 Intercolonial conference favours customs union. Free, compulsory and secular education established in Victoria.

1874 Expedition of J. and A. Forrest from the Murchison to the overland telegraph line. Triennial parliaments act passed in New South Wales. University of Adelaide founded. Clarke's *For the Term of his Natural Life* published in book-form.

1875 Giles leads expedition from overland telegraph line to western coast. Free and compulsory primary education established in Queensland. Compulsory primary education provided for in South Australia. Influx of Chinese to the Palmer goldfield (Q.).

1876 Death of Truganini, last of the Tasmanian aborigines.

1877 Overland telegraph line from Adelaide to Perth completed. Chinese immigration to Queensland restricted. First test match (England-Australia) played in Melbourne.

1878 Seamen strike against coloured labour. 'Black Wednesday' in Victoria. Payment of members act passed in Victoria.

1879 A. Forrest discovers Fitzroy pastoral country (W.A.). First intercolonial trade unions congress held. First artesian bore in Australia sunk in New South Wales. First steam tramway opened in Sydney.

1880 Intercolonial conference in Melbourne. Australian frozen meat first delivered in London. Primary education made compulsory in New South Wales. Art Gallery of New South Wales opened. Kendall's *Songs from the Mountains* published.

1881 Intercolonial conference continued in Sydney. Parkes proposes a federal council. Chinese restriction acts passed in New South Wales, Victoria, and South Australia. First simultaneous census taken in Australia.

1882 Gold discovered at Mount Morgan (Q.).

1883 Queensland annexes south-eastern part of New Guinea. Silver discovered at Broken Hill. Through railway traffic established between Melbourne and Sydney.

1884 British protectorate over south-eastern New Guinea declared. Public library, museum, and art gallery of South Australia established.

1885 Federal council created. Sudan contingent sails. Broken Hill Proprietary Co. commences operations. Silver-lead discovered at Mount Zeehan (Tas.), and gold in the Kimberley district (W.A.).

1886 Federal council first meets.

1887 Colonial conference held in London. First naval defence agreement made. Gold discovered at Yilgarn (W.A.). Public library, museum and art gallery of Western Australia established. First express train runs between Adelaide and Melbourne.

1888 Intercolonial conference considers Chinese immigration; restrictions increased. Australasian Association for the Advancement of Science holds first meeting. Rolf Boldrewood's *Robbery under Arms* published. Tamworth (N.S.W.) lighted with

electricity—first Australian town to adopt this system. Centenary celebrations at Sydney.

1889 Hawkesbury River bridge (N.S.W.) completed. University of Tasmania founded. Lawrence Hargrave discovers principle of rotary engine.

1890 Responsible government established in Western Australia. Maritime strike.

1891 First federal convention drafts federal constitution. Colonies enter Universal Postal Union. First labour party in Australia appears in New South Wales parliament. Free primary education introduced in South Australia.

1892 Rich gold reefs found at Coolgardie (W.A.).

1893 Financial crisis. 'One man one vote' electoral act in force in New South Wales. 'New Australia' party leaves for Paraguay.

1894 Colonial conference meets at Ottawa. Women enfranchised in South Australia. Hargrave makes successful experiments with box-kites.

1895 Intercolonial conference of premiers held. Anglo-Japanese treaty rejected by all the colonies except Queensland. Paterson's *Man from Snowy River* published.

1896 Wages boards established in Victoria. Publication of Lawson's *In the Days when the World was Wide* and *While the Billy Boils*. Brisbane (now Queensland) public library established. Death of Sir H. Parkes.

1897 Colonial conference in London. Second federal convention meets.

1898 Federal constitution bill rejected at referendum in New South Wales. W. J. Farrer appointed official wheat experimentalist. Daley's *At Dawn and Dusk* published. David Scott Mitchell offers his library to the N.S.W. government.

1899 Amended federal constitution bill accepted by New South Wales, Victoria, Queensland, South Australia and Tasmania. Free primary education introduced in Western Australia. Australian troops take part in South African war.

1900 Commonwealth bill passed by Imperial parliament. Western Australia accepts federal constitution. Edmund Barton forms first federal ministry. Australian troops, with gunboat *Protector*, take part in Boxer war (China).

1901 Commonwealth of Australia proclaimed. First federal parliament opened in Melbourne. Inter-State free trade established. White Australia policy embodied in federal acts. Victoria and New South Wales make provision for old age pensions. Industrial arbitration act passed in New South Wales.

1902 Colonial conference in London. Second naval defence agreement made.

1903 Federal high court established. Coolgardie and Kalgoorlie water-supply scheme completed.

1904 First federal labour ministry. Federal conciliation and arbitration act passed. Importation of Kanakas to Queensland discontinued.

1905 Contract immigrants act passed.

1906 Papua taken over by Commonwealth. Primary education made free in New South Wales.

1907 Imperial conference in London.

1908 First *Commonwealth Year Book* issued. Yass-Canberra chosen as site of federal capital. Queensland makes provision for old age pensions. Primary education made free in Tasmania.

1909 Imperial defence conference held in London. Australian defence act, providing for compulsory military training, passed. Visit of Lord Kitchener to advise on Commonwealth military defence. Office of Australian high commissioner in London created. Federal act providing for the payment of old age pensions throughout Australia in operation. First successful aerial flight in a power-driven machine took place. University of Queensland founded.

1910 Referendum on financial relations between Commonwealth and States. Penny postage introduced. First vessels of Royal Australian Navy arrive. Admiral Sir R. Henderson visits Australia to advise on naval defence. First federal bank-notes issued. Visit of Scottish agricultural commissioners.

1911 Imperial conference in London. Temporary committee of Imperial defence formed. Admiral Henderson's naval report. Commonwealth takes over Northern Territory from South Australia. First federal census. University of Western Australia founded. Compulsory military training established.

1912 Commonwealth Bank established.

1913 H.M.A.S. *Australia* arrives. Federal capital city founded and named Canberra.

1914 General Sir Ian Hamilton reports on Australian military defence. Visit of British Association for the Advancement of Science. European war. Australian expeditionary force occupies German New Guinea. H.M.A.S. *Sydney* destroys German warship *Emden*.

1915 Australian troops landed on Gallipoli peninsula (25 April). Broken Hill Proprietary Co.'s steelworks at Newcastle opened.

1916 Australian troops in France. First conscription referendum held.

1917 First Imperial war cabinet formed. Federal national ministry formed. Second conscription referendum held. General strike in New South Wales. Trans-Australian (east-west) railway completed.

1918 Australia House, London, opened.

1919 Australia admitted to League of Nations. Seamen's strike and Broken Hill strike. Commonwealth competition aerial flight, England to Australia, won by Ross and Keith Smith.

1920 Visit of the Prince of Wales.

1921 Imperial conference in London. Australia takes over German New Guinea as a mandatory under League of Nations. Federal government takes over control of immigration machinery in London.

1922 Legislative council of Queensland abolished. Geraldton-Derby (W.A.) and Charleville-Cloncurry (Q.) aerial mail services in operation.

1923 Imperial conference and Imperial economic conference held in London.

1924 Adelaide-Sydney aerial mail service in operation.

Church of England. In 1786 Viscount Sydney, among other arrangements for the welfare of the proposed settlement in New South Wales, provided for the appointment of a chaplain at a salary of £182 10s per annum. After consulting William Wilberforce (who in turn consulted others, including John Newton of Olney and Cowper the poet), he found that a student, one Richard Johnson (q.v.), who was ready to take holy orders, would be willing to accept the position of chaplain at Botany Bay. Johnson was ordained, and on 10 October 1786 commenced his duties by visiting the hulks and making preparation for the voyage; he received his commission on 24 October. The First Fleet, with Johnson in the store-ship *Golden Grove*, reached New South Wales in January 1788, and on 3 February (the second Sunday after landing) the first religious service was held 'under a great tree' in the presence of the troops and convicts, whose behaviour on this occasion was equally regular and attentive. The site of that service must have been somewhere near, if not actually in, the present Macquarie Place. Johnson's first desire was to erect a suitable building wherein to hold his services, and he sought the governor's aid; but, in spite of explicit instructions (issued on 20 August 1789 to Phillip) that 'a particular spot in or as near each town as possible be set apart for the building of a church, and four hundred acres adjacent thereto allotted for the maintenance of a minister, and two hundred for a school-master,' the building of a church was the last thing that seemed to trouble the governor and his officials. It was not till 1793 that the colony had a definite meeting-place for worship. In the meantime Johnson's duties were practically doubled by the founding of another settlement at Rose Hill (Parramatta), and he complained to the governor in writing both about the lack of a church and about the hardship of having to minister at both Sydney and Rose Hill. In September 1791, however, a detachment of the New South Wales Corps arrived and was stationed at Rose Hill, and the regimental chaplain (James Bain) took over most of the duties at this settlement, leaving Johnson to attend to Sydney. Norfolk Island being a part of the new colony, it was the chaplain's duty to make an occasional visit there, but the inconvenience of this arrangement caused Lieutenant-governor King to apply for an assistant to work on the island; John Crowther was appointed, and left England in September 1789 in the ill-fated *Guardian*, which struck an iceberg after leaving the Cape of Good Hope. The passengers reached the Cape in the ship's boats, and Crowther, disheartened by this experience, threw up his appointment and returned to England.

Johnson, finding all complaints futile, now began to build a temporary church on the east side of the Cove, about the corner of Bligh- and Hunter-streets. Begun on 10 June 1793, it was ready for its first service on 25 August. The design was cruciform, the nave being 75 feet long by 15 broad, and the transepts 40 feet by 15 feet; it was built of wattle and dab, and the roof was thatched. It provided seating accommodation for 500 persons and cost in all £67 12s. 11½d., of which £59 18s. 6d. was paid in Spanish dollars and the rest in provisions and spirits. Johnson in a letter to Henry Dundas (dated 3 September 1793) gave full particulars, and asked that the money should be refunded; but it was not till 31 January 1797 that the authorities admitted the justice of his claim. On 19 March 1925 was laid the foundation-stone of a memorial marking the site of this church; it also commemorates the holding of the first service in February 1788, but that service—as has been said—was held under a tree much nearer the Cove.

Crowther having abandoned his duties, it became necessary to find another assistant for Johnson, and Samuel Marsden (q.v.), a student of St. John's College, Cambridge, was offered the position. Marsden at first refused the offer, but changed his mind and accepted it; his commission was dated 1 January 1793, and shortly afterwards he was ordained. Leaving England on 1 July 1793 in the ship *William*, he reached Sydney on 10 March 1794. As there were now three clergymen in the colony, Johnson retained the Sydney work, and Marsden and Bain were stationed at Parramatta, the duties there becoming more arduous as the population grew. Johnson and Marsden took it in turns to visit Norfolk Island. But settlement began to extend; in 1794 the Hawkesbury valley was settled, and round Parramatta grew up the villages of Prospect, Toongabbie and Castle Hill, all three requiring periodical visits. Again the work was expanding beyond the strength of the chaplains, and, to add to it, on 15 December 1794 James Bain left the colony, and Marsden had to take over the military chaplainship. In September 1796 he opened at Parramatta a temporary chapel, built from material obtained by pulling down two huts, and this structure served its purpose till a permanent building could be erected. The foundation of such a building was laid on 5 April 1797, and it was called 'St. John's' after Governor Hunter, who had assisted the chaplains in every way since his arrival in September 1795. On 1 October 1798 Johnson's temporary church at Sydney was burnt down in circumstances that showed that the burning was wilful. Hunter then granted Johnson the use of a store on the east side of the Cove, near the present customs-house, and services were held there on the following Sunday. On 7 October Hunter laid the foundation-stone of a new church on Church Hill.

In May 1798 there arrived in Sydney a number of missionaries from Tahiti, who had been sent there in the ship *Duff* some time previously, but, fearing massacre, had sought shelter in the brig *Nautilus*, a trader from Sydney. Hunter permitted them to settle in the colony. Among them was Rowland Hassall, who was enlisted as a catechist and sent to Parramatta to assist Marsden. Hassall at once interested himself in the religious needs of Kissing Point (now Ryde) on the Parramatta River, obtained subscriptions from the settlers, and built there a church which was opened on 16 July 1800 by the two chaplains. The church building was used as a schoolroom during the week, and the governor appointed Matthew Hughes (afterwards well-known as schoolmaster and parish clerk at Richmond) to be schoolmaster. The records show that 20 scholars attended the school from its inception.

At this stage Johnson, who had applied to the colonial office for leave of absence owing to failing health, left the colony with Hunter in H.M.S. *Buffalo*. This made Marsden the only official chaplain in the colony, with one catechist to assist him. Marsden immediately arranged to undertake all the duties, enduring much fatigue and hardship in the performance of them; he regularly served Parramatta and Sydney, and visited the other settlements whenever opportunity presented itself. In the mean-

That the above is to the best of my knowledge a just Estimate of the Expences in erecting the above Building I am willing to be upon oath if at any time or by any Person I am required —

Sydney Sep^r 30^th 1793 —

Richard Johnson Chaplain

Johnson's Statement of Moneys Expended for the First Church.

time he pushed on with the building of St. John's at Parramatta, and opened it on Easter Sunday, 10 April 1803. The church was described as the best public building in the colony; it was 100 feet long by 44 feet wide, and attached to it was a room 20 feet long raised on stone pillars for use as a vestry.

On 23 July 1802 Governor King divided the colony into two parishes. The order stated 'that in all Spiritual, Judicial, and Parochial Proceedings, Transactions, Deeds, Instruments, and Registers, that the Districts of Sydney, Petersham, Bulanaming, Concord, and Liberty Plains, be comprised with a Parish to be henceforward named "Saint Phillip," in honor of the first Governor of this Territory; and that the Districts of Parramatta, Banks' Town, Prospect Hill, Toongabbie, Seven Hills, Castle Hill, Eastern Farms, Field of Mars, Northern Boundaries, Ponds, and Kissing Point, be comprised with a Parish to be henceforward named "St. John's," in honor of the late Governor, Captain John Hunter; and that the Churches now building at Sydney and Parramatta be respectively named Saint Phillip and Saint John.' On 1 March King had complained to the colonial office that there was only one clergyman in the colony to do the work, and asked (without success) that an appointment should be made. It being impossible for Marsden to visit Norfolk Island, King took it upon himself to appoint a clergyman, one Henry Fulton (q.v.), who had arrived on 11 January 1800 with a number of convicts from Ireland. Fulton had been deported for sympathizing with those concerned in the rebellion of 1798. The colonial office approved of the appointment, and authorized the payment of Fulton's salary £96 per annum.

In 1804 Pascoe Crook (q.v.) one of the Tahiti missionaries already referred to, who had not come to Sydney but had returned to England, arrived in the colony in the store-ship *Ocean*. He was at once appointed schoolmaster at Parramatta and catechist to assist Marsden in the outlying settlements. On 1 March 1804 King again called the attention of the colonial office to the fact that there was only one chaplain in the colony, adding that he had appointed three catechists 'with their families to be victualled and receive other indulgencies as a recompence for their reading prayers and preaching every Sunday at those settlements that the Rev'd Mr. Marsden cannot attend.' The three were Hassall at Kissing Point, Crook at Parramatta, and Harris (another missionary from Tahiti) at the Hawkesbury. For Harris King erected a building to serve as a church on Sundays, a schoolhouse during the week, and a residence for the schoolmaster as well, Harris acting as schoolmaster in 1805-8. In a summary of the state of the colony made by King (apparently for Bligh's use) on 12 August 1806 the situation with regard to chaplains is thus described:—'Since Mr. Johnson's resignation in 1801, that duty has been performed by the Rev. Mr. Marsden with much assiduity and zeal. A church is built at Parramatta, and one of stone is far advanced at Sydney, the first of which has obtained the name of St. John, and the latter that of St. Phillip. Exclusive of Divine service being performed each Sunday at those settlements, two missionaries of good character perform Divine service at Hawkesbury, Castle Hill, and Kissing Point, with great advantage to the inhabitants. After a residence of thirteen years, Mr. Marsden has obtained my leave to go to England on account of indisposition and to arrange his private concerns; and that the important duties of religion may not be neglected, the Rev. Mr. Fulton, chaplain of Norfolk Island, does Mr. Marsden's duty in these settlements during his intended absence.' Marsden sailed in H.M.S. *Buffalo* on 10 February 1807, and Fulton was left in sole charge. Bligh, who thought him 'a moral, good man,' pointed out in a despatch of 7 February 1807 that the colonial office must either confirm Fulton's appointment or at once send out more chaplains. The appointment was not confirmed until 31 May 1811, and in the meanwhile Marsden—who was on the look-out for assistants from the moment he reached England—had secured the services of William Cowper and Robert Cartwright. Before, however, they could reach Sydney the New South Wales Corps had deposed Bligh, suspended Fulton for sympathizing with him, and put Crook in his place as principal chaplain. Cowper, who reached Sydney in advance of Marsden on 18 August 1809, was on the 22nd appointed assistant chaplain.

On 1 January 1810 Lachlan Macquarie assumed the governorship, and at once reinstated Fulton. On 27 February Marsden and Cartwright arrived, and the situation became normal again, Marsden taking Parramatta, Cowper the Sydney parish (St. Philip's), and Cartwright the Hawkesbury. Fulton went to England with Bligh, who required him as a witness. Macquarie, who had a stern sense of religious duty, aided the chaplains greatly. The lax observance of the Sabbath shocked him: he ordered that all convicts in government employ, and all ticket-of-leave men, should be mustered every Sunday morning and marched to church at one of the three settlements. He also established a scale of fees for marriages, christenings and funerals, and insisted that registers should be kept. Before the end of his first year of office he had completed the building of St. Philip's church, the name of which he altered to conform to the recognized spelling of the real saint's name. The foundation-stone of this church was (as has been already mentioned) laid in 1798; a large clock for the tower had been sent out in 1797, and temporarily erected on the slope of Church Hill; a peal of eight bells cast in 1794 by T. Mears of London, and brought out by Governor Hunter, was hung in the church tower on 29 May 1807. This peal was afterwards distributed, three bells only being retained; it is probable that five were sold by auction in 1833, as an advertisement of that year includes 'Church Bells' among obsolete government stores for sale—but the authority for this action cannot be traced. The three that remained disappeared when the old church was demolished in 1856, but have in recent years been rediscovered—one in 1885 at a Church of England school in Randwick (a suburb of Sydney), one in 1911 in use on the lightship *Bramble* in Port Jackson, and a third in 1917 at Bourke gaol. In 1804 George III presented the colony with a fine service of Communion plate, which was kept for use in St. Philip's; tablets setting forth the Creed and the Ten Commandments were also sent from England, but the building which was to house them was long in construction. Macquarie hastened the opening, which took place on 25 December 1810.

In 1812 Fulton returned from England with a commission as assistant chaplain, and was appointed to St. Philip's to assist Cowper. In 1814 he was transferred to the Hawkesbury (by then divided into the parishes of Castlereagh and Richmond) and served there till his

death. In 1816 John Youl, who had succeeded Harris as catechist at the Hawkesbury and had afterwards gone to England to be ordained, returned to Sydney with a commission appointing him assistant-chaplain at Port Dalrymple; on his arrival, however, Macquarie sent him to Liverpool until proper accommodation could be provided for him at Launceston. In 1819 this condition was fulfilled, and Youl took up his duties at Launceston in November. Both Hassall and Youl held services in the Ebenezer chapel at the Hawkesbury, which, though erected primarily for Presbyterian services, soon became a 'mixed community chapel.'

Meanwhile Marsden was becoming restive. The bounds of settlement were extending widely and the population increasing with great rapidity, yet no extra assistance could be procured from England. He urged on Macquarie again and again that applications by letter to the authorities in London were useless, and that only the presence in England of someone able to give full information about Australian conditions could avail to procure the requisite help. Macquarie, unfortunately, was convinced that Marsden wanted to go to England only in order to join Jeffery Bent in attacking his administration, and refused to let the senior chaplain leave the colony. In May 1818 he sent the colonial office an urgent despatch on the need of more chaplains, and in December relief was at last given.

On 18 June 1819 Richard Hill arrived in the *Hibernia*, and was appointed to assist Cowper, whose duties were ever increasing. Eight days later John Cross arrived, and was stationed at Windsor; Cartwright was sent to Liverpool, thus leaving Youl free to proceed to Launceston. B. Vale, who also came out about this time, quarrelled with the governor and returned after a stay of a few months. In 1822 Hassall, who had gone to England to be ordained, returned and went to Parramatta to assist Marsden; later he was appointed to St. Paul's, Cobbitty, from which centre he served the area extending to Goulburn on the south, Wollongong on the coast, and Mulgoa westwards. In January 1820 George A. Middleton arrived, and in September Thomas Reddall; the former went to Newcastle and the latter to Campbelltown. By this time Sydney had grown so large that it was decided to divide it into two parishes, St. Philip's on the west side and St. James's on the east. On 7 October 1819 Macquarie laid the foundations of the new parish church, which was consecrated on 11 February 1824. Churches were also built or begun in Macquarie's time at Windsor (1820), Liverpool (1819), Campbelltown, and Newcastle, and he ordered the erection of a church at Port Macquarie which was begun in December 1824, with Hassall as chaplain to the settlement. The Liverpool church (St. Luke's) is claimed to be the oldest Anglican church now existing in Australia; it has lost its Macquarie portico, but retains over its entrance door the inscription that records its erection in 1819. It was completed in 1824; Robert Cartwright was its first incumbent.

At the foundation of the colony there was no Church authority extant, except that by an order-in-council of Charles I all British subjects outside Britain were under the jurisdiction of the bishop of London. The chaplains were civilian or military officials performing spiritual functions. But technically Australia and Tasmania were within the limits of the East India Company's charter of 31 December 1600; and when in May 1814 a bishopric of Calcutta was created it was expressedly stated to include all British territory within those limits, and so brought Australia and Tasmania for the first time under episcopal jurisdiction. When in 1824 New South Wales attained a certain degree of self-government by the grant of a legislative council, the ecclesiastical position also was regularized; in May the jurisdiction of the bishop of Calcutta was formally reaffirmed, and on 2 October the colony was constituted an archdeaconry of the Calcutta diocese, Thomas Hobbes Scott (q.v.) being appointed the first archdeacon. He reached Sydney on 7 May 1825, and at once entered on the work of organizing his clergy. Simultaneously with his appointment the colonial office drafted a scheme for setting aside lands in the several counties—to comprise 'one seventh part in extent and value of all the lands in each County'—from whose revenues should be obtained 'an adequate provision for the support of the Clergy of the Established Church of England throughout the colony, and for the Education of Youth in the principles of the Church.' These lands were to be administered by a corporation of officials, with the governor and archdeacon at their head, to be known as 'The Trustees of the Clergy and School Lands.' The mere existence, however, of this body created such an outcry among supporters of other denominations—notably the Roman Catholics and Presbyterians—that in 1829 the colonial office decided to abolish the trust, which had been allotted its first estates (amounting to 393,283 acres in all) only in February of that year. The usual delays followed. On 19 June 1830 formal instructions were issued to Darling to substitute for the trust a commission of five members; on 14 February 1831 the order to reserve lands in the several counties was cancelled; legal objections raised in the colony kept the trust intact a year or two longer; but on 4 February 1833 an order-in-council explicitly dissolved it, and in 1834 an act of the New South Wales legislative council provided for the future management of the church and school estates, which were resumed by the crown. To make up for the loss of revenue to the ecclesiastical establishments a sum of £30,000 was voted annually, to be divided between the Anglican, Roman Catholic, Presbyterian, and Wesleyan bodies. This grant was reduced to £28,000 on 1 July 1851, when Victoria became a separate colony.

The first service west of the Blue Mountains was conducted in the public granary at Bathurst on 13 October 1822 by Samuel Marsden, whose son-in-law Thomas Hassall (son of Rowland Hassall already mentioned) was appointed to the parish of Bathurst in 1826. The parish extended from Hartley westwards to Boree (beyond Orange) and south-west to Carcoar. Hassall established temporary chapels at Kelso and O'Connell, but in 1827 was transferred to Camden and succeeded by John Espy Keane. Holy Trinity church at Kelso was opened by Samuel Marsden in 1835, and consecrated by Bishop Broughton on 3 December 1836. In 1840 a minister was appointed to the 'parish church of All Saints at Bathurst,' but the foundation-stone of this church was not laid until 24 January 1845, and services were first held in it in 1848. It was consecrated on 14 December 1849. On 6 May 1870 it became the cathedral church of the Bathurst diocese.

Reverting to the affairs of the Church as a whole, Archdeacon Scott resigned in 1828, and William Grant Broughton (q.v.) was chosen on 7 December of that year to succeed him.

Broughton arrived in the colony on 13 September 1829 and was sworn in by the governor on the 17th. The Church was progressing *pari passu* with the colony, but the clergy were enduring many hardships. Archdeacon Scott in 1829 stated that their families were often 'obliged to forego the use of meat and flour and subsist on a less substantial diet.' Cartwright out of a salary of £250 per annum spent, one year, £150 in maintaining a horse for his parochial duties. One of the few compensations was the grant of 1250 acres of land regularly made by the colonial government to a clergyman's daughter on her marriage.

By 1833 there were 15 clergymen in the archdeaconry, and separation from Calcutta became advisable. In 1834, therefore, Archdeacon Broughton proceeded to England, and after consultation with the home authorities it was decided to raise the colony to the dignity of a separate see. This was done on 18 January 1836, William Grant Broughton being appointed the first bishop; the see was to be subordinate to Canterbury, and was endowed with a sum of £3000. King William IV presented two services of Communion plate for diocesan use. By this time the population of Sydney had grown to 20,000; a new parish (St. Lawrence) was therefore formed, and services were held in a temporary building while Christ Church was being built. When Bishop Broughton on 2 June 1836 returned to Sydney, he set to work to organize the new diocese thoroughly. In November he requisitioned the government for at least nine more clergy. Appeals for funds to build churches, schools, and vicarages were readily answered by the English Church Society and the colonists, and in 1837 the bishop was able to report that £13,000 had been raised locally (for the most part in small amounts) and £4000 had been sent from England. The diocese, however, was already becoming too unwieldy. Tasmania was a long journey from Sydney; new centres were being opened up as far north as Moreton Bay; Port Phillip was growing rapidly, and at Adelaide another settlement had been made, so that it became impossible for the bishop to visit the various areas of his great see with any degree of regularity. The first step towards a division of the see was taken on 18 August 1842, when Tasmania was made a separate diocese. A little later it was decided to divide the mainland into four sees —Sydney, to include all the southern portion of New South Wales; Newcastle, all the northern portion, including the Moreton Bay district; Melbourne, to include all the Port Phillip district; and Adelaide, to include South and Western Australia. This division was made possible by help from the colonial bishoprics fund and by the munificent gifts, especially to Adelaide, of Angela Burdett-Coutts. By 25 June 1847 all that was wanted was a bishop for each diocese, and on the 29th the three new bishops were consecrated in Westminster Abbey, William Tyrrell for Newcastle, Charles Perry for Melbourne, and Augustus Short for Adelaide. Bishop Broughton was made bishop of Sydney and metropolitan of Australia. All these sees have since been much subdivided: the several dioceses are dealt with below under the names of the States in which they are situated, and many important events in their history are narrated under the names of the bishops most closely connected with them.

New South Wales.—Bishop Broughton died in 1853 while on a visit to England, and William Cowper (by this time an archdeacon) administered the diocese of Sydney pending the appointment of a successor from England. On 30 November 1854 Frederick Barker, vicar of Baslow in Derbyshire, was consecrated bishop; he reached Sydney on 25 May 1855, and was installed on the 31st.

The discovery of gold brought a great influx of population, and the difficulty of obtaining clergymen from overseas caused the authorities to establish a training-school in the colony; in this they were materially assisted by the will of Thomas Moore of Moorebank near Liverpool in New South Wales. In 1840 Moore had left all his property to the Church, and assigned Moorebank as a college for the education of youths between the ages of 16 and 23 in accordance with the doctrines of the Church of England. By 1856 the income had so far increased that Bishop Barker was able to establish a college with William Hodgson, of Sidney Sussex College, Cambridge, as principal. Bishop Broughton had previously established a college at Lyndhurst House in the Glebe (a suburb of Sydney) with Robert Allwood as principal; both secular and divinity students were trained there, but the venture failed for lack of support. Hodgson did not arrive till August 1856, and William M. Cowper (afterwards Dean Cowper) took up his residence at Moorebank as temporary principal. When Hodgson did arrive, the trustees decided to build a chapel, hall, library, and rooms for students. The parish of Holdsworthy was placed under the charge of the principal, and the students were detailed to take services and assist the rector of Parramatta in the outlying portions of his parish. On 17 December 1857 the college chapel was opened and licensed as Broughton Chapel (in memory of the late bishop); an appeal to the community supplied the remainder of the money, and the college was opened free of debt. Bishop Barker while in England also appealed for funds, and a sum of £4000 was subscribed. In 1868 Hodgson resigned, and Robert Lethbridge King was appointed; when he resigned in 1887 the vice-principal, George Sheppard, directed the work until A. L. Williams arrived in August 1888. In 1889 the college was moved from Liverpool to new buildings near the university of Sydney. Its heads have been T. E. Hill (1889), B. A. Schleicher (1891-97), Nathaniel Jones (1897-1911) and David John Davies.

Bishop Barker hastened the completion of St. Andrew's cathedral at Sydney. This church was originally planned by Governor Macquarie to provide additional accommodation for the Anglicans of his time, the 'Old Church' of St. Philip's becoming overcrowded by about 1818. In 1819 Macquarie laid the foundation-stone of 'an intended Church on a large scale in the Center of the Town (at the junction of "George Street" and "Bathurst Street")'—a site which he had marked out as far back as 1812; but Bigge insisted on the abandonment of this scheme, and provided the necessary accommodation by converting Macquarie's half-built court-house into St. James's church. On 16 March 1837 Governor Bourke laid a new foundation-stone on the George-street site, and efforts were made spasmodically to erect a suitable cathedral building; but lack of funds and the abnormal labour conditions of the gold-rush period hampered the work so that little progress was made until Barker's time. The cathedral was completed and opened on St. Andrew's day, 30 November 1868. The western towers were added in 1874, and the chapter house (as a memorial to the bishop) in 1886. In 1856 Barker also founded

the Church Society, which since the abolition of state aid has been the chief instrument in the creation of new parishes in the diocese. In 1872 it was decided that on two Sundays in the year the whole of all church collections within the diocese should be devoted to the funds of the Church Society. Under the name 'home mission fund' bodies of this nature operate in every diocese in Australia.

Synods were instituted during this period for the regular working of the diocese. In 1866 an act of parliament enabled the Church to manage its own property. On 5 December of the same year the Sydney diocesan synod was first called together, and it has since met annually. Out of this synod grew the synod of the province, to which clerical and lay representatives from every diocese are elected. The provincial synod receives appeals from diocesan synods against the vote of the bishop, and legislates on any matter referred to it by any diocesan synod. The first provincial synod met on 11 May 1869. In 1872 a general synod of the Anglican Church in Australia was formed to deal with matters sent up from provincial synods, and to legislate for the appointment or trial of bishops; but any determination of general synod must be adopted by a diocesan synod before it becomes law in the diocese. General synod meets every fifth year, and is presided over by the primate; in the absence of a primate, in accordance with decrees made by general synod in 1900, the house of bishops elects one of the metropolitan bishops to act in his place. A new constitution was framed in the Church of England constitution act of 1902.

During Barker's episcopate the southern portion of the see of Sydney was (on 14 March 1863) formed into the diocese of Goulburn, with Mesac Thomas as bishop. The western portion was proclaimed the diocese of Bathurst in 1869, S. E. Marsden (grandson of Samuel) being made bishop, and installed on 5 May 1870. On 6 April 1882 Bishop Barker died, and was succeeded by Alfred Barry on 24 April 1884. Dr. Barry resigned in 1889, and his successor, William Saumarez Smith, took office in the following year. In 1897, during his occupancy of the see, the diocese was raised to the dignity of an archbishopric by resolution of general synod. Dr. Smith died on 18 April 1909, and was succeeded by John Charles Wright who was consecrated on 24 August 1909. All except the last-named held the position of primate and metropolitan of Australia by virtue of their office as bishop or archbishop of Sydney; Dr. Wright was elected by the bishops of Australia.

During the episcopate of Bishop Tyrrell the Newcastle diocese was in 1859 relieved of the charge of the Brisbane district, and was again diminished in 1869 by the formation of the diocese of Grafton and Armidale. Tyrrell died on 24 March 1879, and Josiah B. Pearson took his place; he resigned in 1889, and was succeeded in 1891 by George Henry Stanton, who was translated from the diocese of North Queensland. In 1906 John Francis Stretch was appointed to the see; he was succeeded in 1919 by Reginald Stephen, who was translated from Tasmania. On 24 February 1869 James Francis Turner was consecrated bishop of the new diocese of Grafton and Armidale; he was succeeded in 1901 by H. E. Cooper, who had been coadjutor at Ballarat since 1895. In 1914 the diocese was again divided, Grafton being separated under Cecil Druitt, who since 1911 had been coadjutor in the undivided diocese. Bishop Cooper was succeeded at Armidale in 1916 by W. F. Wentworth-Shields, and Bishop Druitt at Grafton in 1921 by John William Ashton. At Bathurst Bishop Marsden held office until 1885, and was succeeded in 1887 by Charles Edward Camidge. On 30 November 1911 George Merrick Long took over the diocese, and is still (1925) in office. In 1884, during the episcopate of Mesac Thomas, the diocese of Goulburn was diminished by the formation of the diocese of Riverina under Dr. Sydney Linton. Dr. Thomas was succeeded in 1892 by William Chalmers. In 1902 Christopher George Barlow was translated to the see from North Queensland; he was succeeded in 1915 by Lewis B. Radford, the present bishop. Bishop Linton of Riverina was succeeded in 1895 by Ernest Augustus Anderson, who resigned at the end of 1924.

Tasmania.—On 27 January 1804 Lieutenant-governor David Collins founded a settlement at Hobart. Robert Knopwood (q.v.), his chaplain, conducted the first services in a tent, pending the erection of a church. At Port Dalrymple Lieutenant-governor Paterson appointed one Edward Main of H.M.S. *Buffalo* to look after the spiritual welfare of the place. On 19 February 1816 was laid the foundation-stone of the first church in Hobart, which was named 'St. David's' in honour of Lieutenant-governor David Collins. Youl took up his duties at Launceston in November 1818, and in 1822 W. Bedford was appointed chaplain at Hobart. Knopwood retired on 27 April 1823, and died on 8 November 1836. On 28 December 1824 the foundation-stone of St. John's at Launceston was laid, and 12 months later the church was fit for divine service. In this year (1825) Samuel Marsden consecrated St. David's at Hobart. Bedford, supported by Governor Arthur, pushed on with every branch of his work, and progress became rapid. The next governor, Sir John Franklin, was an ardent churchman, and during his regime more chaplains were brought out to assist in the growing work; among them came John Philip Gell, who interested himself largely in educational matters. When Tasmania was made a separate diocese in 1842, Francis Russell Nixon was appointed to the see. He was succeeded in 1864 by Charles Henry Bromby, who retired in 1882; Daniel Fox Sandford, the next appointee, was succeeded in 1889 by Henry Hutchinson Montgomery. His successor was John Edward Mercer, who resigned in 1914; Reginald Stephen, late dean of Melbourne, then became bishop, and on his translation to Newcastle in 1919 Dean Robert Snowdon Hay was consecrated, and is the present bishop (1925).

Victoria.—The first service in Victoria was held in 1834, in a barn on the Henty property at Portland; the barn was used for this purpose until it was replaced by a brick church in 1841. When the town of Melbourne was laid out in 1836, a small wooden church was erected on a site of five acres reserved for the use of the Church of England. Some zealous laymen ministered to the congregation until the arrival in 1838 of John Couch Grylls (q.v.); during the same year Bishop Broughton paid his first visit to the settlement. In 1839 the foundation-stone of St. James's church—which later became the pro-cathedral—was laid by Governor Latrobe. In September 1843 Bishop Broughton paid a second visit to the settlement, and laid the first stone of Christ-church, Geelong, on a site of two acres given by the government. In January 1846 the colonial government promised a sum of £11,000 towards the cost of St. James's,

providing an equal amount was subscribed by the public; Bishop Broughton added £500 to the building fund. In the same year work was begun on the church of St. Peter at Eastern Hill. In 1847 Melbourne became a separate diocese, with Charles Perry as first bishop; he was consecrated on 29 June, and held the diocese until his retirement in 1875. On 1 May of that year the diocese was divided, the western portion being constituted the diocese of Ballarat. James Moorhouse (q.v.) succeeded Perry at Melbourne; during his episcopate the foundation-stone of St. Paul's cathedral in Melbourne was laid on 13 April 1880, but the building (which was designed by the English architect Butterfield) was not completed and opened until 22 January 1891, in the time of his successor. When Moorhouse was translated to Manchester in 1886, Field Flowers Goe became bishop; he resigned in 1901, and during the interregnum the diocese was again subdivided, the dioceses of Bendigo, Wangaratta, and Gippsland being created in 1902. Henry Lowther Clarke was installed as next bishop on 3 March 1903. In 1905 Melbourne was raised to the dignity of an archbishopric. Archbishop Clarke resigned in 1920, and was succeeded by Harrington Clare Lees in February 1921.

The first bishop of Ballarat was Samuel Thornton; he was succeeded by Arthur Vincent Green, who was translated from Grafton and Armidale in 1900. When Dr. Green retired in 1917, M. H. Maxwell-Gumbleton of Bristol became bishop. The first bishop of Bendigo was Henry Archdall Langley, who was succeeded by his brother John Douse Langley in 1907. The present bishop, Donald Baker, took office in 1921. In 1902 Thomas Henry Armstrong was consecrated bishop of Wangaratta. Gippsland's first bishop was Arthur Wellesley Pain, who was succeeded by George Harvard Cranswick, the present bishop, in 1917.

South Australia.—The first chaplain, Charles Bernard Howard (q.v.), came out with Captain Hindmarsh in H.M.S. *Buffalo*. He conducted his early services in a tent, but soon began to erect the more permanent Trinity church; owing to financial troubles its construction was delayed, and he died in 1843 before he could complete it. His assistant James Farrell, who had arrived in 1840, carried on the work from 1843 to 1846, when Archdeacon Woodcock and James Pollett came to his assistance; G. Newenham and W. H. Coombes joined them later, and Coombes was stationed at Gawler. On 25 June 1847, by the munificent aid of Angela Burdett-Coutts, the see of Adelaide was established, and the first bishop, Augustus Short (q.v.), reached Adelaide on 28 December, and was installed in January 1848. He was soon faced by unforeseen difficulties, decisions of the local supreme court (which were confirmed by the privy council) depriving him of the cathedral-site which had been reserved by governors Gawler and Robe, and annulling the royal letters patent which had purported to confer on him a certain territorial and ecclesiastical jurisdiction within his diocese. Thus made head of a purely voluntary society with no privileges, Dr. Short threw himself ardently into the work of establishing his branch of the Church of England in a dignified and unassailable position; he traversed the diocese repeatedly—especially after 1856, when Western Australia was severed from it—and in his term of 34 years built up an organization with a synod, dean and chapter, endowments, church offices, a diocesan library, a theological college (St. Barnabas), two church grammar schools (St. Peter's college and the Pulteney school), and a partly built cathedral. When Short became bishop, the diocese had five ministers; when he resigned, it had 50, besides 212 lay readers.

In November 1881 symptoms of heart disease compelled his resignation. His successor was George Wyndham Kennion, whose term is notable for the establishment of a home mission society of the type founded by Bishop Barker in Sydney, and of a mission steamer which ministered to both the spiritual and the material needs of settlers along the Murray River. In 1894, having added more than 40 churches to the diocesan organization, Dr. Kennion was translated to the English see of Bath and Wells, and was succeeded by John Reginald Harmer, a well-known scholar and the literary executor of Bishop Lightfoot. During his episcopate the country parishes and missions were increased and systematized, and the cathedral was completed (the nave in 1901, the towers in 1902). In 1905 Dr. Harmer was translated to the English diocese of Rochester, and in 1906 Arthur Nutter Thomas became bishop. During his term the theological college has been enlarged and improved, a college (St. Mark's) has been established in affiliation with the university of Adelaide, the Pulteney school has been rebuilt on a better site, a Church secondary school for girls has been founded, the home mission fund has been extended in scope, and the stipends of mission clergy have been increased. In 1915 the northern archdeaconry was constituted the independent diocese of Willochra, Gilbert White being transferred from Carpentaria to become its first bishop. The diocese of Adelaide has now (1925) 106 ministers, 290 lay readers, and 178 churches: that of Willochra has 19 ministers, 68 lay readers and 44 churches.

Western Australia.—In 1848 Bishop Short of Adelaide, accompanied by Matthew Blagden Hale, paid a visit to Western Australia, then a portion of his huge diocese. At King George's Sound on 20 October they consecrated a stone church (which had been built in the rectorate of John Wollaston), and passed through Busselton, Bunbury, Picton, and Fremantle to Perth. There were then six clergymen in the colony, four of them in receipt of government stipends of £100 per year; the Church population numbered about 3700. They consecrated a church built for Postlethwaite on the upper Swan River, and another at St. George, and visited the middle Swan district, which was in the charge of W. Mitchell. The Adelaide diocese was far too large, and in 1856 was diminished by the formation of the diocese of Perth, with Hale as bishop. He remained in charge until 1875, when he was translated to Brisbane; he was succeeded by Henry Hutton Parry, coadjutor-bishop of Barbados, who was installed on 20 May 1877. Bishop Parry officiated till his death on 18 October 1894; his successor was Charles Owen Leaver Riley. Perth was raised to the dignity of an archbishopric in 1914.

In 1904 Frederick Goldsmith was appointed to the diocese of Bunbury, which had been created in the preceding year; Cecil Wilson became its bishop in 1917. In 1914 the diocese of Kalgoorlie came into being, with Cyril Henry Golding-Bird as bishop; he was translated to the Mauritius in 1919, and succeeded by William Edward Elsey. The independent diocese of North-west Australia was formed in 1910, with Gerard Trower as bishop.

Queensland.—On 18 September 1828 Governor Darling appointed John Vincent chaplain to the penal establishment at Moreton Bay, but he quarrelled with the commandant soon afterwards, and was recalled. The district seems to have been without Anglican ministrations until the end of the thirties, when John Macgregor, the first licensed clergyman, was appointed. In 1847 his charge became part of the new diocese of Newcastle. In 1848 Macgregor was succeeded by Benjamin Glennie, who was later assisted in his pioneering work by Robert Creyke and John Mosely. On 6 June 1859 Edward Wyndham Tufnell arrived to take charge of the newly-created diocese of Brisbane. He resigned in 1875, and was succeeded by Matthew Blagden Hale, who held the see until his resignation in 1885; William Thomas Thornhill Webber then became bishop. Dr. Webber died in 1904, and St. Clair George Donaldson (see DONALDSON, SIR S. A.) was consecrated bishop on 21 December of that year. In 1905 the Brisbane diocese was raised to the dignity of an archbishopric. Dr. Donaldson was translated to Salisbury in 1921, and Gerald Sharp of British New Guinea became bishop.

In the diocese of North Queensland, founded in 1878, the following bishops have officiated: George Henry Stanton (1878), Christopher George Barlow (1891), George Horsfall Frodsham (1902), and John Oliver Feetham. The first bishop of the Rockhampton diocese, which was formed in 1892, was Nathaniel Dawes (coadjutor at Brisbane, 1889); he was succeeded by George Dowglass Halford in 1909. In 1921 Philip Charles Thurlow Crick became bishop. The diocese of British New Guinea was created in 1898, with Montagu John Stone-Wigg as bishop; he was succeeded by Gerald Sharp, who became archbishop of Brisbane in 1921, and Henry Newton was appointed to British New Guinea in 1922. The diocese of Carpentaria, formed in 1900, has had three bishops—Gilbert White (1900-15), Henry Newton (translated to New Guinea in 1922) and Stephen H. Davies, who has held office since 1922.

The census of 1921 showed that out of a total population (for the Commonwealth) of 5,435,734 about 44 per cent (2,372,830) recorded themselves as belonging to the Church of England; this is a considerable proportionate increase on the figures of 1911, when only 38½ per cent of the population so recorded themselves.

The Legal Nexus.—All colonial branches of the Church of England are part of the mother-Church in so far that there is full inter-communion and constant interchange of clergy and laity—and occasionally of bishops. But some colonial Churches enjoy a considerable degree of autonomy, which has usually been provided for in their original constitution. The Church in Australia, however, is legally a collection of voluntary societies (dioceses formed either by legislative enactment or by consensual compact) each of which has been organized from the first on the basis of integral connection with the mother-Church, and which hold on trust a great deal of property which was given them because they are integral parts of that Church. In so far as they are voluntary societies the dioceses are quite at liberty to alter their rules and methods of procedure in any way the majority in each diocese may choose. As property-holders they have no such liberty; should a majority in any diocese decide to depart from conformity with the Church in England the seceders would risk the loss of all the existing property of the diocese, which could legally be claimed by the minority, however small, that preferred to abide in the mother-Church.

Since 1905 the question of reconstituting the Church in Australia on a purely autonomous basis has been discussed in synod after synod. This desire for autonomy is prompted by dissatisfaction with (*a*) the Prayer-book as it stands and (*b*) the judicial committee of the privy council as a final court of appeal, and by a widespread feeling that both in its name and constitution the Church should make a more direct appeal to Australian national sentiment. The general synod of the Church in Australia has on more than one occasion declared itself in favour of autonomy—in 1921 the voting was 20 bishops, 55 clergy and 48 laymen for autonomy, 19 clergy and 13 laymen against it—but the general synod is, as has been previously explained, powerless except when its decisions have been confirmed by the separate dioceses, and the desired powers can be obtained only by a very complicated process. A bill giving the Anglican dioceses power to alter their standards and formularies of faith and order, and to create for themselves a new 'tribunal of reference,' must be submitted to each State legislature and to the British parliament (since Australian Church property is held in England). If the seven bills are passed without serious amendment, there will be an end of any legal difficulties such as now hamper the reconstitution of the Church of England in Australia as a fully self-governing branch of the Anglican communion.

See Archbishop Clarke's *Constitutional Church Government in the Dominions* (1924), and the biographies of Richard Johnson, Samuel Marsden, and the various bishops elsewhere in this work.

J.V.C.-B.

Cicadas, insects of the family Cicadidae, belonging to the sub-order Homoptera of the order Hemiptera, are the most ancient as well as the most noticeable family of the Homoptera. About 150 species have been described as occurring in Australia, and they form a striking part of our fauna. During the summer they advertise their presence by a shrill, ear-splitting screech, which is sometimes kept up far into the night. Many species are large and handsome insects, and some do considerable damage to forest trees by sucking the sap. They are commonly but erroneously called 'locusts,' and some of the larger species have received apt vernacular names.

In the Sydney district two handsome cicadas are common, the Green Monday (*Cyclochila australasiae*) and the Double Drummer (*Thopha saccata*); the former is usually a vivid green, but there is a yellow variety called Yellow Monday. The drummer is black and red, and is remarkable for the large size of the tympani in the males—whence its name. Other well-known species are the Red-eye (*Psaltoda moerens*) and the Floury Miller (*Macrotristria angularis*), both names well describing the insect's appearance. Plate xix, fig. 7, shows a beautiful cicada from Queensland, *Psaltoda aurora,* allied to the red-eye.

Many species of the smaller cicadas are common, and some beautifully coloured. The most abundant genera are *Melampsalta* and *Pauropsalta,* which only differ from one another in

their venation. Amongst the more peculiar genera are *Cystosoma*, a genus containing the extraordinary bright-green bladder-cicadas, and *Tettigarcta*, an archaic genus confined to Victoria and Tasmania, which contains two hairy species lacking a sound-producing apparatus. In the latter genus the fore-wing shows very strongly a division into a tougher basal and a thinner distal portion (corium and membrane), thus indicating the essential unity of the Homoptera with the Heteroptera.

The life-histories of our Cicadidae have not been investigated, but it is certain that their life-cycle is shorter than that of the American 17-year cicada. Some of the smaller species (e.g. *Melampsalta torrida*) injure young apple-trees by frequent egg-slits, the branch breaking at the injured part. See HEMIPTERA. R.J.T.

Cinnabar. See MINERALOGY.

Cinnamomum, a genus of the family Lauraceae, consisting of trees or shrubs, extending over tropical and subtropical Asia to Japan. Three species are indigenous to Australia. *C. tamala* (Cassia Cinnamon), a large tree with a smooth bark, ranges from Queensland to India, where both leaves and bark are used medicinally —the leaves in the manufacture of a dye for printing calico, the bark as an ingredient in a special military soap. *C. Oliveri* (sometimes called Sassafras) is a tall tree of 60-80 feet, confined to the coastal brushes of New South Wales and Queensland. The bark has a strong aromatic odour and a pleasant astringent taste, and is frequently used by bushmen to improve the flavour of their tea. Its active principles are a volatile oil, with an odour like the North American sassafras, and a peculiar tannin. *C. virens* (Native Camphor Laurel) is a tree up to 90 feet, having a thin, non-aromatic bark and a soft, easily-worked timber.

Citrus, a genus of the family Rutaceae, one species of which is indigenous to eastern Australia. *C. australis* (Native Lime), is a tree of 30 feet, with oval or rhomboid leaves 1-2 inches long—the leaf-stalk not winged—and thorny branches. The fruits are nearly globular (1-1½ inches in diameter) with 3 or 4 slightly compressed seeds; their juice makes an agreeable beverage. The tree has a hard, close-grained, bright yellow timber, of the same texture as the wood of the common orange. For the imported citrus species grown in orchards see FRUIT-GROWING.

Clark, CHARLES (1838-1903), born in London on 19 April 1838 and trained for the ministry at the Nottingham Baptist College, after filling charges at Halifax, London, and Bristol was in 1868 made pastor of the Baptist church in Albert-street, Melbourne. Finding himself extremely popular as a lecturer (a lecture of his on Charles Dickens raised £600 for the Caxton memorial fund), he resigned his pastoral charge in December 1874 and entered on a career as lecturer and public entertainer. In this capacity he toured the Australian colonies, New Zealand, and the United States, and finally settled in England, though he on several occasions revisited Australia. He died in England in 1903.

Clarke, ANDREW (1793-1847), born at St. Kitts in the West Indies in 1793, entered the army at an early age (ensign, 1806; lieutenant, 1808; captain, 1813; major, 1825; brevet lieutenant-colonel, 1838; lieutenant-colonel, 1839) and became an officer in the 46th regiment, with which he came to Australia in 1814. He was almost immediately sent with a detachment to Hobart, where Macquarie made him inspector of public works, but afterwards rebuked him for trafficking in live-stock. He left Hobart for England in April 1816, and in 1818 rejoined his regiment for Madras. From 1839 to 1844 he was governor of St. Lucia in the West Indies, and in 1846 succeeded John Hutt as governor of Western Australia; but the period of service in the tropics (which must have commenced before his St. Lucia appointment) had undermined his health, and during his whole term in Western Australia he was a confirmed invalid. He died at Perth on 11 February 1847. (K.H., 1837.)—A younger brother, James Langton Clarke, was at one time a county court judge in Victoria; and to him Marcus Clarke (q.v.), the son of another brother, William Hislop Clarke, was sent out in 1863 by Andrew's son. J.S.B.

Clarke, SIR ANDREW (1824-1902), son of Colonel Andrew Clarke mentioned above, and cousin of Marcus Clarke the writer, was born at Southsea in Hampshire on 27 July 1824, educated at the military academy at Woolwich, and joined the royal engineers in 1844 (lieutenant, 1846; captain, 1854; major, 1863; lieutenant-colonel, 1867; colonel, 1872; major-general, 1884; lieutenant-general, 1886). In 1846 he was despatched to Tasmania to supervise road-making, and in 1848 transferred to New Zealand for similar work, but was employed also in negotiations with the Bay of Islands tribes, and dissuaded the promoters of a proposed Church of England settlement from establishing it in that district—it was subsequently located at Port Lyttelton. In August 1849 he returned to Tasmania to become private secretary to Sir W. Denison, with whom he had made a firm friendship; the next year he was nominated to the legislative council, and given charge of government measures. In 1853 he was transferred to Victoria as surveyor-general and chief commissioner of crown lands, with a seat in the council, and used his position to carry a useful bill enabling small centres of population to constitute a municipality in their district. When the new constitution came into force in 1855, Clarke's post ceased to exist, but he was at once made surveyor-general in Haines's first ministry and (having been elected by South Melbourne) retained his ministerial position until the defeat of his colleagues in March 1857; he was then, by a curious arrangement, made permanent head of his department without having to resign his seat in the legislature. In 1858 he even carried a vote of censure on the second Haines ministry, but refused to form a ministry himself.

From 1859 to 1863 he reverted to military duties in England; in the latter year he was sent to the Gold Coast, where he acted as chief justice in addition to his military work; in 1864 he was for a time agent-general for Victoria; and in August of that year he took up the directorship of admiralty engineering works, and for the next nine years was responsible for enlarging or constructing the great dockyards at Chatham, Portsmouth, Queenstown, Keyham, Malta, and Bermuda on which British fleets were to be based for many years to come. In 1873 (probably because it was an important naval station) he was made governor of Singapore, and during his term of office there put down local piracy and established more harmonious relations with the chiefs of the

Malay Peninsula. In 1875 he was transferred to India, where until 1881 he controlled the public works department and incidentally established the Indian defence committee. Returning to England in July 1881, he was for a year commandant of the military engineering school at Chatham, and then became inspector-general of fortifications, in which capacity he much encouraged inventors, advocating the use of the Brennan torpedo, the dirigible balloon, and the submarine long before either the admiralty or the war office could be persuaded to countenance them.

In all these years he had not forgotten Australia. In March 1886 he again acted as agent-general for Victoria, and impressed on the Imperial government the necessity of consulting Australia before making definite arrangements about the New Hebrides. In the same year he made an unsuccessful attempt to enter British politics, and consoled himself with directorships of many companies, including the British North Borneo Company. From 1891 onwards he devoted much attention to Australian affairs; he was agent-general for Victoria in 1891-4 and 1897-1902 (and for a short time agent-general for Tasmania also), was made an Australian representative on the Pacific cable board, and in 1900 assisted the Australian delegates in their discussions with the colonial office over the Commonwealth constitution bill. Busy and untiring to the last, he died in London on 29 March 1902. (C.B., 1869; K.C.M.G., 1873; C.I.E., 1877; G.C.M.G., 1885.)

Clarke, George (1823-1913), born at Parramatta in New South Wales on 29 June 1823, was the son of George Clarke, who came out from England as a missionary and in 1824 took his family to the Bay of Islands in New Zealand. There the younger George was once dandled on the knee of the terrible Hongi Ika ('Smell Fish'), the great Ngapuhi chief whose followers—armed with muskets which Hongi had earned in part by his help in compiling a Maori dictionary at Cambridge—in 1821 swept through the North Island like a destroying fire. After a few years at school in Hobart, George Clarke returned to New Zealand, where he was selected in 1841 as interpreter for the first criminal sittings of the supreme court of New Zealand. His work was specially important for the relations of the two races because at this sittings Maketu, a Maori, was tried for the murder of a white woman and her children. Maketu was condemned and hanged, but his fellow-Maoris were satisfied of the justice of the sentence. Clarke, whose mastery of the Maori tongue led him to speak scornfully of the knowledge possessed by the ordinary pakeha Maori, next acted as interpreter for Commissioner Spain, who had to deal with the land-purchase claims of the New Zealand Company and other traffickers in land. Clarke's advocacy of the rights of the Maoris made him very unpopular with some of the claimants. In 1844 he helped to arrange the purchase from the Maoris of 400,000 acres for the Scots colony of Otago, and he afterwards pointed with pride to the fact that no dispute ever arose over this deal. In 1846 Clarke left New Zealand to study for the Congregational ministry, and in 1851 became the minister of the Collins-street (afterwards Davey-street) Congregational church in Hobart, of which he retained charge for 52 years. He died at Hobart on 10 March 1913.

His learning, eloquence, saintly life, and zeal for education and religion, combined with a broad outlook and a genuine humanity, gave him an influence in the community such as perhaps no other man of his time possessed. With J. B. Walker (q.v.) and a few others he worked for the introduction of higher education, brought the university of Tasmania into existence against what seemed almost hopeless odds, and was its chancellor from 1898 to 1907. T.D.

Clarke, Sir George. See Sydenham, Lord.

Clarke, Marcus Andrew Hislop (1846-1881), born at Kensington on 24 April 1846 and educated at Chomley school, Highgate, on his father's sudden death was sent in 1863 by his cousin Andrew to Melbourne, where his uncle James Langton Clarke, a county court judge, secured him a clerkship in the Bank of Australasia. A few months' experience convinced him of his unfitness for office life, and in January 1865 he went off to gain 'colonial experience' on John Holt's station near Glenorchy on the Wimmera River; here he made acquaintance with bush types, acquired a modicum of bushcraft, and began to send sketches to the *Australian Magazine* under the *nom de plume* of Mark Scrivener. Tiring of bush life as of office life, he abandoned pastoral pursuits after a year's trial, and in February 1867 through the influence of Dr. Robert Lewin became a member of the literary staff of the *Argus* and *Australasian.* His serious work—reporting and leader-writing for the *Argus*—was on the whole a failure, but his contributions to the weekly paper, especially the series signed by 'The Peripatetic Philosopher,' soon brought him into notice. Always restless, however, in 1868 he (while continuing his work for the *Argus,* etc.) purchased the *Australian Magazine,* renamed it the *Colonial Monthly,* and in it published his first and weakest novel *Long Odds,* of which he wrote only the first five chapters. In May of that year he and some friends established the Yorick club. The *Colonial Monthly* was short-lived; he began to write verse and prose for the Melbourne *Punch,* but about the middle of 1869 brought out a rival comic paper *Humbug,* which lasted just three months. He then approached the publishers of the defunct *Humbug* with a proposal for a sensational convict novel, to be published in their *Australian Journal.* The offer was accepted, and he was sent to Tasmania to improve his health and pore over prison records. The result was *For the Term of His Natural Life,* which appeared serially in the *Australian Journal* between March 1870 and June 1872—surely the most dilatory serial ever published—was brought out in book-form, much condensed and improved, in 1874, and has since been republished in London, the United States, and many other countries. In June 1870 Redmond Barry made him clerk (afterwards secretary) to the trustees of the public library, and in 1873 he became sub-librarian; but such work was as alien to him as banking or reporting, and his time was really spent in literary composition of the most varied character, from psychology to pantomime. Spasmodic, improvident, worn out with constant living at high pressure, bitterly disappointed when on the librarian's death in 1880 he was not chosen to succeed to the post, and deeply wounded when in July 1881 the trustees requested his resignation on account of insolvency, Clarke died suddenly on 2 August in that year, technically of congestion of the liver.

The succession of events just narrated will convey an idea of Clarke's character. A brilliant writer and a fascinating comrade, he was so

essentially unstable that out of his crowded achievement only a single book has attained or deserves remembrance. Within 14 years he produced two novels, about 30 tales, a dozen comedies and burlesques, and many pamphlets, besides a considerable mass of journalistic work. Apart from *His Natural Life* (to use the abbreviated title by which the book is now known) and a few album verses, all these productions are practically valueless. The most notorious of them is a pamphlet, *The Future Australian Race*, published in 1877. He was entirely undisciplined. While writing for the *Argus*, he censured it violently in a rival newspaper; while secretary to the trustees of the library, he attacked a notable dignitary, Bishop Moorhouse, in the *Melbourne Review*. Yet his personality secured pardon for nearly all his vagaries. 'Sir Redmond Barry' wrote a high library official afterwards, 'and his fellow-trustees, and indeed most people who knew him, were very merciful to Marcus Clarke. Faults that would have gone far to ruin another man were overlooked in him.' Much admired, much beloved, but prodigal of his intellect as of his income, he left a name that Australians will be slow to forget. But he left also two legacies that have done Australia much harm—his preface to Gordon's *Poems*, which is a hopeless misreading of the bush, and his great but quite un-Australian novel, which depicts life in British prisons controlled by British officials, and has no more relation to ordinary colonial life than the diary of a governor of Dartmoor would have to the life of a Devonshire farmer.

Clarke, William Branwhite (1798-1878), born on 2 June 1798 at East Bergholt in Sussex, was educated at Dedham grammar school and Jesus College, Cambridge (B.A., 1821; M.A., 1824). At the university he attended the lectures of Professor Sedgwick and Dr. E. Clarke on geology, and acquired both an enthusiasm for and a considerable knowledge of the science; he also wrote verse of an undistinguished kind, being defeated by Macaulay in the competition for the Newdigate prize. In 1821 he took holy orders (priest, 1824), but did not settle down to parochial work, spending a great part of the next 18 years in travel through England and on the European continent and in scientific—mainly geological—investigation. In 1833 he was given the living of Longfleet in Dorset, and in 1837 became chaplain to the bishop of Salisbury. In 1839 he was advised to take a long sea voyage to restore his health; his decision to visit New South Wales was partly due to a wish to examine rock-structure in Australia. Arriving in Sydney, he was almost immediately appointed to the parish of Castle Hill and Dural, combining with it the nominal headmastership of The King's School at Parramatta—he had charge of the upper school, the lower school and boarding-house being left to J. Troughton, the former headmaster's brother-in-law. This arrangement, however, proved unsatisfactory, and at the end of 1840 Clarke resigned the headmastership, and was shortly afterwards transferred to parochial work at Campbelltown. In 1846 he became incumbent of St. Thomas's Church, North Sydney (then called Willoughby), and remained there till 1870.

His clerical work, however, while faithfully performed, was by no means his principal gift to Australia. As in Europe, so in Australia, his chief interest was science, especially geology. It is with the discovery of gold that his name is mainly associated in the popular mind; he is not actually the first discoverer—McBrien in 1823 had found some in the Fish River valley, and Strzelecki in 1839 found traces in the Vale of Clwydd—but his explorations were more persistent, and decisive of the fact that the precious metal existed in widespread deposits. Ignorant of previous discoveries, Clarke in 1841 obtained gold from the head of the Cox valley, in 1842 found it on the Wollondilly, in 1844 north of the Liverpool Range, and in 1845 in several places in the Bathurst district. But, as the convict population of New South Wales was still large and must not be abnormally excited, Governor Gipps prevented the discoverer from proclaiming his news. When the existence of gold was made public, Clarke of course set to work with renewed interest: he suggested that a field probably existed in Victoria, somewhere between 143° and 145° E. long. on or near 37° S. lat.—Hiscock on the hint found gold at Buninyong, and so led up to the great find at Ballarat; he also suggested possible fields in New Zealand, and so stimulated prospectors to work there. In 1851, having been commissioned by the government to make a survey of southern New South Wales 'with a special view to the indications of gold,' he spent nine exhausting months on the Monaro, round Kosciusko, and on the upper Murray, without much result as far as gold was concerned. For his work then and previously he was awarded at different times £6000 by colonial governments. Nor was gold the only object of his research. In 1877 he received the Murchison medal of the London Geological Society for his work on the New South Wales coal-fields; and as early as 1849 he discovered the existence of deposits of tin.

The date of his appointment to the secretaryship of the Australian Museum is still in doubt. George Bennett, his predecessor, resigned the post on 1 February 1841, and Clarke's formal appointment as 'secretary and curator with salary' dates from 6 July of that year; but the Museum minute-book contains an entry showing him as secretary on 2 January 1839. He retired from this office in 1845. He was a member of the council of the Australian Philosophical Society when it was resuscitated in 1850; its vice-president when in 1856 it became the Philosophical Society of New South Wales; and one of its two permanent vice-presidents when in 1866 it was again transformed to the Royal Society of New South Wales. (The governor for the time being was always president, so that Clarke's position was the highest attainable.) He was to the last an exceedingly active member, and the titles of his papers range from 'Deep Sea Soundings' to 'The Effect of Forest Vegetation on Climate.' He was at all times a busy writer, though his only books are the *Researches in the Southern Goldfields of New South Wales* that narrated his journey of 1851, and the *Remarks on the Sedimentary Formations of New South Wales*, the fourth edition of which he completed a fortnight before his death. In 1876 he was made a fellow of the Royal Society, for his work on gold discoveries, at a time when that honour was very rarely conferred for work in Australia. After 1870, when he retired from clerical work, he devoted himself entirely to science, and died on 17 June 1878, the acknowledged leader of scientific thought in Australia. After his death the government bought his collection of fossils for £7000.

Clematis, a large genus of the family Ranunculaceae, consisting of climbing plants,

widely dispersed over temperate regions. Five species are endemic in Australia. The plants climb by means of leaf-stalks, which coil over the branches of trees; the cream-coloured unisexual flowers are borne in large trusses, the sexes on distinct plants; the petals are obsolete, being represented by coloured calyx-lobes; the fruits are terminated by the persistent base of the style, which is plumed and curved like an ostrich-feather. *C. aristata* and *C. glycinoides* are coastal species, the former ranging from Western Australia to Queensland, the latter not extending westward beyond Victoria. *C. microphylla* is found on the coast and inland in all the States. The coastal species are somewhat indiscriminately known by various names that properly belong to English species of clematis —'traveller's joy,' 'virgin's bower,' and 'old man's beard.'

Clerodendron, a genus of the family Verbenaceae, consisting of trees, shrubs (rarely herbs), and woody climbers. It is mainly tropical in habitat, largely Asiatic, with a few African and American species. Several species indigenous to Australia are ornamental shrubs with large white (or cream-coloured) fragrant flowers. The calyx is enlarged and persistent; corolla-tube slender, 5-lobed; stamens protruding, occasionally thread-like; fruit more or less succulent, separating into 4 nuts; leaves opposite or in whorls. *C. inerme,* a species found in north-eastern Australia, also occurs in India, where they extract an exquisite perfume from the flowers. The succulent leaves are bitter,

Sturt's Desert Pea (*Clianthus Dampieri*).

and yield a quantity of mucilaginous juice with a slightly saline but intensely bitter taste, sometimes used as a febrifuge. *C. tomentosum* is frequently found near tidal waters. It has a soft, porous wood of a bright yellow colour.

Clianthus, a genus of the family Leguminosae, containing two species, one endemic in Australia, the other limited to New Zealand. *C. Dampieri* (Sturt's Desert Pea), found in the interior of Australia, is a prostrate herb covered with a dense vestiture of long greyish silky hairs. The magnificent scarlet blooms, with a glossy purplish disk on the upper petal (standard), are arranged in a drooping cluster of several flowers at the top of the stem. This plant, being hard to raise, is not commonly seen in gardens; the excessively hard coating of the seed has to be softened by a thorough soaking before germination can take place. The New Zealand *C. puniceus* is an ornamental shrub, bearing red or white flowers.

Clifton, MARSHALL WALKER (1787-1861), born 1 November 1787, was the son of F. Clifton, prebendary of Lincoln, and a scion of the Cliftons of Clifton in Nottingham. For some years secretary to the royal navy victualling board, he afterwards became chief commissioner of the company that promoted the settlement at Australind (q.v.). He settled there in 1841, devoted his efforts to the prosperity of the settlement, and died there in 1861. J.S.B.

Climate. See METEOROLOGY AND CLIMATE.

Close, EDWARD CHARLES (1790-1866), born at Rangamati near Calcutta on 12 March 1790 and educated at Ipswich in Suffolk with a view to taking holy orders, in 1808 abandoned the Church for the army (ensign, 1808; lieutenant, 1809), serving in the Peninsula and taking part in the battles of Talavera, Busaco, Albuera, Vitoria, the Nivelle, Orthes, and Toulouse. In 1817 he came with his regiment (the 48th) to New South Wales, and in 1821 was acting engineer at Newcastle, but at the end of that year seems to have resigned his commission and settled down as a landowner at Green Hills, now the town of Morpeth; to the 2000 acres he held there he soon added another 3800, thus becoming one of the biggest landholders in the Newcastle district. The Green Hills property, lying along the ridge at the head of the Hunter navigation, was the obvious site for a township; but Darling's attempts to recover the grant without giving Close an equal area elsewhere delayed resumption until the impatient settlers had planted themselves on the low land of West Maitland, and Close's later subdivision of his Green Hills land did not attract them back. Made a magistrate in 1822, he was in 1827 involved in the trouble over the shooting of aborigines on Dr. Bowman's land (for which see LOWE, NATHANIEL) and removed by Darling from the magistracy; he was not, however, long in disfavour, being appointed on 1 February 1829 an original member of the newly constituted legislative council. From this position he retired in 1839, and lived quietly on his estates until his death on 7 May 1866.

Club-mosses. See LYCOPODIALES.

Coachwhip-birds (*Psophodes*), a genus of terrestrial, scrub-haunting birds peculiar to Australia. Coachwhip-birds are among the anomalous perching birds (Passeriformes) of the continent,

and their relationship to other forms is quite uncertain. By Gould they were placed with the lyre-birds (Menuridae) and more recent authors have regarded them as Timaliidae.

The common Coachwhip-bird (*P. olivaceus*) occurs in suitable country all along the east coast from northern Queensland to eastern Victoria. Concealed among the dense vegetation, it is far more often heard than seen. Its calls consist of a series of loud musical notes ending

Coachwhip-bird.

in a crack like that of a whip. Usually the crack is immediately followed by two notes sounding like 'twit-twit,' regarding whose source there has been much discussion. It is now certain that they are usually uttered by the other bird of the pair; one bird, however, may sometimes be responsible for the whole performance. By gradually approaching the spot whence the calls are uttered, and then remaining quiet for some time, it is generally possible to see one or more of the birds. They are about the size of thrushes, in colouring a very dark bronzy-green, with black heads and white patches on the cheek and in the centre of the breast; the head bears a bushy black crest. They feed on the ground, scratching up leaves and turning over small stones with their powerful feet, and at intervals repeating their call. Sometimes they elevate their crests and spread their long broad tails, or chase one another through the vegetation and round or over fallen logs. The nest, an open cup-shaped structure of twigs, fibres, and rootlets, is built in a bush surrounded by thick scrub. The eggs, two or three in number, are pale blue with black spots and lighter scrawls.

The only other species of the genus is the Black-throated Coachwhip-bird (*P. nigrogularis*) of south-western Australia. This species differs remarkably from its eastern relative in habits and song; it frequents tea-tree thickets among the coastal sandhills, and utters a peculiar, harsh, grating song. It does not appear to have been met with for many years past, and is probably extinct.

W.B.A.

Coachwood, the vernacular name of *Ceratopetalum apetalum*, a tall (50-100 feet) and highly ornamental tree with a smooth bark and harsh toothed leaves 3-6 inches long, growing in mountain gullies. The calyx, at first small, enlarges and reddens when the fruiting season arrives; as the petals are obsolete, this coloured calyx—as with the Christmas Bush (q.v.)—is

Coachwood.

popularly supposed to be the flower. The timber is valuable, but not obtainable in quantity, as the tree usually chooses an almost inaccessible habitat; it is largely used in coach-building, especially for the frames, where it is considered equal to English ash. Owing to the presence of coumarin in the sap, the bark when wounded gives off an odour like that of the Tonkin bean. See CERATOPETALUM.

Coal. The principal and the first-discovered coal-fields in Australia are those of New South Wales; they are for convenience' sake classified as northern, southern, and western, but form a single continuous basin comprising three series of payable seams. The upper (Newcastle) series, which outcrops at Newcastle in the north, Bulli in the south, and Lithgow in the west, for many years provided the main supply of coal. The middle (Tomago) series is worked chiefly in the Maitland area. The lowest (Greta) series, unknown 40 years ago, has of late years become the most important in Australia.

The first discovery of coal in Australia was made by chance and not thought worth following up. In June 1796 fishermen brought pieces of coal to Sydney from 'a bay near Port Stephens,' where they said there was a good deal more lying on the surface. Again in May 1797 a party of seamen from the wrecked *Sydney Cove*, during their overland journey from the Ninety-mile Beach in Victoria to the settlement on Port Jackson, found lumps of coal on the beach at Coalcliff (now Clifton) a few miles north of Bulli, and their discovery was confirmed later in the year by George Bass. But the locality was difficult of access, and the seam was neglected in favour of the northern field, which was discovered in September of the same year by Lieutenant Shortland at the mouth of the Hunter River. Owing to the lack of small craft to fetch the coal to Sydney, and also to the fear of a mutiny of convicts at sea, the governor took no steps to work this field; but private merchants were permitted to collect small cargoes, some of which were shipped to India towards the end of 1799—this being the first export of coal from the colony. A cargo was also collected from the shores of Lake Macquarie, in August 1800. Governor King, on his arrival, set the only expert miner in the colony (a convict with a life sentence) to search for the mineral in the neighbourhood of Sydney; being unsuccessful in this, and having been ordered by the colonial

office to send coal to the Cape of Good Hope, he despatched an expedition under Colonel Paterson to the Hunter River in June 1801, and, receiving a favourable report, established there a small penal settlement to procure coal and timber. He also issued on 3 July 1801 an order declaring the coal and timber of the Hunter River district to be the exclusive property of the crown and ordaining that persons engaged in the coal trade must be licensed. Coal was now obtained for colonial use, several cargoes were sent to India, and in November 1801 a first shipment was made to the Cape. Owing to administrative difficulties King in 1802 closed the establishment, but it was reopened in March 1804 under the name of Newcastle. The government monopoly then declared was maintained until 1831, when the mines were taken over by the Australian Agricultural Company (q.v.).

When Commissioner Bigge visited Newcastle in 1820 only 27 convicts were employed in raising coal, and a little later the whole revenue derived from the industry was £500 a year: Bigge therefore recommended that the mines should be leased for a term of years, an annual rent and a proportion of the coal won being reserved for the crown. The colonial office willingly opened negotiations with the Australian Agricultural Company, which sent a manager and some plant to New South Wales; but Governor Darling was against the change and refused to transfer the mines without direct orders from home, and the company's local advisory committee disliked the proposal, so the manager had to go back to England. However on 6 August 1828 Darling was definitely ordered to transfer to the company two blocks (one of 1500 acres, one of 500) in the Hunter River district, and to cease operations in the government mine as soon as the company was ready to take over control; but if the company did not in any one year raise a certain specified quantity of coal the colonial government could resume the mines. A quit rent was to be paid, and coal enough for the government's own requirements would be delivered at the pit-head at prime cost. For 31 years no governor, without the previous sanction of the colonial office, was to grant or convey any local mines or land containing coal without a specific exception of the coal, or to assign convict labour for coal-mining. In 1831 the company took over the mines, and to avoid competition not only bought up land at Newcastle but protested against an application made in 1838, and supported by the governor, to work coal at Western Port, and a second application in 1839 by Captain Westmacott to open up the Bulli field. The crown law officers, however, refused to admit that the company had a monopoly, and there was no official interference with the southern enterprise, which nevertheless proved abortive. There was no active competition in the industry until in 1845 James Brown opened a pit at Four-mile Creek near East Maitland on 60 acres of land originally granted to Colonel Dumaresq. Proceedings were initiated against Brown, but while the case was on appeal information was received in Sydney that the company had agreed to terminate the alleged monopoly. In 1850 the governor cancelled the reservation of coal made in all grants theretofore issued, and the Australian Agricultural Company had to face increasing competition. Of late years the centre of the northern coal-field has shifted from the Newcastle to the Maitland district, the great wealth of which was first recognized when in 1886 Edgeworth David (q.v.) located an outcropping coal seam in a creek near Abermain, and traced it to Cessnock. Early in 1889 a syndicate acquired 250 acres in this new field, and in 1891 the East-Greta Coal-mining Company was formed. The Greta coal-measures are worked under an area extending from Cessnock north to Muswellbrook; their coal is very hard and of excellent quality for gas-making and household purposes, but makes too much black smoke for use by warships. Its seams are of exceptional thickness, some ranging as high as 32 feet, and in the Stanford-Merthyr colliery first-class coal is worked 22 feet in thickness without a band. The Greta series also appears at the southern end of the coal area, on the Clyde River, but its coal there is of inferior quality.

The southern (Bulli) field, though first discovered, was not opened up until 1857 owing to the difficulty of reaching it, Illawarra being accessible from Sydney only by sea or down the steep sides of the coastal range. In 1857, however, the Mount Keira pit was worked, the output for May of that year being 142¾ tons. In 1858 the Bellambi colliery was opened, the coal being taken in carts to the beach and there put aboard small colliers lying off the unsheltered coast. Developmental work at Bulli followed, and in 1862 the South Bulli pit was opened. Transport facilities were gradually improved, jetties being run out either wherever a curving beach provided shelter from southerly gales or—as at Clifton, north of Bulli—straight from the pit-mouth in the side of a cliff. In 1901 harbour improvements at Port Kembla, south of Wollongong, made transport from the southern collieries much safer and easier. The two worst disasters in the history of Australian mining occurred in southern pits—at Bulli on 23 March 1887, when 81 persons were killed, and at Mount Kembla on 31 July 1902, when 95 were killed. Bulli coal is a good steam-coal, frequently used by Australian warships, being more nearly smokeless than any other coal in Australia that is produced on a commercial scale.

In the western coal-field, between the Blue Mountain spur and the main dividing range, mining began during the late sixties, the Hartley measures being opened up by Saywell and Grand at Bowenfels, by Woolley and Anderson and by Thomas Brown in the Lithgow valley, and by Andrew Brown at Cooerwull. In 1869 the output was 1360 tons, of late years it has averaged 1¼ million tons. It is essentially a steam coal, but inferior to the southern coal. In 1916 the New South Wales government opened a State coal-mine at Lithgow.

In 1847 W. B. Clarke asserted that workable seams of coal would be found to occur under Sydney, and later geologists pointed out that the northern, southern, and western measures were part of one vast, continuous geologic basin. Boring carried out towards the end of last century proved the existence of coal under the city, and in 1903 the Sydney Harbour Collieries Company was formed to work the seam from a shaft at Balmain. After many vicissitudes the mine, which has a depth of 2784 feet, was temporarily abandoned in 1917.

A few scattered fields of minor value also occur in outlying parts of New South Wales. In 1915 sub-bituminous black-coal measures were found to underlie an area of about 23,000 acres in the Riverina district. These deposits have associated with them a large overburden of kaolin of high quality, the profits from which it is hoped will go towards meeting the cost of

mining. A company has been formed to work this deposit, and a shaft has been sunk at Coorabin; but no serious attempt has been made to utilize the lignite deposits which occur in various localities, or the Triassic coal-measures of the Clarence and Richmond River districts, which are intersected by bands and contain a large percentage of ash. The yield in the three main fields of New South Wales for 1922 (the latest year for which detailed statistics are available) was: northern, 7,156,921 tons, southern, 1,878,594 tons, western, 1,147,618 tons, making the total for New South Wales 10,183,133 tons, the Australian output for the same year being 12,208,617 tons. The New South Wales total for 1924 was 11,618,216 tons.

Certain seams in each of the three areas produce good coking coal. The best comes from the Bulli seam; it is exceedingly strong and specially suitable for smelting purposes, by reason of its capacity for sustaining the weight of the ore burden in the blast furnace. It has a specific gravity of 1.88 to 1.9, whereas that of western district coke rarely exceeds 1.8, and northern coke may go as low as 1.72.

Queensland.—The coal resources of this State, which are still comparatively untapped, are of vast extent and wide distribution. The southern field (Ipswich-Darling Downs) was first worked, and is still the centre of the most extensive operations, chiefly because of the facilities for export. In 1843 John Williams opened a pit on the south bank of the Brisbane River to meet the requirements of the Hunter River Steam Navigation Company, which was then running steamers to the northern settlement; by 1851 Williams was prepared to deliver supplies to residents of Brisbane. At a later date collieries were opened north and south of the Bremer River to work the bituminous Ipswich seams, and others farther west on the Darling Downs, where cannel coal occurs. In the Wide Bay district seams have been worked since the seventies, the Burrum mines being the most productive. The Rockhampton district has extensive deposits of great variety and good quality. Near the Styx River the State is working excellent bituminous coal, the only deposit in the central district that is suitable for gas-making purposes; it is of a natural coking variety. In 1891 a party of gold prospectors found a 30-ft. seam free of bands on the Callide Creek, a tributary of the Dawson, but it was not until 1901 that large and valuable seams of anthracitic and semi-anthracitic coal were found to underlie the area between the Mackenzie and Dawson rivers. Two collieries near Baralaba on the Dawson River line are now being worked, one by the State and the other by the Mount Morgan Gold-mining Company; this coal contains up to 86 per cent of fixed carbon and only 4 or 5 per cent of ash. Extensive seams of hard, clean, bituminous, non-coking coal (with 60 per cent fixed carbon, 28 per cent volatile hydrocarbon, and 5 or 6 per cent ash) occur round Clermont; this coal was first found at Blair Athol in 1864 during the sinking of a well. Bores were put down by the Peak Downs Copper Mining Company, which required coal for copper-smelting, and worked the seam until 1879. In 1886 there were further developments, and the field was surveyed in 1889. It is only within the last decade, however, that the value of the deposits has been recognized. Edgeworth David has estimated the coal in the field to aggregate 258,000,000 tons; the maximum thickness of the seams so far ascertained is 93 feet.

In the north the Bowen coal strata were early recognized, and more importance was attached to them than subsequent discoveries warrant. Meanwhile the name 'Bowen River beds' had been extended to cover wide areas where the formation is geologically identical with these earlier-known strata. Since 1919 the State has worked a mine in the Bowen field. In the Cook district the beds cover more than a thousand square miles: the Little River field near Cooktown was examined in 1882, but the only deposits actively worked are at Mount Mulligan, from which coal is obtained for the State smelters at Chillagoe. The only true anthracite in Queensland occurs at Mount Bopple near Maryborough, where a small seam of anthracite and one of graphite are separated by a few inches of baked shale. At Waterpark Creek, between Rockhampton and Mackay, there are large and neglected deposits of brown coal.

The Queensland fields, therefore, are for the most part still undeveloped. The yield in the chief mining centres in 1922 was:—

Ipswich	579,484 tons
Darling Downs	93,524 „
Wide Bay	79,305 „
Central (Rockhampton) ..	68,075 „
Clermont	104,141 „
Bowen	11,506 „
Mount Mulligan	22,484 „

In 1922 the total output was 958,519 tons. But the actual reserve of coal, according to the government geologist, is 412 million tons, and the probable reserve 2201 million tons.

Victoria.—In this State coal was first discovered in 1825, near Cape Paterson, but no attempt was made to work it until the Port Phillip settlement was officially established in 1838. In June of that year Governor Gipps forwarded to the colonial office an application from some Tasmanians for leave to open coalmines on Western Port in order to supply the increasing demand for coal across the strait. Little came of the application. Between 1838 and 1873 unsuccessful attempts were made to work the coal, and the colonial government spent considerable sums in assisting boring operations in different localities on the recommendation of private individuals. In 1873 an expert from New South Wales was invited to report on the field in the neighbourhood of Cape Paterson. In his report, which was very unfavourable, the expert pointed out that these seams were of later formation than the coal-measures of New South Wales; he saw no reason to hope that seams of any thickness or persistence would be found in the district. Interest thereupon flagged. But as a result of discoveries made from 1878 onward in the Hazelwood Range, at Mirboo and in other localities in southern Gippsland, the government agreed to assist boring operations there, and after 1889 (up to which date the total production in the colony was only 25,000 tons), the industry was somewhat stimulated, the Coal Creek Company at Korumburra being registered in that year, the Jumbunna Company in the following year and the Outtrim, Howitt, and British Consolidated in 1894. In 1908 an extensive field was discovered in the Powlett River district, the seam being of good, clean, hard coal averaging six feet in thickness. The government decided to work the field itself, and in 1909 the establishment of a state coal-

mine was legalized. Operations were begun towards the end of the year, and a township, Wonthaggi, was laid out on modern lines. The production of black coal in Victoria in 1922 was 559,284 tons, of which 511,174 tons were produced by the state mine.

In addition to its deposits of black coal, all of which occur in the southern Gippsland district, Victoria possesses extensive fields of brown coal and lignite. Little effort was made to utilize these until 1917, when an advisory committee recommended the establishment of an open-cut mine at Morwell for the development of a scheme of electric power generation. For details of subsequent work on this field see MORWELL. In 1922 90,402 tons of brown coal were produced.

Western Australia.—In March 1839 the government of the Swan River colony offered 2560 acres in fee simple to any person who discovered any considerable bed of coal; the offer was repeated several times, but, although sporadic efforts were made to work coal near the Murray River, in the Irwin district, on the Phillips River (near Albany), and at Fly Brook (the south-eastern tributary of the Donnelly River), no field of commercial value was found until 1889, when a carboniferous formation noted in the Collie district by a local farmer was proved to be true coal. A company was formed, but was obliged to abandon work for lack of capital. After a favourable report by an expert from New South Wales the government undertook a series of borings which proved the existence of a field about 50 square miles in extent with seams of a total thickness of about 137 feet; the Collie railway was then built, and operations begun on a commercial scale. Collie coal is non-coking, semi-bituminous, and singularly deficient in volatile materials: it occurs in two distinct types, one characterized by low moisture and sulphur and oxygen contents and high ash and carbon content, the other exactly opposite in character (high moisture, low ash, etc.). Coal has been found at several other places in the south-west, and a 12-foot seam has been discovered in the valley of the Fitzroy River in the far north: but no commercial use has been made of any of these finds. The output of the Collie mines in 1922 was 438,443 tons.

Tasmania.—In 1803 coal was found at the head of the Coal River, near Lake Tiberias, but was not worked. John Busby (q.v.), who visited Tasmania on his way to Sydney in 1824, reported favourably on both this seam and one discovered on Schouten Island, and in 1826 equally good reports were made on deposits at South Cape Bay and on the western shores of D'Entrecasteaux Channel; but the high cost of mining and transport prevented further development of these seams, although the Coal River deposits were worked intermittently. There was also a mine, worked by convicts for the use of the penal settlement at Port Arthur, on Tasman Peninsula. Strzelecki in 1842 reported on seven Tasmanian seams, but only the upper Coal River seams (Jerusalem and Jericho) were praised; in 1850 coal was discovered on the Mersey River, but the industry remained at a standstill until in 1855 excellent seams were opened up in the Fingal district on the eastern coast. In 1922 the Tasmanian coal-yield was 69,238 tons, over 90 per cent of it coming from the Fingal mines of the Mount Nicholas field. The island also possesses beds of lignite and brown coal, but these have not been exploited.

South Australia.—In this State there is no active coal-mining. Bituminous seams have been found near Robe in the south-east, Kuntha Hill on the Barcoo, and Lake Phillipson in the far west, north of Tarcoola; a sub-bituminous deposit is known at Leigh Creek, east of Lake Torrens; brown coal has also been found, and lignites are widely distributed.

The total amount of Australian coal (exclusive of bunker coal) exported to other countries in 1922-3 was 1,114,115, practically all from New South Wales. The principal ports of destination were New Zealand (394,701 tons); Philippine Islands (139,194 tons); United States (123,504 tons); Chile (107,351 tons); India (104,013 tons); Netherlands East Indies (73,170 tons); Hawaiian Islands (54,706 tons); Straits Settlements (43,967 tons). In 1922 there were 27,057 persons employed in coal-mining in Australia; the average death-rate from accident during the quinquennium 1918-22 was 1.57 per 1000 miners.

An excellent discussion of the coal resources of Australia will be found in the *Report to the World Power Conference* of 1924 made by the Australian Institution of Engineers.

Coccidae, insects of the sub-order Homoptera and order Hemiptera, often called scale-insects, gall-lice, or mealy-bugs. They are very abundant in Australia, more than 300 species having been described, most of which are so remarkable that they deserve special notice—interested readers should consult the works of Maskell, Schrader, Fuller, and Froggatt. Most Australian plant-galls are caused by coccids of the sub-family Apiomorphinae, usually known as 'brachyscelid' galls from the original but pre-occupied name of the genus. Many of these galls are of huge size and bizarre form, e.g. the huge bifurcate gall formed by *Apiomorpha duplex* on branches of trees. In the Monophlebinae are included many large species of 'mealy-bug;' *Monoph'ebus crawfordi* measures up to an inch in length. In the genus *Callipappus* the females are large 'mealy-bugs,' while the males are beautiful insects known as bird-of-paradise flies, their delicate tail-threads resembling spun glass; the best-known Australian species is *C. australis* (plate xix, fig. 11). Australia has also numerous species of the true scale-insects—small insects, the mature males with two wings and the females wingless, which, owing to their habit of constructing scale-like matter beneath which they live, are readily transported on nursery plants or cuttings. The San Jose Scale (*Aspidiotus perniciosus*) has done more damage and caused more alarm to fruit-growers than any other insect. A few years after its introduction into the United States, it caused the death of various fruit-trees—especially apples and stone-fruit—over thousands of acres. Restrictive legislation was passed, expeditions to obtain parasitic checks were sent out, and useful natural enemies to it were found in its native home, China. In Australia it is kept well under control by its natural enemies, ladybirds of the genera *Rhizobius* and *Scymnus*.

Only one Australian scale-insect has proved

troublesome; but this species, the Cottony-cushion or Fluted-scale (*Icerya purchasi*), is exceptionally dangerous, as in 1906 it was reported to have threatened the extinction of the orange-growing industry in California. Only after the failure of mechanical remedies was the introduction of an Australian ladybird (*Novius cardinalis*) found effectual. This ladybird has also been effectively introduced into the orchards of South Africa, Italy, and elsewhere, as the enemy of *Icerya*. In Australia this scale is not a serious pest to fruit-trees, but attacks other trees, especially acacias.

Several indigenous species of *Kriococcus* are widely distributed in Australia, and are often dense on eucalypts and other native plants. *E. eucalypti* was accidentally introduced into New Zealand, where it damaged eucalyptus plantations till the introduction of one of its natural enemies (*Rhizobius ventralis*) kept it in check. The same ladybird has been useful in America. The Saltbush-scale (*Pulvinaria maskelli*) in some years greatly reduced the sheep-carrying power of land by the serious damage it did to saltbush in large areas of New South Wales, South, and Western Australia. *Frenchia casuarinae* causes galls on she-oaks, and often kills the branches; it is abundant in New South Wales, Victoria, and Tasmania; but the male has yet to be found.

Many cosmopolitan species have been introduced into Australia, causing annual losses of thousands of pounds. Among them are various species of *Dactylopius* (mealy-bug); one is a serious pest on the sugar-cane, another attacks pine-apples, a third is found at the roots of potatoes and other plants, and few plant-houses are free from the attacks of *D. adonidum*. The ladybird *Cryptolaemus montrouzieri* may often be seen feeding on mealy-bugs, and has been introduced into Hawaii in order to get rid of them; a good deal of success has been obtained. The Mussel-scale of the apple (*Mytilaspis pomorum*) injures trees and disfigures fruit in Tasmania and the cooler parts of Australia. Fumigation is almost useless as a remedy, since the eggs are laid beneath a covering scale; nevertheless fumigation on a vast scale is practised on Tasmanian apples before being permitted to enter mainland ports. The Mussel-scale of citrus fruits (*M. citricola*) affects the coastal regions of eastern Australia, and a few other species of the genus are frequently seen in plant-houses. The Red-scale of the orange (*Aspidiotus aurantii*) is a serious and widespread pest that is combated by fumigation with hydrocyanic acid gas and by oil emulsion sprays, or, at worst, by destroying affected trees. *A. rapax* (black), *A. rossi* (purple), and *A. ficus* are also very troublesome.

The Rose-scale (*Diaspis rosae*) sometimes encrusts the stems of the rose, blackberry, and raspberry, giving the appearance of white-wash. The Indian Wax-scales (*Ceroplastes ceriferus* and *C. rubens*) are very common in New South Wales and Queensland, where they have extended their attacks to such native plants as *Bursaria spinosa* and the bracken fern. Another abundant pest is the black or brown *Lecanium oleae*, that amongst other plants especially attacks the lemon, olive, and oleander; an allied species, *L. hesperidum*, selects the orange. In Western Australia the large Vine-scale (*L. berberidis*) has been troublesome, but is now largely kept down by chalcid parasites. See HEMIPTERA.

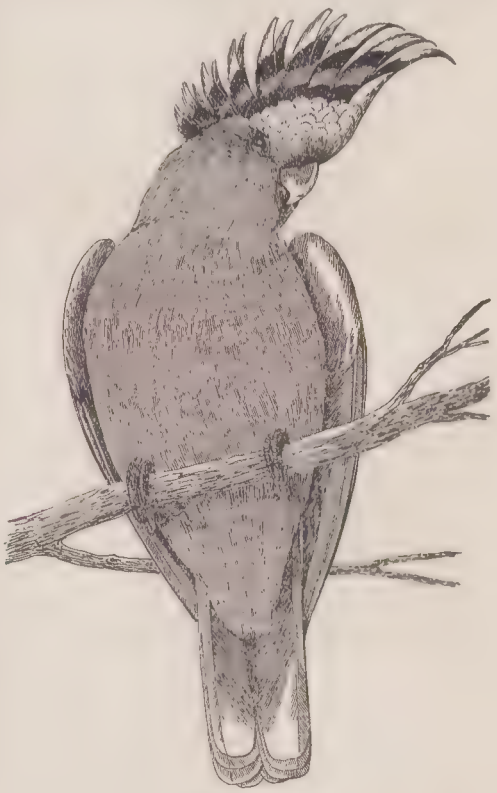
R.J.T.

Cockatiel. See PARROTS.

Cockatoo Bush. See MYOPORUM.

Cockatoos, large arboreal birds, with strong hooked beaks, feet with two toes turned each way, erectile crests and comparatively short tails, belonging to the family Cacatuidae and the order Psittaciformes (parrots).

Cockatoos are confined to the Australian region, extending from Tasmania through Australia, New Guinea, and the Moluccas to the Philippines, Celebes, and Lombok. In Australia and Tasmania 11 species occur, by far the best-known being the Sulphur-crested White Cockatoo (*Cacatua galerita*) found in New Guinea, northern and eastern Australia, and Tasmania. The most beautiful is the 'Major Mitchell' or Pink Cockatoo (*C. leadbeateri*) which is found inland. The Galah or Rose-breasted Cockatoo (*C. roseicapilla*) is another inland form plentiful almost throughout Australia, and the Bare-eyed Cockatoo (*C. sanguinea*) is abundant in the northern and



Pink Cockatoo.

central regions of the continent. The Corella or Long-billed Cockatoo (*C. tenuirostris*) was at one time common both in south-eastern and south-western Australia, but has now become very scarce, and seems to be approaching extinction.

The species mentioned are all very noisy birds; they associate in large flocks, and feed chiefly on roots, bulbs, and seeds—which they obtain on the ground, digging up the roots with their beaks. They are intelligent and wary; when a flock is feeding, sentinels are generally posted in neighbouring trees to give warning of the approach of danger. They nest in holes in trees (occasionally in cliffs), and

lay white eggs. In captivity they live to a great age, instances of birds living to 80 or even 100 years being not infrequent; and individuals possess an imitative faculty that enables them to learn and speak long sentences.

Black cockatoos—which constitute a separate section of the family—are more arboreal than their white relatives; they have very stout bills, by the aid of which they split open the woody capsules of eucalypts and the hard wooden fruits of proteaceous trees. They also tear off bark, and feed on the large wood-boring insect-larvae thus revealed. The largest of the black cockatoos is the Palm Cockatoo (*Probosciger aterrimus*) found in the Aru Islands, New Guinea, and northern Queensland; the most widespread is the Banksian or Red-tailed Cockatoo (*Calyptorhynchus banksi*), found throughout the continent, especially far inland; the most familiar —to most Australians—are the Funereal Cockatoo (*C. funereus*) of the south-east and Tasmania, and the White-tailed Cockatoo (*C. baudini*) of the south-west. Black cockatoos are shy birds and, owing to the difficulty of feeding them, are hardly ever seen in cages.

Funereal Cockatoo.

The smallest cockatoo is the Gang-gang (*Callocephalon fimbriatum*) of south-eastern Australia and Tasmania, where it lives in pairs in thick forest country. It is a grey bird, with a curious loose crest; the plumage of the female is entirely grey, but the male has head and crest scarlet.

W.B.A.

Cockburn, Sir John Alexander, was born on 23 August 1850 at Corsbie in Berwickshire, educated at Highgate and King's College, London (M.D., 1874; fellow), and in 1875 migrated to South Australia, settling at Jamestown as a medical practitioner. In April 1884 he was returned for Burra to the legislative assembly, and was minister for education in the Downer ministry (1885-7), founding during his period of administration the school of mines and industries. In April 1887 he was returned for Mount Barker, and held this seat until his retirement from politics in 1898. In June 1889 he became premier, and passed important acts dealing with succession duties and a progressive tax on unimproved-land-values. Defeated in August 1890, in June 1893 he joined the Kingston ministry as minister for education and agriculture, and from 1898 to 1901 was agent-general for South Australia in London. Keenly interested in federation, he represented his colony at the conferences of 1890, 1891, and 1897-8, devoting special attention to the advocacy of woman suffrage and 'one man one vote.' Since 1898 he has been a permanent resident of London. He severed his official connection with South Australia in 1901, but has maintained touch with Australia partly by acting as South Australian or Commonwealth representative at various international congresses and by presiding over the Australian chamber of commerce in London, partly by his many writings for the British press on Australian subjects. In 1901 he published a small volume of essays on Australian federation. (K.C.M.G., 1900.)

Gang-gang.

Cockle. Sir James (1819-1895), born on 14 January 1819 and educated at Charterhouse and Trinity College, Cambridge (B.A., 1842; M.A., 1845), studied for the law, was called to the bar in 1846, and made himself so good a reputation that at the instance of Chief Justice Erle he was appointed first chief justice of Queensland. This position he held from 1863 to 1879, when he returned to England, and

died on 29 January 1895. His legal attainments were of a high order, and only two of his judgments were ever reversed on appeal; he also left his mark as senior commissioner on the consolidation of Queensland statute law. His favourite science was mathematics; he was the author of upwards of 80 papers, most of them dealing with pure mathematics, and made important contributions to the theory of equations, especially differential equations. He was elected a fellow of the Royal Society in 1865, while in Queensland, and after his return to England he became a most active member of the London Mathematical Society, serving on its council from 1881 to 1890 and being president in 1886-8. During his residence in Queensland he was president of the Queensland Philosophical Society, which afterwards became the Royal Society of Queensland. (Kt. Bach., 1869.)

Cockspur. See CUDRANIA.

Cod. The family of Gadidae, so important in the fisheries of the northern hemisphere, is represented in Australia by a few species restricted to the colder waters of the south. The Red Cod (*Physiculus barbatus*), the best-known, occurs in considerable quantities on the Tasmanian and Victorian coasts, and ranges northwards to New South Wales waters during the colder months. It is an important food-fish in the southern markets. The so-called Ling or Beardie (*Lotella callarias*) is an allied species occurring on the south and south-eastern coast-line; it does not command much favour as a food-fish. Several species of other genera taken in deep water by trawlers are rather more closely allied to the true cod (*Gadus*) of the northern hemisphere, and may prove of commercial value, if they can be secured in sufficient quantity. The so-called 'rock cod' and 'Murray cod' are described under those names.

A.R.McC.

Ling or Beardie.

Cockroaches, insects of the family Blattidae, belonging to the order Orthoptera, were much more numerous in past ages, forming the dominant group in the insect faunas of the upper Carboniferous and Permian eras. They are still comparatively abundant in Australia, where about 47 genera and 270 species have been described. Sixty per cent of these species have the tegmina and wings functionless in both sexes, while a further 10 per cent have them functionless in the females only. This condition is of very great interest, and is correlated (as Dr. Eland Shaw has pointed out) with the gradual adoption of the habit of living in communities under rotten wood or in burrows in the soil. The wingless condition has evolved furthest in the *Polyzosteria* group of genera, the well-known 'black-beetles' of the bush, abundant everywhere; the best-known genera are *Polyzosteria*, *Cutilia*, *Platyzosteria*, and *Cosmozosteria*. *Polyzosteria mitchelli* (plate xix, fig. 1) is an exceptionally beautiful cockroach. Our largest native cockroaches are *Geoscapheus giganteus* and *Macropanesthia rhinocerus*, which attain a length of 2½ inches.

Among the winged forms, some handsome species hide under the bark of trees. *Methana marginalis* is a large, dark-brown cockroach with the tegmina strongly bordered with white on the costal area. Other common species belong to the genera *Panesthia*, *Escala*, *Ischnoptera*, and *Ellipsidion*. Species common in houses are the small *Blattella germanica* and the large *Periplaneta americana*, both introduced; the latter has almost completely replaced the original species, *P. australasiae*, in Australia. See ORTHOPTERA.

R.J.T.

Coelenterata, radially symmetrical, diploblastic (two-layered) animals. The most important members of this group are:—

Class Hydrozoa. Polyps and medusae with ectodermal gonads and no vertical partitions in the enteron; e.g. hydroid zoophytes (q.v.) and bluebottles (q.v.).

Class Scyphozoa. Medusae with endodermal gonads, and with a gullet and vertical partitions in the enteron of the polyp stage (when the latter exists); e.g. large jelly-fishes (q.v.), such as *Aurelia*.

Class Actinozoa. Polyps without a medusoid generation, and with endodermal gonads, a gullet, and vertical partitions in the enteron; e.g. sea-anemones (q.v.) and corals (q.v.).

E.A.B.

Coffee. In the warm north-eastern corner of New South Wales coffee succeeds well, but except on a very small scale has never been grown for market. In many coastal districts of Queensland it thrives to perfection, and about 1890 was planted to some extent; but in consequence of low prices and labour difficulties many plantations were abandoned. The maximum production was reached in 1901-2, when an area of 547 acres was recorded. In 1908 there were 285 acres under trees in bearing, which produced 116,293 lb. of (parchment) coffee. The chief producing districts were Cairns, Maroochy, Mackay, and Maryborough. After 1908 the cultivation gradually declined to 21 acres in 1922-23 (almost entirely in the Cairns dis-

trict) the quantity raised being 9368 lb. The quality of the coffee produced is good, and the trees grow well and yield prolific crops.

W.S.C.

Cole, GEORGE WARD (1793-1879), born on 15 November 1793 and entered as a volunteer in the navy in 1807, served through the rest of the French wars on the West Indies and North Sea stations, and was wounded at New Orleans in December 1814 while in command of a gunboat. In 1815 he was made a lieutenant, retired on half-pay in 1817, and in 1837 was gazetted commander. Between 1817 and 1839 he was engaged in the merchant service, and in 1840 settled in Victoria and helped to found the Port Phillip Steam Navigation Company. He also built the first private wharf on the Yarra, and the first screw steamship to be launched (on 20 February 1851) south of the equator. He took some interest in local politics, combining with Fawkner in 1848 to nullify the Port Phillip elections to the Sydney legislative council, and himself representing Gippsland in the Victorian council from 1853 to 1855. In 1859 he was elected by the central province to the new council, and held the seat till his death; from 1863 to 1868 he represented the first McCulloch ministry in the council, though holding no office. He died on 26 April 1879.

Coleoptera. See BEETLES.

Coles, SIR JENKIN (1842-1911), born in Sydney on 19 January 1842, taken by his parents to England in 1849, and educated at Christ's Hospital in London, returned to Sydney in 1858 and after a time settled in South Australia. For some years he served in the mounted police, then became an auctioneer, and in July 1875 was elected to the legislative assembly for the district of Light. From 1878 to 1881 he was out of parliament, but in 1881 was re-elected for Light, and retained the seat until 1902, when his constituency was merged in Wooroora, and he became member for that district. In the Colton ministry of 1884-5 he and Thomas Playford held alternately the commissionerships of crown lands and public works, and in Playford's ministry of 1887-9 Coles was commissioner of crown lands. From 1890 to 1911 he was speaker of the legislative assembly, but retired in November and died on 6 December 1911. (K.C.M.G., 1894.)

Collembola. See SPRING-TAILS.

Collins, DAVID (1756-1810), born at Exeter on 3 March 1756 and educated at the local grammar school, joined the marines—the Plymouth division of which his father then commanded—in 1770 (2nd lieutenant, 1771; 1st lieutenant, 1775; captain-lieutenant and captain, 1779; brevet lieutenant-colonel in army, 1798; brevet colonel in army, 1808), fought at Bunker's Hill, was made adjutant of the Chatham division at the end of 1776, and in 1782 served aboard H.M.S. *Courageux* at Lord Howe's relief of Gibraltar. Next year, at the peace, he was placed on half-pay, but in 1786 volunteered for service with the detachment of marines destined to accompany Phillip's expedition to New South Wales, and on 24 October was appointed deputy-judge-advocate on Phillip's staff. This appointment made him practically the head of the settlement's judicial system; he was president of the civil court with two nominees of the governor to assist him, and president of the criminal court with six naval or military officers to assist him. He had no special knowledge of law, but great industry and a considerable fund of commonsense fitted him for the work, and the precedents he established both in form and matter were respected (with a very few exceptions) until the establishment of a real supreme court in Macquarie's time. On 1 January 1787 he was appointed judge-advocate of the marines also. He held his first criminal court in Sydney on 11 February 1788 (three cases of assault and larceny among the convicts) and his first civil court on 1 July. In June Phillip made him also secretary to the governor, so that he was by far the most powerful man in the settlement next to Phillip himself; and from first to last his conduct was above suspicion, and Hunter in 1795 told the British authorities that he knew no individual in the colony 'whose absence would be so heavily felt by the public service . . . . if he were now impatient to quit the colony, I cou'd not, without exposing it to the most manifest injury, give my consent to his doing so.' In 1792 he had asked for leave of absence and had obtained it from England, but was detained for four years longer in New South Wales, 'because of the consequence which each successive commanding officer considered him of to these settlements.' The long delay injured him personally; after the departure of the marines for England in 1791 he lost his pay as judge-advocate of the detachment, his half-pay ceased because he was holding a civil appointment, and on his return to England (which he reached on 26 July 1797) he was informed that, owing to his long absence and detachment from marine duties, he could only return to active service as junior captain in the corps. Refusing this indignity, he was partially compensated by the grant of a brevet-colonelcy in the army. He now devoted himself to the preparation of a book describing the first 10 years of the colony's existence, about which more is said in another paragraph; this was published in 1798. Tired of a restful existence, on 10 September 1800 he suggested to Sullivan (under-secretary for war and the colonies) that he should be appointed to the department as a special officer in charge of New South Wales affairs; this suggestion passed unnoticed, probably because of the confusion then existing in British politics, and on 15 November 1801 he made a second attempt, with the aid of the Duke of Portland, to obtain either employment or compensation for his previous losses. It was possibly due to Portland's aid that, when towards the end of 1802 the colonial office decided to make a settlement on Port Phillip, Collins was chosen to lead the expedition, and on 14 January 1803 was commissioned 'Lieutenant Governor of a Settlement or Settlements to be formed on the Southern Coast of New South Wales to the northward of Basses Streights.' The story of his abortive attempt to settle on Port Phillip will be found under VICTORIA, and that of his successful settlement on Storm Bay in southern Tasmania under TASMANIA; here it may be said that he left England in H.M.S. *Calcutta* on 25 April 1803, reached Port Phillip on 9 October, abandoned it on 30 January 1804 (transporting his party in the *Ocean*), landed at Risdon Cove on 16 February, and almost immediately moved across the river to Sullivan's Cove, on which Hobart now stands. From this centre for six years he ruled with good judgment, but under an ever-increasing burden of difficulties, the southern half of the island. He was merely a deputy for the governor of New South Wales;

consequently his despatches to England were never acknowledged or commented on, he had practically no judicial mechanism (both criminal and civil suits being supposed to be tried in Sydney), his supply of convicts—the only source of labour—came from Sydney only and was scanty (Sydney had none too many for its own use), and his supply of provisions had the same origin and the same fatal defect. He obtained one great access of settlers from Norfolk Island (q.v.), but this only increased his need of labour and provisions without providing any fresh resources worth mentioning. His staff of assistants was young, inexperienced, and too often careless about public affairs and loose in private conduct. Towards the end of his life his troubles were still further complicated by the disturbances in New South Wales consequent on the deposition of Bligh—who on 31 March 1809 landed at Hobart and attempted to use it as a base of operations against Paterson and the irregular government at Sydney. Collins, who depended entirely on Sydney for supplies, refused to allow this, and Bligh angrily denounced him to the British government. Macquarie on his arrival, knowing only Bligh's side of the case, anticipated the lieutenant-governor's recall and his supersession by Foveaux, but maintained friendly relations with him; and on 24 March 1810 Collins died suddenly in his chair. Lieutenant Lord, his young successor, in an endeavour to give public expression to the widespread regret for this loss, ran up an account of over £500 for the funeral expenses; and Macquarie, while feeling bound to disallow the amount himself, strongly recommended the authorities in London to pay it. In 1813 the British government granted the widow a pension of £120 a year.

Apart from Collins's work as a public servant, his chief claim to remembrance is his authorship of the *Account of the English Colony in New South Wales*, which he published in 1798. This work is invaluable as a faithful chronicle of the early years of the settlement, its chief fault —a lack of imagination in the writer—being at the same time its principal virtue. He took his writing seriously, wasted little time over descriptions of scenery or gossip about his fellow-officials and their bickerings, and kept always in view his purpose of narrating actual history exactly and with judgment. The picture he draws is in consequence not a lively or amusing one, as Tench (q.v.) in his account shows it might have been; but it is essentially trustworthy, and beyond doubt the most valuable printed record of the period. Throughout he writes as a witness, giving firsthand evidence. In his second volume, however, which was published in 1802, he is merely a transcriber with some special knowledge. The greater part of his matter is borrowed from Hunter, and long extracts are made from King's journals as regards New Zealand and from Bass's as regards the famous voyage of the *Norfolk*. In 1804 the two volumes were combined and somewhat abridged by his wife; it is this 2nd edition that has usually been reprinted, and many so-called 'histories' issued since then are merely transcripts from its pages. The illustrations, it may be mentioned, were engraved from water-colour drawings made by Edward Dayes (who was never in New South Wales) from sketches made in the colony, apparently by a convict artist, Thomas Watling (q.v.). W.J.

Colonial Office, The. The relations of the Australian colonies with the mother-country have been since their foundation carried on through the British colonial office under that or other names. A list of ministers controlling this office from the first settlement of Australia onwards is therefore given here for convenience of reference. The names by which they were best known are in italics: titles in parentheses were conferred on them after their term of office was at an end: (2), (3), (4) before a name indicate the 2nd, 3rd, 4th time of holding the office.

In 1782 colonial affairs were dealt with by a subordinate branch of the home department, styled the plantations branch; but on 5 March 1784 this business was transferred to a committee for trade and foreign plantations, still under the home department.

Secretaries of State for the Home Department:—

Thomas Townshend, Viscount *Sydney*	22 January 1784
William Wyndham *Grenville*, Baron Grenville	5 June 1789
Henry *Dundas* (Viscount Melville)	8 June 1791
William Henry Cavendish Bentinck, Duke of *Portland*	7 August 1794

In 1794 the home department handed over the management of the war with France, which it had previously exercised, to a new war department, and Dundas was made secretary for war. Owing to a misunderstanding the colonies (which Pitt intended to keep under Dundas) remained with the home department, but the committee for trade was no longer employed to supervise their affairs. The actual amalgamation of the war and colonial departments was not accomplished until 1801; even then the administration of convict affairs remained with the home office.

Secretaries of State for the War and Colonial Departments:—

	Robert *Hobart* (Earl of Buckinghamshire)	March 1801
	John Jeffreys Pratt, Marquess of *Camden*	May 1804
	Robert Stewart, Viscount *Castlereagh* (Marquess of Londonderry)	July 1805
	William *Windham*	February 1806
(2)	Viscount *Castlereagh*	March 1807
	Robert Banks Jenkinson, Baron Hawkesbury, Earl of *Liverpool*	December 1809
	Henry Bathurst, Earl *Bathurst*	June 1812
	Frederick John Robinson, Viscount *Goderich* (Earl Ripon)	30 May 1827
	William *Huskisson*	23 September 1827
	Sir George *Murray*	23 May 1828
(2)	Viscount *Goderich*	22 November 1830
	Edward George *Stanley* (Earl of Derby)	28 March 1833
	Thomas *Spring-Rice* (Lord Monteagle)	June 1834
	George Hamilton Gordon, Earl of *Aberdeen*	20 December 1834
	Charles Grant, Baron *Glenelg*	April 1835

Secretaries of State for the War and Colonial Departments (*continued*):—

	Constantine Henry Phipps, Marquess of *Normanby*	February 1839
	Lord John *Russell*	August 1839
(2)	Lord *Stanley* (Earl of Derby)	August 1841
	William Ewart *Gladstone*	20 December 1845
	Henry George Grey, Earl *Grey*	June 1846
	John Somerset *Pakington* (Baron Hampton)	February 1852
	Henry Pelham Fiennes Pelham Clinton, Duke of *Newcastle*	28 December 1852

In 1854, during the Crimean war, the two departments were separated, and the colonial office properly so called came into existence, in charge of a secretary of state.

Secretaries of State for the Colonies:—

	Sir George *Grey* (of Fallodon)	10 June 1854
	Sidney *Herbert* (Baron Herbert of Lea)	10 February 1855
(2)	Lord John *Russell**	15 May 1855
	Sir William *Molesworth*	21 July 1855
	Henry *Labouchere* (Baron Taunton)	17 November 1855
(3)	Lord *Stanley*	26 February 1858
	Sir Edward Bulwer *Lytton* (Baron Lytton)	31 May 1858
(2)	Duke of *Newcastle*	18 June 1859
	Edward *Cardwell* (Baron Cardwell)	4 April 1864
	Henry Howard Molyneux Herbert, Earl of *Carnarvon*	6 July 1866
	Richard Plantagenet Campbell Temple Nugent Bridges Chandos, Duke of *Buckingham* and Chandos	8 March 1867
	Granville George Leveson-Gower, Earl *Granville*	10 December 1868
	John Wodehouse, Earl of *Kimberley*	6 July 1870
(2)	Earl of *Carnarvon*	21 February 1874
	Sir Michael Edward *Hicks Beach* (Viscount St. Aldwyn)	4 February 1878
(2)	Earl of *Kimberley*	28 April 1880
(4)	Lord *Derby*	16 December 1882
	Sir Frederick Arthur *Stanley* (Earl Derby)	24 June 1885
(2)	Lord *Granville*	6 February 1886
	Edward *Stanhope*	3 August 1886
	Sir Henry Thurstan Holland, Lord *Knutsford*	14 January 1887
	George Frederick Samuel Robinson, Marquess of *Ripon*	17 August 1892
	Joseph *Chamberlain*	28 June 1895
	Alfred *Lyttelton*	9 October 1903
	Sir Victor Alexander Bruce, Earl of *Elgin* and Kincardine	11 December 1905
	Sir Robert Offley Ashburton Crewe-Milnes, Earl of *Crewe* (Marquess of Crewe)	16 April 1908
	Lewis *Harcourt* (Viscount Harcourt)	7 November 1910
	Andrew *Bonar Law*	27 May 1915
	Walter Hume *Long*	11 December 1916
	Alfred *Milner*, Viscount Milner	14 January 1919
	Winston Leonard Spencer *Churchill*	14 February 1921
	Victor Christian William Cavendish, Duke of *Devonshire*	25 October 1922
	James Henry *Thomas*	23 January 1924
	Leopold Charles Maurice Stennett *Amery*	November 1924

*Russell accepted office in February, but was not formally installed in the department till May.

In June 1925 the colonial office was reorganized, the affairs of the Dominions being segregated under a new 'Secretary of State for Dominions Affairs.' To this office L. C. M. S. Amery was for the time appointed; his Dominions staff, however, is housed in the colonial office, the control of which he still retains.

Communication with the colonies has been usually kept up through the permanent under-secretaries, and a list of these is appended. For parliamentary and assistant under-secretaries and other officials the current *Colonial Office List* should be consulted.

Permanent under-secretaries for the Colonies since 1825:—

Robert William Hay (1825), Sir James Stephen (1836), Herman Merivale (1847), Sir Frederick Rogers (1859), Sir Robert George Wyndham Herbert (1871), Sir Robert Henry Meade (1892), Sir Edward Wingfield (1897), Sir Montague Frederick Ommanney (1900), Sir Francis John Stephens Hopwood, afterwards Lord Southborough (1907), Sir John Anderson (1911), Sir George Vandeleur Fiddes (1916), Sir James Edward Masterton-Smith (1921).

Before the reorganization of the colonial office in 1825 official communication with the authorities in Australia was carried on by secretaries of several departments. Phillip and Hunter corresponded with Philip Stephens, secretary of the admiralty from 1763 to 1795, after whom Cook named Port Stephens in New South Wales; Evan Nepean, under-secretary of the admiralty (1782-94), under-secretary for war (1794-5), and secretary of the admiralty (1795-1804); John King, under-secretary of the admiralty in 1792-3, while Nepean was on sick leave, and his successor from 1794 onwards; Charles Long (afterwards Baron Farnborough), secretary to the treasury from 1791 to 1801; and Sir George Yonge, secretary for war from 1783 to 1794. In King's time John Sullivan, an under-secretary for war from 1801 to 1805, took up the correspondence, and a certain M. Lewis seems to have acted as secretary during another of Nepean's illnesses; many official letters were addressed to another member of Lord Hobart's staff, James Chapman. Edward Cooke, who had been an under-secretary for war since 1802, in May 1804 relieved Sullivan of the New South Wales correspondence. King and Bligh also transacted a good deal of business with William Marsden, secretary of the Admiralty from 1804 to 1807, and Bligh with William Wellesley-Pole (afterwards Lord Mornington), who in 1807-9 succeeded Marsden. Macquarie's correspondents were Charles Cecil Cope Jenkinson (afterwards Earl of Liverpool),

under-secretary for war from 1809 to 1810; John Wilson Croker, secretary of the admiralty from 1809 to 1830; Robert (afterwards the great Sir Robert) Peel, an under-secretary for war from 1810 to 1812; Henry Goulburn, who succeeded Peel and was under-secretary until 1821; Henry Edward Bunbury, who was also an under-secretary for war from 1809 to 1816; and John Barrow, second secretary of the admiralty from 1807 to 1845. In Brisbane's time Robert Wilmot (who in 1823 changed his name to Horton) succeeded Goulburn, and in 1825 handed over the affairs of the colonies to Robert William Hay, mentioned above.

Colonies, Creation or Separation of. The mainland of Australia was by Phillip's commission of 1786 divided into two parts at 135° E. long. It was at that time believed that Tasmania was a part of the mainland, but in 1798 Flinders and Bass sailed through Bass Strait and so established its insular character. The original territory of New South Wales, therefore (including New Zealand, which Cook had annexed and Phillip's commission covered), was thus:—

	Square miles
Australia, east of 135° E. long.	1,454,312
Tasmania	26,215
New Zealand	104,471
Total	1,584,998

AUSTRALIA AND NEW ZEALAND, 1786-1836.

On 14 June 1825 Tasmania was constituted a separate colony; this reduced the area of New South Wales to 1,558,783 square miles. In July 1825 the inland boundary of New South Wales was extended westward to the 129th meridian, thus increasing its area by 518,134 square miles to 2,076,917 square miles. Four years later Captain Fremantle annexed 'all that part of New Holland which is not included within the territory of New South Wales,' i.e. the region west of the 129th meridian, comprising 975,920 square miles; this became the colony of Western Australia.

On 15 August 1834, by the Act 4 and 5 William IV cap. 95, the province of South Australia was constituted, and on 28 December 1836 the new colony was officially proclaimed. It embraced 309,850 square miles, lying south of 26° S. lat. and between the 141st and 132nd meridians, which had been part of New South Wales. Thus the area of the mother-colony was reduced to 1,767,067 square miles.

The governors of New South Wales had never taken New Zealand seriously under their jurisdiction, except in so far as they exercised the right of forbidding Englishmen to go there. When it became necessary for some one to exercise a definite authority, the islands were in 1840 first proclaimed a dependency of New South Wales and then, by letters patent of 16 November of that year, constituted a separate colony. Proclamation of the separation was made on 3 May 1841. This separation reduced the political territory of New South Wales to 1,662,596 square miles. In 1846 an attempt was made by W. E. Gladstone, then colonial secretary, to establish a purely penal colony without free settlers (at least at the outset) to be called Northern Australia (see GLADSTONE COLONY). It was to consist of such of the

AUSTRALIA, 1859-1861.

territories of New South Wales as lay north of 26° S. lat. But Earl Grey, the next colonial secretary, almost immediately abolished the colony, and the territories comprised in it reverted to New South Wales.

On 1 July 1851 what had been known as the 'Port Phillip district' of New South Wales was constituted the colony of Victoria, 'bounded on the north and north-east by a straight line drawn from Cape Howe to the nearest source of the River Murray, and thence by the course of that river to the eastern boundary of the colony of South Australia.' The area of the new colony was 87,884 square miles, so that the territory of New South Wales and reduced to 1,574,712 square miles. In pursuance of this process of subdivision, letters patent dated 6 June 1859 granted an independent administration to 'so much of the colony of New South Wales as lies northwards of a line commencing on the sea coast at Point Danger, in latitude about 28° 8′ south, running westward along the Macpherson and Dividing ranges and the Dumaresq River to the Macintyre River, thence downward to the 29th parallel of south latitude and following that parallel westerly to the 141st meridian of east longitude, which is the eastern boundary of South Australia, together with all the adjacent islands, their members, and appurtenances in the Pacific Ocean.' The western boundary was not specifically defined, but by inference was the 141st meridian. The actual separation of Queensland dates from 10 December 1859; its area at this time was 554,300 square miles. New South Wales was thus divided into two parts—one of 310,372 square miles (the present State) and another of 710,040 square miles lying between the meridians of 129° and 141°. No more colonies have been created; but the isolated block just referred to as part of New South Wales has been divided up between South Australia, Queensland, and the Northern Territory. The strip of country south of 26° S. lat. and between the 132nd and

129th meridians, with an approximate area of 70,220 square miles, was on 10 October 1861 (by the authority of the Imperial act 24 and 25 Victoria cap. 44) added to South Australia. By letters patent dated 13 March 1861—which reached Australia and became effective in 1862—a northern strip, described as 'so much of the colony of New South Wales as lies to the northward of the 26th parallel of south latitude, and between the 141st and 138th meridians of east longitude, together with all and every adjacent islands, their members and appurtenances, in the Gulf of Carpentaria' was added to

AUSTRALIA, 1861-1906.

Queensland. The area of South Australia was therefore increased to 380,070 square miles, and that of Queensland to 670,500 square miles. On 6 July 1863 the remainder of the block (thenceforth known as the Northern Territory), containing 523,620 square miles, was by letters patent brought under the jurisdiction of South Australia.

In 1863 was initiated a movement for the separation of the Riverina district of New South Wales—which in those days meant, roughly speaking, the area west of 147° E. long.—from the parent colony. It was a squatters' movement, prompted by the passing of the Robertson land acts (see LAND LEGISLATION), and would have placed nearly half the colony in the possession of about 20,000 people. The proposal was discussed and rejected by the legislative assembly on 16 February 1864; undismayed, the promoters in 1865 forwarded petitions to the colonial office, but were again snubbed, the British authorities thinking it absurd to create a colony without access to the sea, in which the largest town had a population of 800 and only half a dozen more had over 100. Several other attempts have since then been made to split up the existing colonies or States, notably the agitation in Queensland during the nineties for the creation of a new 'North Queensland' centring on Townsville and a new 'Central Queensland' centring on Rockhampton, and the movement at present (1925) existing to create 'new States' in northern New South Wales and in the Riverina—which nowadays means the area bounded by the Murray on the south and elsewhere by a line running through Menindie, Hillston, Narrandera, and Albury. Proposals have also been made in the Commonwealth parliament for the abolition of all present State boundaries and the re-subdivision of Australia into about 20 provinces. But none of these proposals has yet approached success.

From 1863 onwards, therefore, the mainland of Australia was divided into five mutually independent colonies and a 'territory,' while the near-by island of Tasmania and the distant New Zealand were considered informally as part of the same great group of colonies. Between 1885 and 1899 the movement towards federation (q.v.) gathered strength, and eventually brought the mainland colonies and Tasmania into a federal union; New Zealand remained outside, and on 1 January 1901 six colonies and one territory became the 'Commonwealth of Australia,' the designation 'colonies' being at the same time changed to 'States.' The only change in political subdivisions since then was made on 7 December 1907, when the Commonwealth and the State of South Australia entered into an agreement by which the Northern Territory passed under direct Commonwealth jurisdiction. Approval was given by the South Australian legislature under the Northern Territory surrender act 1907 (assented to on 14 May 1908) and by the Federal parliament under the Northern Territory acceptance act 1910 (assented to on 16 November 1910). The Territory was transferred by proclamation to the Commonwealth on 1 January 1911. The total area of the Commonwealth is 2,974,581 square miles. The dates of creation and the areas of its several parts, as determined on the final adjustment of their boundaries, are shown in the following table:—

Colony.	Year of Formation into Separate Colony.	Present Area in Square Miles.
New South Wales ..	1786	310,372
Tasmania	1825	26,215
Western Australia ...	1829	975,920
South Australia	1836	380,070
Victoria	1851	87,884
Queensland	1859	670,500
Northern Territory ..	1863	523,620

Colton, SIR JOHN (1823-1902), born in Devonshire on 20 September 1823, migrated with his father to Adelaide in 1839, and for 20 years pursued a commercial career. In 1859 he entered municipal politics, and in 1862 was elected to the assembly from Noarlunga, but after a term of official life as commissioner of public works in the Strangways ministry (1868-70) left office and parliament in May 1870. Noarlunga again returned him in 1872, and in 1875 he joined James Boucaut (q.v.) as treasurer, leaving him when the ministry was reconstructed in March 1876 and defeating him on a vote of no confidence in June. Colton then formed a ministry of his own in which members of both parties came together, and carried through a big railway construction programme, but in October 1877 he came into collision with the legislative council, which went so far as to depose formally its official leader the chief secretary, Sir Henry Ayers, and elect William Morgan (q.v.) in his place. Displaced by Boucaut in October 1877, Colton again left parliament in 1878, but in 1880 was persuaded to stand once more for Noarlunga, was re-elected, and in 1884 formed a ministry that introduced to office C. C. Kingston and Jenkin Coles, and with the aid of W. B. Rounsevell and R. C. Baker (q.v.), carried an act embodying the principles of land and income taxation. Defeated by John Downer in June 1885, Colton finally left parliament in 1887, paid a long visit to England, and died at Adelaide on 6 February 1902. He was never

a strong partisan, and his frequent resignations were prompted mainly by a business man's dislike of parliamentary delays and squabbles; but he had a keen eye for nascent ability, reinforced his ministries with young men who afterwards became notable, and always retained the personal friendship of his political opponents. He interested himself greatly in Prince Alfred College, and his treasurership of that institution is commemorated by a Colton scholarship and a Colton wing in the buildings. (K.C.M.G., 1892.)

Combretaceae, a widely distributed family, consisting of trees, shrubs, or woody climbers, largely tropical. Of the four genera indigenous to Australia, three are also found in America, Africa, and Asia; the fourth is endemic in Australia. The flowers are in spikes or heads; calyx-tube narrow with 4 or 5 teeth-lobes; petals small or none; stamens inserted on the calyx; fruit usually a drupe with a leathery coat; cotyledons folded or convolute. The most important genus is *Terminalia* (q.v.).

Commerce. See TRADE AND COMMERCE.

Commonwealth Bank, THE. On 22 December 1911 an act to provide for a Commonwealth Bank came into force. The establishment of such a bank had for some years been advocated by the Labour party, and the sixth 'plank' of its fighting platform in 1908 demanded a 'Commonwealth Bank of Issue, Deposit, Exchange and Reserve, with non-political management.' The party's considered scheme proposed that the bank's nominal capital must be held by the Commonwealth and such States as chose to join in, the Commonwealth holding at least 6000 shares and no single State more than 1000. Besides ordinary banking business the bank was to issue notes, float all public loans (Commonwealth, State, or municipal), act as banker for federal, State and municipal treasurers, and buy bullion and issue coin on behalf of the mints. When Labour came into office in 1910, this scheme was in the forefront of its programme; but Andrew Fisher, then prime minister and treasurer, during his visit to London in 1911 to attend the imperial conference of that year, arranged that his permanent advisers (who had accompanied him) should discuss the scheme very fully with the leading English and French banking authorities, and the bank instituted by the act of 1911 owed a great deal to those discussions. The note issue had already been provided for (see CURRENCY); otherwise the new bank was to be an ordinary bank of deposit, controlled by a single governor and carrying all Commonwealth accounts, but having attached to it a savings bank on the usual lines (see SAVINGS BANKS) operating through the federal post-offices. This involved the removal from those offices of the State savings banks, which had been allowed to use them since federation; Tasmania transferred its savings bank to the Commonwealth, but the other States maintained theirs in new buildings, having found the deposits useful as a fund from which State treasurers could borrow.

On 1 June 1912 Denison Miller (q.v.) assumed office as governor of the bank, and at once brought into existence the savings bank department, the Victorian branch being opened on 15 July 1912; by 13 January 1913 savings-bank operations were extended throughout the Commonwealth. On 20 January the bank itself was formally opened for general business at its head office in Sydney, with branches at the five other State capitals, Townsville in Queensland, Canberra (site of the future federal capital), and London. It had no capital resources save the credit of the Commonwealth; a sum of £10,000, borrowed from Commonwealth revenue to meet initial expenses, was repaid as soon as business commenced. A credit balance on general transactions was shown in 1914, and on the savings bank business in 1917. During the war-period (1914-8) the bank extended its activities to meet the special circumstances, and greatly increased both its prestige and its profits by its operations. Branches and agencies of the savings bank department were opened in the soldiers' training camps, on transport ships, and at the front; the service already established on the warships was extended; and the bank made itself responsible for financing Australian soldiers stranded abroad or taken prisoners of war. Moreover, all the general financial business of the Commonwealth was transacted through the bank. It floated government loans to an aggregate sum of £257,719,989; financed the pools for the marketing of primary produce; supplied the means for the purchase of 15 cargo steamers by the federal government; and arranged for secret shipments of gold from Australia on behalf of the Bank of England. After April 1916 it was also responsible for all banking business carried on in the occupied German territory of New Guinea. By June 1922 its profits had accumulated to the amount of £4,001,659, half of which was retained as a reserve fund, the other half becoming a 'redemption' fund against which debentures or stock may be issued if necessary. But by an act of 1923 all future allotments to the redemption fund will go to a sinking fund for the repayment of Commonwealth debt.

In December 1920 the issue of notes became a function of the Commonwealth Bank, being controlled, however, by a separate board of which the governor of the bank was chairman sitting alongside a treasury official and two outside financial experts. In the same month (December 1920) the Queensland government transferred the business of the Queensland Government Savings Bank to the Commonwealth Bank under an agreement ratified by the Queensland parliament.

In August 1924 a new Commonwealth Bank act improved the efficiency of the bank and provided means for making it a central bank. The act established a new board of directors, consisting of the governor of the bank, the secretary of the treasury, and six persons who are or have been actively engaged in agriculture, commerce, finance, or industry. The board controls not only general banking policy but also the issue of Australian notes. The bank's authorized capital is £20,000,000, of which £4,000,000 is paid up by means of a transfer from the reserve and redemption funds. With a view to helping the bank to become a central bank it is provided that, after a date to be proclaimed by the Commonwealth government, other banks are to settle balances between them by cheques drawn on the Commonwealth Bank.

Compositae, the most numerous and wide-ranging family of flowering plants, with a great variety of form and colour; 635 species are recorded from Australia. They are generally divided into two groups (1) Tubuliflorae, in which the disk florets, at least, are tubular, e.g. daisy and sunflower, and (2) Liguliflorae, in which all the florets are strap-shaped, e.g. dandelion. *Pterigeron* is an endemic genus; *P. liatroides*, an inland species, yields a delicious perfume. *Epaltes*, a small genus of herbs, has

two indigenous species; *E. australis*, a prostrate plant with dull brown, rayless flowers, usually frequents sour, ill-drained land. *Nablonium* is a genus of one species, *N. calyceroides*, a creeping herb usually growing in marshy places. It occurs on King Island and other islands in Bass Strait, and on the Tasmanian coast. *Erigeron*, a widespread genus (the fleabanes), contains the alpine herb *E. pappochromus* and the introduced weed *E. linifolius* (Cobblers' Pegs). *Raoulia eatipes* (Australian Edelweiss), is a dwarf alpine herb, which grows in low silvery tufts over considerable areas on Mount Kosciusko above the 5000-ft. line. *Ammobium alatum*, one of the 'Everlastings,' with chalk-white flowers, is a common garden plant. Its stems are bordered by a broad membranous wing. *Gnaphalodes uliginosum* forms dense mats on the western plains of New South Wales. The clusters of flower-heads are embedded in the woolly floral leaves. *Wedelia biflora*, a widely distributed coastal species, is usually found scrambling about the cliffs on rocky coasts. *Craspedia Richea*, chiefly found in grass-lands, has a number of small flower-heads collected in a semi-globular mass at the top of a common flower-stem. See BEDFORDIA, BIDENS, BRACHYCOME, CALOTIS, CASSINIA, CELMISIA, CENTIPEDA, COTULA, GNAPHALIUM, HELICHRYSUM, HELIPTERUM, OLEARIA, SENECIO.

Condamine, THOMAS DE LA (1797-1873), educated at the Royal Military College at Sandhurst (which he entered in 1814), was in 1825 commissioned lieutenant in the 57th regiment and in the next year joined Darling's staff as aide-de-camp and military secretary. Darling had a high opinion of his services, and in April 1827 made him collector of internal revenue—an appointment which was not confirmed in London, Bathurst having almost simultaneously directed another appointment. Condamine's hobby was education: he undertook gratuitously the management of the 'Carters Barracks,' a sort of elementary technical school, and was on the managing committee of the Female Factory, while as a private citizen he helped to found on 3 February 1826 a circulating library out of which grew in course of time the present public library of New South Wales. When Darling gave him the civilian appointment mentioned above, he applied for permission to resign from the army; when the appointment fell through, he withdrew the application and stayed in New South Wales as aide-de-camp, going back to England with Darling; he was then promoted captain, but assigned to no regiment, and placed on half-pay. He died in 1873.

Conder, CHARLES (1868-1909), born in London in 1868, and taken by his father to India while still an infant, was sent back in 1877 to England to be educated at Eastbourne, and at the age of 16 migrated to Sydney to enter the department of lands as an assistant surveyor. But his bent was wholly towards art; he studied in Sydney at the Royal Art Society's classes and in Melbourne at the National Gallery schools, besides learning much from association with fellow artists—B. E. Minns in Sydney and Tom Roberts and Arthur Streeton in Melbourne (see ART). For a time he was on the staff of the *Illustrated Sydney News*. In 1888 the Sydney gallery bought his 'Departure of the s.s. *Orient*,' exhibited in that year's show of the Art Society of New South Wales. In 1889 with Roberts and Streeton he exhibited a number of 'Sketches and Impressions' in Melbourne, and in 1890 he showed several pictures at the Victorian Artists' show. The generosity of an uncle then enabled him to return to London and settle to study in Paris, where in 1893 he was elected an associate of the Société Nationale des Beaux Arts. A few lithographs of his are known, a single dry-point, and a number of landscapes in oils, usually of seashores peopled by fashionable crowds; but the work he did best, by which he will be longest known, are delicate panels done in water-colour on silk, often shaped as fans. He was a member of the Société Nouvelle des Beaux Arts and of the International Society of Painters, and was honoured by having his work placed in the Luxembourg galleries. In 1907 he was incapacitated by severe illness, and died at Virginia Water near Windsor in England on 9 February 1909.

W.M.

Congregationalists. The history of Congregationalism in Australia is closely intertwined with that of two great missionary societies, the London Missionary Society and the Colonial Missionary Society, the first of which was founded in London in September 1795, its original name being simply 'The Missionary Society.' Its sole object was 'to spread the knowledge of Christ among heathen and other unenlightened nations.' The Colonial Missionary Society was also founded in London, largely under the influence of Thomas Binney and T. Q. Stow (q.v.) in 1836. Its object was to establish Congregational Churches in the British colonies. Between 1795 and 1836 the connection between the London Missionary Society and Congregationalism in Australia was particularly close, as is shown by a letter written from Parramatta, in New South Wales, on 29 August 1799 by William Henry, in which he states that 'in the beginning of August 1798, Mr. Cover and the writer began to preach in this colony in different places in the country, about the town of Parramatta.' 'Mr. Cover' was James Fleet Cover, one of a band of about 30 missionaries, who had been sent in the ship *Duff* to Tahiti, and some of whom afterwards settled in New South Wales. There is no evidence, however, that James Cover attempted to organize a Congregational Church, and very possibly such an attempt would have been frowned upon by the authorities of the day.

In 1801 Samuel Marsden (q.v.), the colonial chaplain, became the official correspondent and adviser of the London Missionary Society, especially with regard to the Tahiti mission. The London Missionary Society, though largely supported by Congregational funds, was not then (nor has it ever been since), strictly a Congregational society. Marsden afterwards came into collision with one of the missionaries, William Pascoe Crook (q.v.), concerning the celebration of the Lord's Supper. Crook it was who in August 1810 organized the first Congregational Church at his schoolhouse at the corner of Bligh and Hunter-streets, Sydney. This first Church consisted of five persons—Crook himself, three missionaries (Davies, Wilson and Tessier), and John Hosking. They had a church book with regular minutes, from which Crook quotes. Whether this movement survived we do not know. Probably it lapsed with the removal of its founder to Moorea in the South Seas in 1815, if not before. At any rate Daniel Tyerman and George Bennet, who visited Sydney in the interests of the London Missionary Society in 1824-25, reported that they could find 'no In-

dependent cause whatever' in that city. Crook returned to Sydney in 1830, and resumed his ministerial labours in the colony on 19 December in a chapel in Macquarie-street.

In 1828 there resided at Hobart in *Tasmania* a certain Henry Hopkins, an energetic, prosperous, generous man with a strong sense of responsibility combined with plenty of initiative. He had arrived in Hobart with his wife in 1822; they were Independents, and did not find in Hobart exactly what they needed in the way of religious life; they therefore asked the directors of the London Missionary Society to send out a minister. To do this was not within the Society's functions, so the letter was passed on to the authorities of Highbury College. Work in a distant outpost of the Empire appealed to a young man, Frederick Miller, who volunteered and, after being ordained, sailed for Hobart, arriving in September 1830. At first he preached at 'Dean's Rooms,' conducting his initial service on 17 October; these services he continued for 18 months, and a Church of nine members was formed in March 1832. In April the Brisbane-street chapel was opened for worship, and there Frederick Miller ministered until his death in 1862. The foundation-stone of a handsome memorial church was laid by Henry Hopkins on 16 August 1870. In 1832 Miller was joined by a fellow student of his at Highbury College, Charles Price (q.v.), who, after spending a few months in Launceston, proceeded to Sydney with the expectation of becoming the minister of the Pitt-street congregation. This expectation being disappointed he went to Carrington on Port Stephens, and acted as chaplain to the Australian Agricultural Company (q.v.) until March 1836; then he returned to Launceston and became pastor of the Tamar-street church, remaining a conspicuous and influential figure in the life of Tasmania until his death in 1891. In Hobart a second Church was established in Collins-street under the care of James Nesbit in 1836. In 1856 a fine church was built in Davey-street, and there for more than 50 years George Clarke (q.v.) exercised a distinguished ministry; he was a man of exceptional culture, and was closely identified with the Tasmanian university, being its second chancellor.

As already noted, the Colonial Missionary Society was formed in 1836, and with its assistance Joseph Beazley was sent as a home missionary to Tasmania, leaving the island after some years to settle in New South Wales. Under the auspices of the same society John West (q.v.) and Alexander Morison came to Tasmania in 1838. West, who settled in Launceston as pastor of a church in St. John's Square—(Christ Church, of which William Law was subsequently for many years minister), won a permanent place in Australian literature as the historian of Tasmania, and, coming to New South Wales, became editor of the *Sydney Morning Herald*. Morison took charge of the Pittwater district, where he preached at no less than 42 stations, and was instrumental in the erection of churches at Cambridge, Carlton and Richmond; he, too, ultimately felt the call of the mainland and settled in Melbourne in 1843 as minister of the Collins-street church. At the present time, in addition to the churches in Hobart and Launceston, Congregationalism is represented at Newtown, Bellerive and Lindisfarne (suburbs of Hobart), Geeveston, Franklin and Huonville in the south; at Latrobe, Don and Devonport in the north; and at Richmond, Kempton, Dover, Bream Creek and Taranna inland. The first council of the Tasmanian Union met in Hobart on 20 August 1867.

Congregationalism in *New South Wales* was first firmly established in 1828, when James Hayward and Robert Bourne, two of the Tahitian missionaries, with Ambrose Foss, a chemist, and Edward Hunt, inaugurated a movement in Sydney; the first service under these auspices was conducted by Charles Smith (a doctor of medicine as well as an ordained minister) at Hayward's house in Castlereagh-street on 22 November 1829. A site for a church was obtained in Druitt-street, but not used; a site on the western side of Pitt-street, on which the School of Arts now stands, was then procured, and the foundation-stone of the church laid by Hayward on 26 March 1830. (Later authorities give the date as 12 April—Easter Monday—but the contemporary evidence of the *Sydney Gazette* for 1 April would seem decisive.) This church was opened for worship on 15 February 1833, Charles Price and three Methodist ministers taking the chief part in the ceremonies. Price came over from Launceston at the desire of the congregation, their request for a minister from Highbury College having been unanswered for a long time; but on 21 March W. Jarrett arrived unexpectedly, and Price moved on to Port Stephens. Jarrett thus became the first permanent minister of the Pitt-street church, retaining the position until 27 April 1838. On 2 May 1833 a Church fellowship of 12 persons was formed under his leadership, consisting of W. Jarrett, J. Hayward, W. P. Crook, Hannah Crook, Richard Bourne, Ann Bourne, Sarah Stafford, Henrietta Stafford, Ambrose Foss, T. Hutchinson, Thomas Dunton and George Wagg. After Jarrett's departure the building was let for a while to John Dougall, an Irish Presbyterian minister.

A new era dawned with the arrival on 25 February 1840 of Dr. Ross, who had been sent out by the Colonial Missionary Society. His career had been chequered. He was educated for the ministry in Edinburgh, and, intending to go as a missionary to the Russian empire, qualified as a doctor of medicine; but soon after his arrival in Russia all foreign missionaries and Bible agents were driven from the country. In 1824 he returned to England and settled at Kidderminster, remaining there until 1836. His ministry of nearly 12 years in Sydney was successful and widely influential. He gathered round him men of exceptional quality, such as George Allen, Ambrose Foss, David Jones, Joseph Thompson, Robert Garrett and John Fairfax; and under his capable leadership the denomination began steadily to expand. In 1841 a church erected at South Head, towards which W. P. Crook had raised many subscriptions—a stone building with a chimney, standing near the Macquarie lighthouse on the site of the present fire station—was opened by Dr. Ross. Edward Lancelot Threlkeld, who had been a missionary in Tahiti and to the aborigines at Lake Macquarie, became its pastor, remaining in charge until in 1845 he moved to the Mariners' Church, Sydney; here he ministered until his death in 1859. In 1841, also, was laid the foundation-stone of a new church in Pitt-street, on the site of the church now existing; the ceremony was performed by Dr. Ross on 29 January. Owing to commercial depression there was much delay in the building, but it was ultimately opened for worship on 1 January 1846. At Redfern in September 1847 a fellowship was formed, and a building opened in October. J.

Beazley, from Tasmania, was the first in a succession of able ministers including W. Slatyer, George Campbell and Frederick Binns.

In 1853 William Slatyer made an effort to start work in Bathurst; disappointed there, he returned to Sydney and initiated services in a room in the Happy Vale hotel at Surry Hills. Hence arose the Bourke-street Church; a fellowship was formed in 1855, and the church building opened the same year. The year 1854 was a busy one. A Church was formed at West Maitland, under the ministry of John Waraker, who had arrived in New South Wales in 1851; the church building was opened in 1858. In 1854, too, George Charter settled at Petersham, moving later on to Wollongong; and the local Churches were visited by J. F. Poore, a man of great energy and enthusiasm. Work at Newtown, a suburb of Sydney, was commenced in 1855 by S. C. Kent, and Churches were formed at Petersham in 1863 and at Parramatta in 1870. At present Congregationalism has about 100 preaching stations in New South Wales.

The central church in Pitt-street was after Dr. Ross's death served by W. Cuthbertson, John Graham, James Jefferis (q.v.) and others; Nicholas J. Cocks took charge in 1907, but died in January 1925, and was succeeded by Thomas E. Ruth. In 1864 Camden College was established both as a boys' school and as a theological college. Its home was a property at Newtown which had belonged to Thomas Holt, M.L.A., and had borne the name 'Camden Villa.' Holt sold it to the denomination for £4000 (about half its value). Josiah Mullens was the first secretary of the college, John Fairfax the first treasurer, and S. C. Kent the first principal. In 1872 J. G. Fraser, M.A., was appointed warden, and held the office until 1909. He was a man of great ability, strong personality, and vast and accurate learning. With these gifts were combined patience, tact, wisdom and capacity for teaching. Through his students (some of them men of real distinction) he exerted a far-reaching influence on the religious life of Australia. He was succeeded in 1910 by the present warden, G. W. Thatcher, M.A., B.D.

In 1866 a Congregational Union was formed, which was incorporated in 1882. In 1903 a home mission board was formed, under W. L. Patison.

Behind *Victorian* Congregationalism, as behind Tasmanian, stands the beneficent figure of Henry Hopkins of Hobart. He visited the infant settlement at Port Phillip in 1837, and, struck by its possibilities, asked the Colonial Missionary Society to send a minister thither, at the same time forwarding a sum of money to cover his expenses. In response to his appeal William Waterfield reached Melbourne on 22 May 1838. At first services were held at John Pascoe Fawkner's public-house. A fellowship was formed in 1839. By a strange lapse from the Congregational principle of 'No state aid to religion' an application was made to the Sydney authorities for a grant of land; two acres were given, at the corner of Collins- and Russell-streets, and here the foundation-stone of a church was laid by Henry Hopkins on 6 September. The opening ceremony took place on 15 January 1841. Twenty-five years later this building was replaced by the existing structure. The Collins-street church was the first permanent building for public worship in Melbourne. For 11 years after Waterfield's arrival it was the only one the denomination possessed. He left for Tasmania in 1843, and was succeeded by Alexander Morison, whose work in Tasmania has already been noticed. The year was marked by the formation of the Port Phillip Colonial Missionary and Christian Instruction Society, whose aims were noble, though it failed to obtain workers and soon died out. In 1849, however, the population of the settlement having greatly increased, ministers began to arrive, among them B. Cuzens in 1849 and Thomas Odell in 1850; and between 1849 and 1854 11 new 'causes' were commenced —three in Geelong, the rest in Lonsdale-street (Melbourne), Prahran, Kyneton, Collingwood, Richmond, Brighton, St. Kilda, and White Hills near Bendigo. Since that time the denomination has developed until now it possesses about 90 churches and preaching places in town and country.

In 1854 a great impulse was given to the work in Victoria by the arrival of Richard Fletcher, J. F. Poore and Edwin Day, all three exceedingly able men, who were induced by the Colonial Missionary Society to migrate to Victoria, the Society becoming responsible for travelling expenses and stipends. They were designated 'Professor Fletcher, Evangelist Poore, and Pastor Day,' appropriate titles, happily suggesting the parts they were expected to play. A Congregational Union constituted in Melbourne on 8 June 1852 having lapsed, the existing one was formed on 1 March 1860. In February 1855 there met in Melbourne under the chairmanship of T. Q. Stow (q.v.) an intercolonial conference of two ministers from New South Wales, two from Tasmania, two from South Australia and eight from Victoria, the lay delegates including J. Fairfax, Ambrose Foss and Henry Hopkins. Other conferences were held at Sydney in February 1857, and at Adelaide in November 1859.

In 1861 the Congregational College of Victoria was established for the training of ministers. For many years Alexander Gosman, D.D., was its principal; he was a vigorous, independent and fearless thinker and speaker, and in addition to his academic work exerted a wide public influence. Sympathetic with the aspirations of the masses for better conditions, he was entrusted with the chairmanship of the shirt-makers' wages board—a unique honour for a clergyman.

The planting of Congregationalism in *South Australia* was almost coincident with the planting of the colony, and the two grew up together. In October 1837 T. Q. Stow (q.v.) reached Adelaide in the *Hartley*, and with characteristic energy began work at once. A service, at which Governor Hindmarsh was present, was held in a tent, and a Church fellowship of 11 persons was immediately formed, including T. Q. Stow, Robert Tod, John J. Barclay, William Finlayson, Edward Webb, James Wright and James Harrington. The first church building was made of pine logs thatched with reeds; a substantial building in Freeman-street was opened on 1 November 1840; the Stow Memorial church in Flinders-street (in which, of course, Stow himself never ministered) was dedicated to Divine worship on 12 April 1867. Stow's successor was C. W. Evan, a man of great culture, who came to Adelaide in 1855 in search of health. He resigned in 1871 and died in 1876. In March 1876 W. R. Fletcher, a man of great natural ability, sedulously cultivated, began a ministry of 14 years' duration, and his successor Joseph Robertson also served a 14 years' term in 1890-1904.

The second Church to be formed in the city, at Hindmarsh Square, dates from 1851. F. W. Cox, a man of singular sagacity, arrived in 1857 and was for 40 years its pastor. In the Brougham Place Church at North Adelaide James Jefferis

(q.v.) swayed the life of the city. It was formed on 20 October 1859, with about 20 members. Under Jefferis's robust leadership this number rapidly increased, and its vigour has been shown by the production of daughter Churches at College Park, Medindie and Crafer's Park. Services were started at Hindmarsh (not to be confused with Hindmarsh Square) in 1838, and a fellowship was formed in 1849. Clayton Church at Kensington dates from 1854, Glenelg from 1863 (services having been commenced there in 1847), and Port Adelaide from 1849; here for many years J. C. Kirby fulfilled a vigorous and effective ministry. The Congregational Union was formed in 1850, and incorporated in September 1877: it now includes about 80 churches and preaching stations.

South Australian Congregationalism has been singularly fortunate not only in its ministers, but it its laymen, such as William Peacock, who claimed to have a brick in every church in the colony; John Howard Angas, son of George Fife Angas (q.v.); and W. Parkin, the munificent founder of the Parkin college and the Parkin mission. The Parkin college is a well-endowed institution for the training of Congregational ministers; its first principal was L. D. Bevan (q.v.), who was followed by E. S. Kirk. The Parkin mission exists to give on Christmas Day every year five pounds each to 20 poor widows, and to pay the stipend of 'missionaries of the Congregational denominations.' In 1858 the great London preacher, Thomas Binney, paid a highly stimulating visit to South Australia.

Congregationalism in *Queensland* antedates by ten years the separation of the colony from New South Wales. In 1849 a little company of devout men and women at Ipswich used to meet for worship, and such a group is in essentials a Congregational Church. Of this Ipswich group a schoolmaster named Welsh acted as lay-pastor until nearly 1853. Meanwhile a Baptist minister, Thomas Deacon, arrived in 1850, a congregation gathered round him (at first in the court-house, then in a cottage adapted for the purpose of worship), and it was decided to form a 'United Congregational Church,' which would include both Baptists and Independents. A fellowship was formed, consisting of 12 persons. In 1854 Deacon resigned, the name was changed to 'Congregational Church,' and negotiations were opened with the Colonial Missionary Society, with the result that before the year's end Edward Griffith was sent out as pastor. A church was opened, free of debt, on 11 March 1855. In 1856 an exchange was arranged by the Congregational Missionary Society of New South Wales between Griffith and J. T. Waraker of West Maitland, who remained in Ipswich for about three years and a half; his aggressive policy of starting branch Churches so characterized the Ipswich Church in later years that Ipswich has become a sort of Congregational diocese, a mother Church sitting in the midst of her numerous daughters. In Brisbane in the early days Independents, Baptists and Presbyterians formed a 'United Evangelical Church,' managed (as such a Church must necessarily be) on Congregational principles. The Colonial Missionary Society, aware of the approaching separation of Queensland from New South Wales, sent out George Wight to promote Congregational work. He preached at first in a 'rickety loft, reached by a rickety trap ladder,' and received a visit of encouragement from Thomas Binney. A church at the corner of Wharf- and Adelaide-streets was completed by 10 June 1860, in which year E. Griffith (father of the late chief justice of Australia) became the pastor; he retained the office for 30 years. Wharf-street was also a prolific mother of Churches—Goodna (1863), South Brisbane (1865), Oxley (1871), Redcliffe (1880), O'Connell Town and Bowen Hills (1887) and Milton (1891). In Toowoomba J. T. Waraker laboured for 24 years. In Rockhampton the work was begun in 1861 by Samuel Savage. The Colonial Missionary Society at one time was accustomed to grant £300 a year to the work in Queensland.

The Congregational Union dates from 15 October 1861. It now includes about 50 churches and preaching stations. There is a college for the training of ministers; a college house was opened at Annerley on 24 March 1923, the gift of Frederick Marsden, with F. North as principal.

Although *Western Australia* was founded in 1829, Thomas Johnston reported in 1883 that there were only three Congregational Churches in the colony. Since that time a vigorous forward policy has been pursued, for which Trinity Church, Perth, and W. T. Kench, its capable minister for many years, are largely responsible, so that now the Congregational Union in the State includes about 70 churches and preaching stations. Here, as elsewhere, the Colonial Missionary Society has been helpful, having contributed up to 1903 about £5200 towards home mission work. In 1845 Henry Trigg first held services in his own house in Perth. In 1846 a small chapel was erected, where for years he preached gratuitously. When application was at last made to the Colonial Missionary Society for a minister, J. F. Leonard came out in 1851, but after three years moved to Gawler in South Australia. In 1862 the Colonial Missionary Society sent out another minister, J. M. Innes, who laboured in Perth for six years (a new church being erected during his pastorate), and then joined the Presbyterians. Then followed D. Meadowcroft, during whose time a manse was built. Bunbury Church, like Trinity Church, Perth, owes its initiation to a consecrated layman, John Allnutt, who in 1848 gathered a few people together for the reading and exposition of the Scriptures at Australind, about seven miles from Bunbury. Out of this grew a similar movement in Bunbury, where a small building was erected in 1855. Here, as well as at Australind, Allnutt continued to labour until his death in 1864. At Fremantle in 1851 a small religious society was formed and occasionally visited by Henry Trigg. In 1853, in response to an appeal to the Colonial Missionary Society, J. Johnston came to Fremantle; a small chapel was erected in 1854; then came a manse, and in 1877 a church with accommodation for 500 persons. Johnston had been for 11 years a missionary in Tahiti, so that our story both opens and closes with the London Missionary Society and its work in the South Seas. Fittingly, therefore, Australian Congregationalism has taken a great interest in the work of this Society and has contributed largely to it in both money and consecrated personalities.

The Australasian Union. In Congregationalism there is a strong strain of individualism, but also a strong instinct for fellowship. Hence arose both local groups, the individual Churches, and the combination of these into unions, which are found in every State of the Commonwealth. Quite early there manifested itself a craving for a wider union still, from which sprang the intercolonial conferences at Melbourne in 1855, at Sydney in 1857 and at Adelaide in 1859. Jubilee celebrations were held in Hobart in 1880, in Syd-

ney in 1883, in Adelaide in 1887, in Melbourne in 1888, and in Brisbane in 1903. It was at the Brisbane meetings that the Congregational Union of Australia and New Zealand, constituted at Melbourne in 1888, was revived. A. J. Griffith, M.A., was the energetic secretary for more than 16 years. To his devotion and tenacity of purpose the present strength of the movement is largely due.

Church Union. Congregationalism in Australia is sympathetic towards the idea of organic union between the Methodist, Presbyterian, and Congregational denominations. This was emphatically shown by a vote taken at the eighth triennial assembly of the Australasian Union, held at Sydney in 1922, when 78 voted in favour of union and nine against. Indeed, the opposition of the nine was not to the general idea of union, but to its consummation on a basis of doctrine and polity about which they entertained doubts and scruples.

Statistics. In 1922 the members of Congregational Churches in Australia numbered 21,654; the Sunday-school scholars 31,993; and the churches and preaching stations 497. These figures, which were given at the Australasian Union meetings in 1922, possibly include New Zealand.

F.V.P.

Conolly, PHILIP (1786-1839), born in Kildare county, Ireland, in 1786, trained for the priesthood, and engaged for some years in parochial work in the diocese of Kildare and Leighlin, volunteered in 1819 for the Catholic mission to Australia, and with John Joseph Therry (q.v.) sailed for Port Jackson in the *Janus* from Cork on 5 December. His appointment was official as well as ecclesiastical; he ranked as a government chaplain with pay of £100 a year. Reaching Sydney on 3 May 1820, the two priests set to work to organize the mission, which at the time was concerned to a large extent with convicts belonging to their Church who had for many years been left without religious ministrations. Although Father Conolly was the senior priest and nominal head of the mission, Father Therry was so much the more forcible character that the work in Sydney became entirely his, and will be narrated under his name; Father Conolly, finding their temperaments incompatible, in March 1821 migrated to Hobart. Accounts of his career in Tasmania have hitherto been based mainly on a report made by Father Ullathorne in 1833, when Father Conolly had been working for 12 years among small and scattered congregations and was a sick and worn-out man. Recently published official records (*H.R.A.* III. iv, v.) show, however, that the earlier years at least of his term were more successful than Ullathorne knew. He appears as a friendly mediator between Sorell and aggrieved settlers, and in 1824-6 was commended by Sorell, Arthur, Bathurst, and Dr. Poynter for satisfactory work. Arthur was especially loud in his praise, and on 1 February 1826 strongly recommended the doubling of his pay —which Bathurst coldly refused as inconsistent with the rate paid to other priests. In 1824-5 a curious episode disturbed his peace; Father Samuel Coote, who had in 1823 volunteered to join him in Tasmania as an assistant, claimed on arrival at Hobart to supersede him as official chaplain, and Arthur had some difficulty in getting rid of the intruder. Coote in the correspondence betrays himself as evasive and intriguing, and it may have been the local quarrels arising out of this episode (for Coote evidently gained the support of some Catholics there) that took the heart out of Conolly's ministrations, and brought about the negligence described by Ullathorne in 1833. Coote, whose conduct was severely condemned by Dr. Poynter, had left Tasmania for England in 1826, but ill-feeling often lasts far beyond the removal of its immediate cause.

From 1826, when he was still in favour with both official and ecclesiastical authorities, to 1833, when Ullathorne found religion in Tasmania 'in a state of complete decline,' there is no published record of Father Conolly's doings; but when Bishop Polding arrived in 1835, he was past work and impracticable. He claimed as his private property the land on which the chapel was built—a claim legally correct, since Sorell had made the grant to Conolly personally on the ground that he had brought capital (actually £14) into the colony, but ecclesiastically wrong, since the land had been dedicated by Conolly himself to Church uses. He even issued a writ against Dr. Polding, and had him arrested; this extravagance alienated the last of his friends, and he was superseded without trouble, at first by Father Watkins, then (in April 1838) by Father Therry. The recalcitrant priest was, however, ageing fast, and mellowing as he aged; he was reconciled to Father Therry and to the bishop, and died on 3 August 1839 in full communion with his Church.

E.M.O'B.

Conospermum, a genus of the family Proteaceae, consisting of shrubs endemic in Australia, and most of them in Western Australia. The flowers are blue, lilac, pink, or white in short dense spikes; corolla-tube either straight with 4 equal spreading lobes, or 2-lipped, the upper lip broad and concave, the lower one with 3 narrow lobes; stamens inserted in the swollen base of the tube or the concave base of the lobes; fruit a small obconical nut, with a broad, flat or concave apex covered with long silky hairs; leaves entire. Several species are known as 'smoke-bushes,' their densely crowded spikes of woolly grey and white flowers looking, at a distance, like smoke. Grazing animals browse with avidity on the downy flower-spikes, rejecting the foliage, so that the plants are not destroyed by excessive cropping. *C. tenuifolium,* a prostrate plant with wiry, grass-like leaves and pretty bluish flowers, is endemic in New South Wales.

Constitutions, State and Federal.

The constitutional development of Australia provides instances of the main types of government in British communities, from the earliest and most dependent stage of the crown colony to that of the adult and autonomous State or dominion.

From 1788 to 1823 the settlement in New South Wales was a crown colony of the extreme type, the governor having practically absolute power; the administrative officers also were military or naval men, not civilians. Until 1825 the governor's commission gave him control over all Australia east of 135°E. long., including Tasmania and the adjacent Pacific islands between 10° 37′ and 43° 39′ S. lat. New Zealand was not specifically mentioned, but early governors issued proclamations affecting that country, and thus demonstrated that they considered it within the ambit of their jurisdiction. In New South Wales the governor at the outset exercised legislative, administrative, and judicial functions. There was no other legislative body, hence his proclamations had temporarily the force of law—they needed, however, confirmation by the colonial office to make them permanently valid. He was

assisted in the administration by a few officials, including a lieutenant-governor and a judge-advocate, but they were subject to him and could be dismissed by him. The financial administration, such as it was, was in his hands. And, though courts of justice were established, he had the nomination of judges and magistrates, was himself the court of appeal, and could order summary punishment of offenders, or pardon them at his will. 'He was,' says Rusden, 'not only vicegerent, charged with the awful power over life and death; on him fell also the care of the infant settlement in its most trivial affairs. For him it would be to negotiate bills in England, to influence shipments of foods and necessaries, to distribute land, to foster agriculture, to settle disputes. He was himself the local Court of Appeal. From no petty trifle could he escape, from no high duty could he shrink.' The settlement was of a military character; the court of criminal jurisdiction was a court martial, in that it consisted of the judge-advocate and six naval or military officers. The civil court consisted of the judge-advocate and two inhabitants, in practice a military officer and either a civilian or a naval officer.

In 1814 the civil and criminal courts were placed under separate authorities, and the civil court was developed into a supreme court and a governor's court. The supreme court, consisting of a judge appointed by the colonial office and two magistrates appointed by the governor, heard cases in which sums greater than £50 were involved. Appeals were still heard by the governor and judge-advocate for amounts between £300 and £3000; where amounts beyond the higher limit were involved, an appeal lay to the privy council in England. The governor's court, a continuation of the original civil court, consisted of the judge-advocate and two inhabitants, but its jurisdiction was restricted to cases involving not more than £50. The system was still defective, both for lack of a civilian jury system, and because the judge-advocate as judge had to give decisions in cases in which as advocate he had initiated the prosecution.

New South Wales.—The first four governors of New South Wales were naval officers. The constant quarrels of all except Phillip with the local military authorities, and their inability to suppress the illicit rum trade then rampant in the colony, forced in 1809 the appointment of a military officer, Colonel Lachlan Macquarie. His autocratic administration, together with his patronage of emancipists (q.v.) resulted in the appointment of J. T. Bigge (q.v.) as commissioner to investigate and report on the colonial administration; and Bigge's report (made in 1822), following on the opportune publication of W. C. Wentworth's book on New South Wales in 1819, led to constitutional concessions in 1823, when the New South Wales judicature act was passed. This act constituted the first breach in the system of gubernatorial autocracy. A legislative council was created, to consist of five, six or seven members appointed by the governor. In December 1825 the councillors were the lieutenant-governor, the chief justice, the archdeacon, the colonial secretary and three civilians—John Macarthur, Robert Campbell and Charles Throsby. The four official members of the legislative council also constituted the executive council, which formally came into existence on 20 December 1825. The governor presided over the legislative council, and initiated legislation. He still had power to issue ordinances contrary to the will of the majority of council, so long as one councillor supported him; in the event of rebellion (or even threatened rebellion) his will prevailed against a unanimous council, though no ordinance could be issued before submission to the council. All legislative proposals, before they were considered by the council, were submitted to the chief justice, who determined whether they were compatible with English law. The British parliament could revise all colonial laws and ordinances, and, finally, the crown could exercise its right of veto. Consequently the concessions made in 1823 were much restricted, the council having little power beyond the right of taxation and of free criticism; and against the latter the official or nominee character of its personnel was a safeguard. No tax or duty could be levied except for local purposes—that is, the colonies could not be exploited for the benefit of the Imperial revenue.

The same act provided further judicial reforms. Francis Forbes was appointed the first chief justice, and the offices of judge and advocate were separated. The supreme court was to consist of two or three judges. Limited provision was made for a civilian jury in civil cases to the extent that if the parties to a suit so desired, it might be heard before a jury of 12 men each possessing at least 50 acres of freehold or dwelling worth £300 or upwards. Criminal cases were still court-martialled before a judge and seven military or naval officers; though Chief Justice Forbes, whose sympathies were with the emancipists, held that by reason of a verbal defect in the act jurors could be empanelled at quarter sessions. The right of challenging jurymen was recognized. In addition to quarter sessions, which could be held at such times as the governor appointed, local courts of requests might also be instituted to hear cases for claims up to £10. An important provision of the act permitted the separation of Tasmania from New South Wales whenever the colonial office thought fit.

The original intention of the British parliament was that the act of 1823 should remain in force till 1 July 1827; but by a special act it was continued in operation until 25 July 1828, when the provisions of the act of 1823 were slightly amended. The legislative council was numerically strengthened; it was to consist of from 10 to 15 members, thus providing for a greater proportion of non-official members. The governor was directed to preside at its meetings, and was given a casting vote. The veto of the chief justice on proposed legislation was abolished, but the supreme court was to advise the governor, within 14 days of the passing of an act, if it were in any way repugnant to British law. Furthermore the governor was no longer allowed to issue ordinances against the wish of his council. Regarding judicial matters the intermediate court of appeal, consisting of the governor and the chief justice, was abolished, and all appeals from the supreme court went direct to the privy council in England. Trial by jury, which under the act of 1823 could not be granted unless both parties to a case asked for it, was in 1828 made grantable by the supreme court on the application of either party. In 1832 trial by jury was made available in cases involving certain crimes and misdemeanours, and emancipists with freehold worth £300 or an income of £30 became qualified to serve as jurors. In 1839 military juries were dispensed with, and all crimes and offences were tried before a jury of 12 citizens.

With the increase in the number of free settlers, the raising of public revenue within the colony, and the cessation of transportation in 1840, the question of giving New South Wales a larger endowment of political freedom became urgent. Largely through the agitation kept alive by Wentworth and his friends in the Australian Patriotic Association, an 'Act for the Government of New South Wales and Van Diemen's Land' was passed in 1842. The legislative council of New South Wales was henceforth to consist of 36 members, 12 nominated by the governor, the rest to be elected by owners of freehold worth £200 and householders paying £20 (lowered to £10 in 1850). The district of Port Phillip (which had in 1841 unsuccessfully petitioned for separation) returned five members, the town of Melbourne, one, and the town of Sydney, two. With any change in the numerical strength of the council, the ratio of one-third and two-thirds between the nominated and the elected members was to be observed. Of the 12 nominees six at least were to be non-officials. Councillors were to possess freehold worth £2000 or returning £100 in annual income. A speaker was to be elected from and by the members (Alexander Macleay, q.v., was the first). The governor, who thus ceased to preside over meetings of the council, could still instruct it to consider measures and amendments, but it obtained the right to initiate legislation without his intervention. Its maximum lifetime was five years, though it might be dissolved sooner; it must be summoned for at least one session each year. It was also given the power of imposing customs duties, but was not allowed to fix differential rates as between one country and another; duties were collected by officers responsible to the home authorities, and the appropriation of revenue was made on the governor's recommendation.

This act was a further step away from autocracy and towards democracy. The governor's constitutional influence was considerably weakened; but he was still his own prime minister, appointed and dismissed at pleasure the heads of departments, could dispose of crown lands and the proceeds from the sale thereof, introduce financial measures, exercise an independent control over the finances, and veto the council's measures. In short, executive officers were independent of the legislature, and the main tenet of the system of responsible government was thus unrecognized. The newly-constituted legislative council met for the first time on 1 August 1843.

The same act made provision for the establishment of district councils, to consist of from 8 to 21 members according as the population of the district varied from 7000 to 20,000 and upwards. In addition to the usual functions of a municipal body, these councils were to provide half the cost of police maintenance, though they had no control over the police. The governor could collect the amount, if necessary, by distress and sale of the property of district treasurers, councillors and inhabitants of the district. This scheme of local government provoked widespread opposition, and was never fully brought into operation, the whole of the police-fund being provided annually by vote of the legislative council from the general revenue.

Further dissatisfaction with Earl Grey's attempt to foist another local government scheme on the colonies, together with the desire of Port Phillip for separate political existence, resulted in an enquiry by a specially constituted committee of the privy council on trade and plantations. The outcome of its recommendations was the act of 1850 'for the better government of her Majesty's Australian colonies' (13 and 14 Vic. cap. 59), which provided for the erection of Port Phillip district into a separate colony, the establishment of legislative councils in Tasmania, South Australia, and Western Australia, and an increase of legislative powers for New South Wales, including the power to impose customs duties to take effect without awaiting the Queen's assent. The franchise was liberalized, freeholders of property worth £100 and householders paying a rental of £10 being enfranchised. But, as experience proved, the most important clause was that empowering the council to amend the constitution so as to provide for a bicameral legislature. The governor of New South Wales also received commissions as captain-general and governor-general of all the Australian possessions, and as governor of New South Wales, Tasmania, Victoria, and South Australia—the actual governors of the last three colonies being in name merely lieutenant-governors. This federal experiment was abandoned in 1861. District councils were rendered more acceptable by placing their establishment on a voluntary basis, and by relieving them of the expense of the police establishment.

Hitherto we have been dealing with the whole of eastern Australia. We now discuss the constitutional history of New South Wales within its present limits. Here the act of 1850 gave little satisfaction, because (1) the council's control over matters of revenue and expenditure was not yet complete, (2) the British government still interfered in appointments to colonial positions, and (3) the legislature still lacked control over the executive. A 'declaration and remonstrance' was in May 1851 drawn up by the legislative council at the instance of W. C. Wentworth, and forwarded to Downing-street. In reply Sir John Pakington, the new secretary for the colonies, encouraged the colonial council to draft a constitution for itself. Select committees in 1852 and 1853, with W. C. Wentworth as chairman, did so without delay, and an act to confer a constitution on New South Wales received the royal assent on 16 July 1855. By it a bicameral parliament was constituted, with an elected legislative assembly of 54 members in the first instance and a nominee legislative council of not fewer than 21 members; at least four-fifths of the councillors must be non-officials. The franchise was conferred on residents of six months' standing with freehold property worth £100, rent-payers of £10, and persons paying £40 a year for board and lodging. The duration of parliament was limited to 5 years. All appropriations of revenues, including proceeds from crown lands, were controlled by this legislature, the assembly determining both taxation and appropriation. Henceforth, therefore, ministers of the crown were responsible to the legislative assembly. Britain still forbade the levying of differential customs rates, but this embargo was finally lifted in 1873. The purity of justice was safeguarded in the usual way by the appointment of judges for life. The first parliament under the new constitution met on 22 May 1856 to elect a speaker, and was ceremonially opened on the 23rd with Stuart Donaldson as the first premier.

Since 1856 the following modifications in the constitution have been effected:—(1) In 1857 simple majorities of the assembly, instead of two-third majorities, were made sufficient to effect constitutional amendments. (2) In 1858 the secrecy of the ballot box was introduced. (3) In

1874 the duration of each parliament was limited to three years. (4) Manhood suffrage and the principle of 'one man one vote' were adopted in 1893. (5) The franchise was extended in 1902 to women, who, however, were debarred from entering parliament. (6) In 1912 provision was made for a second ballot; whenever more than two candidates were nominated, and the candidate at the top of the poll did not receive an absolute majority of the votes recorded, a second poll was taken between the two most favoured candidates. (7) In 1918 the State was broken up into 24 large electorates, each returning three or five members, and a system of preferential voting was adopted. At first it was necessary to vote (in order of preference) for all candidates indicated on the voting paper, but since 1921 it has been sufficient to vote only for the number of candidates to be elected. Electors absent from their electorates may vote at any polling-booth in the State, and postal voting is allowed to the ill and infirm. A casual vacancy occurring between two general elections is filled by the unsuccessful candidate next on the poll who represents the same party as the member vacating the seat; when no such candidate is available, the leader of the party concerned nominates the successor. Enrolment as an elector is compulsory, voting is not. The electorates are redistributed every nine years, or sooner if the government so directs. Since 1916 public servants have been allowed to stand for election without resigning their positions, though resignation must follow successful election. Women have been eligible for election since 1918, but up to the end of 1924 none had been elected.

The numerical strength of the assembly has varied. In 1856 it was 54; 72 in 1858; 108 in 1880, with provision for automatic increase as the population grew, so that in 1891 there were 141 members. In 1893 the number was reduced to 125, and in 1901 (after federation) to 90. Members of the assembly have been paid, since 1889, at the following rates:—from 1889 to 1912, £300 a year; in 1912 and onwards, £500; in 1920-21, £875; since 1922, £600. The premier receives £2000; attorney-general, £1600; other ministers, £1500; speaker, £1400; chairman of committees, £840. The members of the council, whose number is unlimited (there were 75 in 1924), are unremunerated, but the president receives £925 and the chairman of committees £500.

In 1788 New South Wales comprised all the continent east of the 135th meridian; in 1825 the boundary-line was shifted west to the 129th meridian, the present boundary of Western Australia and South Australia. In the same year Tasmania was constituted a separate colony; this had been provided for in the act of 1823. Western Australia was formally annexed in 1829, South Australia was carved out of New South Wales in 1836, Victoria in 1851, and Queensland in 1859. South Australia was enlarged in 1862 by the addition of the narrow strip between the 132nd and 129th meridians. In the same year the detached northern portion of New South Wales was divided, all east of the 138th meridian being handed over to Queensland; and in 1863 the remainder of this detached area, thenceforth to be known as the Northern Territory, was placed under the jurisdiction of South Australia, which in 1911 transferred it to the federal government. (See COLONIES, CREATION OR SEPARATION OF.)

TASMANIA.—From its settlement in 1803 to 1825 Tasmania was under the jurisdiction of the governor of New South Wales, with a lieutenant-governor acting under instructions. When separated in 1825 it was given its own legislative council, executive council, and supreme court, all on the New South Wales pattern. In 1850 it was granted a partially elected council, such as had been granted to the mother-colony in 1843. Responsible government was established in 1856. Tasmania's bicameral system of legislature varies from the normal type in that both council and assembly are elected. The council consists of 18 members, who must be at least 30 years old, elected by owners of freehold worth £10 a year, professional men, naval and military officers, and university graduates and associates. Three councillors retire annually, so that the council as a whole is never dissolved. The assembly of 30 members is elected by adult suffrage; the State is divided into five electorates, each returning six members, who are elected on a slightly modified Hare-Clark preferential system of voting. Members of both houses receive £300 a year, the premier £1200, other ministers £1000 each, and the president of the council and speaker of the assembly £500 each. A remarkable development of parliamentary government occurred in Tasmania on 1 December 1924, when the acting-governor (Sir Herbert Nicholls) on the advice of the crown law officers assented to the appropriation bill in the form in which it passed the house of assembly, ignoring amendments made in it by the legislative council. The colonial office, appealed to beforehand, merely assured the acting-governor that his action was not unconstitutional, responsibility resting on his ministers.

WESTERN AUSTRALIA.—The first British settlement on the western side of the continent was effected in 1826, when a military establishment was made at King George's Sound. Three years later a community of free settlers was founded at Perth with Stirling as lieutenant-governor. At first the governor was assisted by an executive council of four officials. In 1831 these five also constituted the legislative council, but eight years later four non-official members were added. An Imperial act of 1850 provided that the colony might establish a legislative council of the old two-thirds elected type; but this involved the cessation of grants from Britain and the assumption by the colonists of all the expenses of government. The price was too high, and no advantage was taken of the act until 1870. In 1867-8 the composition of the legislative council was altered to six nominated officials and six non-official members nominated by the governor, after election (on a free-manhood suffrage basis) by six districts into which the colony was divided. In 1870-89 the legislature was partially elective, 12 members being elected by owners of £50 of freehold and householders paying £10 yearly, and six being nominated by the governor. The paucity of population delayed the granting of bicameral responsible government till 1890. At first the council was nominated; from 1893 onwards it consisted of 21 members elected by freeholders, householders, lease and licence holders. The numbers have been altered from time to time: at present (1925) 30 councillors, each at least 30 years old, are returned by ten electorates for a period of six years, one-third retiring in rotation biennially. The assembly, which in 1893 had 33 members, now consists of 50 members returned by single-member electorates on a system of contingent or preferential voting. Since 1920 women have been eligible for election to either house, and one woman has been elected to the assembly.

Women have exercised the franchise since 1899. Members of the legislature receive £400 a year, the president of the council and speaker of the assembly receiving £700, the premier £1500 and other ministers £1300.

SOUTH AUSTRALIA.—For some time after the foundation of this colony in 1836 the control of land and the revenues from land were placed in the hands of a board of colonization commissioners, other matters being administered by the governor. In 1842, however, South Australia became a crown colony of the ordinary type, the governor controlling the whole administration with the aid of a nominee council of seven members, three officials and four non-official persons. The first council was called together in October 1843. The right to elect some members was granted in 1851, when a council of 24 members (16 elected, 8 nominated) was created. In 1856 responsible government under a bicameral legislature was established. The council consisted of 18 property-owners, each at least 30 years old, elected for 12 years, one-third of the number retiring every fourth year; in 1902 the term was reduced to six years, one half (nine members) retiring triennially. Since 1913 there have been 20 members elected by five districts. The first assembly consisted of 36 members from 12 electorates: in 1875 22 electorates returned 36 members, in 1882 26 returned 52, and from 1888 onwards the Northern Territory also elected two members. In 1902, after the accomplishment of federation, the numbers were reduced to 42 members for 13 districts. Since 1913 46 are elected from 19 constituencies. Between 1887 and 1921 members of the legislature received £200 a year, but on 1 December 1921 the amount was increased to £400: the president of the council and speaker of the assembly receive £800, and ministers divide £7750 between them. The assembly was based from the first on manhood suffrage, and after 1894 on universal adult suffrage, South Australia being the first colony to adopt woman suffrage. Since 1856 parliaments have been triennial. In case of a deadlock between the houses—i.e. should the council in two successive parliaments reject a measure sent up from the assembly—the governor may either dissolve both houses or make additional appointments to the council.

VICTORIA.—The settlement at Port Phillip was in 1843-51 represented in the partially elective legislative council of New South Wales, five members being elected by the district and one by Melbourne. The act of 1850 provided for the erection of Port Phillip into a separate colony, with its own legislature, and the issue of writs on 1 July 1851 for the election of a Victorian legislative council marked the separation. Provisional arrangements made by the New South Wales council constituted 16 electorates to return 20 members—three to represent Melbourne, two for Geelong, three for other towns, three for the settled districts of Bourke and Grant, five for intermadite districts, and four for pastoral districts; to these were added ten members nominated by the governor. In 1856 responsible government with a bicameral parliament was granted; the council (which was elected) consisted of 30 members, each at least 30 years old, possessing freehold to the value of £5000 or returning £500 per annum, members holding their seats for ten years. The 60 members of the assembly were elected for five years (after 1857 under manhood suffrage); they must possess a freehold worth at least £2000 or returning £200 yearly. The qualification for council electors was for many years high; but now an owner of freehold with a rental value of £10, a leaseholder or tenant paying £15 rent, university graduates and matriculated students, members of the legal, medical, ecclesiastical, and teaching professions, and officers of the army and navy are entitled to vote, and in 1909 the franchise was extended to women under the same conditions. The present council, which between 1856 and 1902 grew to 48 members, now consists of 34 members elected for six years from 17 districts, one half retiring triennially. A council elector may be enrolled in respect of residence for one district, and in respect of freehold property for another, but it is difficult for him to vote twice because of the size of the electoral districts; further, voting by post (which has been allowed since 1900) does not permit of a dual vote. The assembly consists of 65 members returned by single-member electorates under adult franchise. In 1903 the over-great influence of public servants with a vote led to their segregation from the residential constituencies: railway employees were given two representatives, and other public servants one in the assembly, and one representative in the council was assigned to the whole public service. The experiment proved unsatisfactory, and was abandoned in 1906. Preferential voting was adopted in 1911. Special provision has been made for a simultaneous dissolution of both houses when the council twice rejects a measure passed by the assembly in consecutive parliaments. The council may suggest amendments to appropriation bills at three stages: (1) when the bill is in committee, (2) in the report of committee, (3) during the third reading. The ministry is limited to eight members, not more than six being appointed from the assembly; not less than four must be members of one or other of the houses, so that it would be constitutional to have four non-members of parliament in the ministry—in actual practice this provision has been ignored. A minister who is a member of the assembly may attend council meetings to explain government measures, but cannot vote in that chamber. Members of the assembly are paid £500 a year, councillors since 1922 £200 a year; the president of the council receives £750, the speaker of the assembly £1000, the premier £1600, and other ministers £1200.

QUEENSLAND.—The 'Northern District' of New South Wales, which included the Moreton Bay and Darling Downs settlements and stretched as far south as Port Macquarie and the upper Hunter valley, was after 1843 an electoral district; but in 1851 Moreton Bay was sufficiently populated to be granted a member of its own, and by 1858 nine members represented districts north of the Clarence. On 6 June 1859 the colony of Queensland was constituted by letters patent, under authority of the acts of 1842 and 1855. The first Queensland parliament met on 22 May 1860. The constitution of the colony was based largely on that of New South Wales, with a nominated council and an elective assembly. The provisions of the New South Wales constitution act of 1853 (which provided for a nominated council and an elective assembly) remained in force in the new colony until 1867, when a separate constitution act was passed, chiefly as a consolidating measure. In 1886 Samuel Griffith passed a members' expenses act, thus laying the foundation for the payment of members act of 1889, which provided members with a salary of £300 per annum. Several attempts were made to reform the legislative council. In 1908 the legislature repealed a proviso necessitating a

two-thirds majority in each house for bills amending the constitution, and in the parliamentary bills referendum act provided for the submission to electors of any bill passed in two succeeding sessions by the assembly and rejected by the council. In 1915, 1916-17, and again in 1918 bills providing for the abolition of the legislative council were passed by the assembly but rejected by the council. In 1921, however, the act was passed, and came into operation in 1922. Since 1910 the assembly has consisted of 72 members, elected by single-member electorates on an adult suffrage basis. A modified system of preferential voting has been adopted. On 22 August 1922 members of the assembly were given the right to vote by proxy, so that a ministerial majority is never endangered by the absence of any of its members. Parliaments were quinquennial up to 1890, triennial since. Members receive £500 a year, the speaker £1000, the premier £1300, and other ministers £1000. Whereas in the other States members of parliament are given free passes over the State railways to enable them to visit their constituencies, in Queensland—where much of the travelling must be done by steamship or coach—members are reimbursed their travelling expenses.

THE COMMONWEALTH.—In 1901 the constitutions of all the Australian colonies were modified by removing certain powers from the ambit of each colonial legislature and entrusting them to a new legislature elected by the Australian people as a whole. The methods by which this change was accomplished, and the general history of the movement towards federation, are recounted under FEDERATION. The nation formed by thus uniting the populations of the six colonies was named 'The Commonwealth of Australia,' and the several colonies became 'States' of the Commonwealth. Its constitution may be examined under the following six headings:—(*a*) the executive, (*b*) the legislature, (*c*) the division of powers, (*d*) the judiciary, (*e*) provisions for amendment, (*f*) Imperial connections.

The Executive.—The federal executive power is vested in the sovereign of Great Britain, and is exercised by his representative the governor-general, who summons, prorogues, and dissolves parliament, may withhold his assent to bills whenever Imperial interests demand it, and at times of political crisis may exercise his own discretion whether to dissolve parliament or to select new advisers. In this respect he has actually greater powers than the King, who invariably acts in this matter as in all others on the advice of his ministers. Of late years this exercise of personal discretion has somewhat fallen into disuse, but it is not obsolete (see Keith's *Responsible Government in the Dominions*, pp. 180-211). In other matters the governor-general acts always on the advice of his ministers, who are collectively responsible to the federal lower house for their administration. Under the constitution act of 1900 a ministry must not consist of more than seven members, whose remuneration must not exceed £12,000 in all. But in 1915 and 1917 the maximum number was increased to nine and the remuneration to £15,300, of which the prime minister receives £2100. The executive at present includes a prime minister, treasurer, attorney-general, postmaster-general, vice-president of the executive council, and ministers for home and territories, defence, works and railways, and trade and customs. There are also two honorary ministers, who assist the more overburdened of the others.

The Legislature consists of the King (represented by the governor-general), the senate and the house of representatives. The senate is nominally the States house, in that the principle of the equality of States is recognized in the election of members. Each State, irrespective of its population, elects six representatives on a basis of manhood suffrage, the object being to safeguard the interests of the smaller States. They are elected for a term of six years, one half of their number retiring every three years—an attempt to secure continuity of policy and provide against sudden radical changes. For senatorial elections each State forms a single constituency. The house of representatives is based on the principle of equality of electors, members being allotted to each State in proportion to its population. The quota (number of electors whom each member should, approximately, represent), obtained by dividing the total population of the Commonwealth by twice the number of senators, is itself divided into the State population to ascertain the number of representatives for the respective States. Nevertheless, as no State may be represented by fewer than five members—and Western Australia would by mathematical calculation be entitled only to four, and Tasmania to three—the total strength of the house of representatives is 75 or somewhat more than twice the strength (36) of the senate; New South Wales sends 28 members, Victoria 20, Queensland 10, South Australia 7, Western Australia 5, and Tasmania 5. In addition, the Northern Territory sends a representative to the lower house, with power to participate in the debate but not to vote. The house of representatives is elected for three years at most; every qualified elector is also eligible as a candidate. The powers of the two houses are co-ordinate, except that bills appropriating revenue or imposing taxation must originate in the house of representatives. The senate has power to accept or reject *in toto* such measures, but not to amend them, though it may 'suggest' amendments. In case of a deadlock between the two houses—that is, when the senate has twice rejected or insisted on hostile amendments in a measure that has passed the house of representatives—the governor-general may dissolve the two houses if an election is not due within six months. If after the subsequent election the difference between the two chambers continues, a joint sitting is held, and the numerical superiority of the house of representatives over the senate gives the former an overwhelming predominance. Members of both houses receive £1000 a year, the president of the senate £1900, and the speaker of the house of representatives £1900.

Division of Powers.—The federal parliament is empowered to make laws with regard to certain specified matters, namely, foreign and inter-State trade and commerce (but not intra-State trade), customs and excise, bounties on exports and goods produced within the Commonwealth, borrowing on Commonwealth credit, postal, telegraphic and telephonic matters, defence, lighthouses, meteorological and astronomical observations, quarantine, fisheries beyond territorial limits, census and statistics, banking and insurance, weights and measures, exchange and promissory notes, bankruptcy, copyrights, naturalization, marriage and divorce, foreign corporations, invalid and old age pensions, civil and criminal processes, immigration and emigration, external affairs, the Pacific islands, railways for defence purposes, conciliation and arbitration in disputes extending beyond the limits of a single State.

The federal authorities must allow absolute free trade between the States, and customs duties must be uniform throughout the Commonwealth.

The State legislatures still exercise powers not specifically enumerated as federal in the constitution. They still control public lands and works, intra-State trade and industry, justice, the railways, education, and local government. The States cannot raise military or naval forces, or coin money, or tax federal property; the Commonwealth cannot tax State property. In the imposition of customs provision was originally made (see BRADDON CLAUSE) for the return of three-quarters of the revenue to the States. Since 1910 the States have received, in lieu of this, 25 shillings per head of population. Provision is made in the constitution for the transfer of State debts to the Commonwealth, but this has not yet taken place. Trade and commerce were placed under an inter-State commission in 1912.

The Judiciary.—The federal judicial power is exercised by a high court consisting of a chief justice and several puisne judges (at first two and later six), who are rendered independent of political pressure by being appointed for life at a salary fixed and irreducible during their term of office. It has appellate jurisdiction (1) against the decision of any of its own justices exercising original jurisdiction, (2) from other federal courts, the supreme courts of the States and other State courts, (3) from the inter-State commission. The high court's decision is final, except that appeal may be made to the King in council when the King (i.e. the judicial committee of the privy council) or high court itself gives its sanction. It has also original jurisdiction in matters (1) arising under a treaty, (2) affecting consuls or foreign representatives, (3) in which the Commonwealth sues or is sued, (4) between States, or residents of different States, or a State and a resident of another State. It is also the 'guardian of the constitution' and tests the validity of Commonwealth or State laws by reference to the federal constitution whenever a State or individual appeals for such a decision.

Amendment of the Constitution.—The federal constitution is of the 'rigid' type—that is, it cannot be amended by any ordinary process of legislation. Section 128 ordains a method of amendment much hedged in by restrictions. In the first place an amending act must be passed by an absolute majority of each house of parliament. If either house refuses to accept unaltered an amending bill twice passed by an absolute majority of the other house, the bill so passed is treated as if it were an act. In the second place, the act (or bill) must be submitted by referendum to the electors not less than two or more than six months after being passed as aforesaid. In the third place, the referred proposal must be accepted by (*a*) a majority of all the electors voting, (*b*) a majority of the States. Furthermore, any amendment affecting the provisions of the constitution in regard to any particular State (e.g. altering its proportionate representation, or affecting its territorial limits) must also be accepted by a majority of electors voting in the State affected.

Imperial Connection.—The Commonwealth and the States are connected with the British Empire by means of the following links:—(1) The governor-general is appointed by the British government. (2) The governor-general in the first instance, and the King (even when his representative has given assent to a bill) have the right of veto. (3) State governors are appointed by the British government, thus indicating the greater independence of Australian States as compared with Canadian provinces. (4) The amending power lies with the parliament and people of Australia, but the home parliament has a nominal right to amend. (5) Appeals may be made from the high court to the privy council. (6) Great Britain still undertakes the ultimate responsibility of defence and control of foreign policy, though of late years the powers of the Dominions in these respects have somewhat expanded. (7) Australian parliaments cannot annex territory unless the crown specially delegates to them the power to do so. (8) The British parliament claims the right to make laws binding on the whole Empire, but on all matters of common concern the Dominions are consulted, principally through the medium of Imperial conferences (q.v.).

K.R.C.

Convicts. This article, which is concerned solely with the convict after his landing in Australia, should be read in conjunction with that on TRANSPORTATION, which deals with his sentence, term of imprisonment in England, and passage out.

By two orders-in-council dated 6 December 1786 the eastern coast of Australia, and the adjacent islands, were appointed places to which offenders could be transported oversea from Britain; and it was with the despatch of 696 convicts in the 'First Fleet' (q.v.) in 1787 that the English occupation of Australia was initiated. Despite protests which grew stronger and stronger as years went by, and had at least the result of restricting the area in which this 'dumping' was permitted, the process was continued until 1867. During that period the total number of persons sent under sentence to Australian shores amounted to 160,663, of whom New South Wales between 1788 and 1841 received 83,290, and Tasmania (1803-1852) 67,655; Western Australia in 1850-1867 received 9718, all males. So long as convict labour was felt to be an economic necessity, the reception of the transported had been taken as a matter of course; but, when the colonies had developed into large and self-sufficing communities with a large free population, and had become jealous of their standing and reputation in the civilized world, the system could no longer be tolerated.

Of the 696 convicts who formed the first contingent to New South Wales, 192 were women. During the whole transportation period, there was a similar (or even a greater) disproportion of the sexes. Of about 100,000 transported up to 1836 only 13,000 were females. This fact not only accounts for the low birthrate during the early period, but has an important bearing upon the amount of 'convict blood' inherited by later generations. The suspicion of a 'taint' is in any case grossly exaggerated by those who underestimate both the number of free settlers even in convict days, and, still more, the overwhelming influx of immigrants of a high type who have arrived since the system became part of ancient and half-forgotten history. Thus, in New South Wales alone, during the years 1861-1915 there arrived some 443,000 immigrants; indeed, except for internal migrations, most of the present States have been almost entirely peopled by such settlers.

The treatment of the first arrivals, though expatriated as 'the very dregs of society,' was, relatively to the times, unusually humane. This fact was due to the first governor, Captain Phil-

lip, who, though capable of severe disciplinary and deterrent measures, held enlightened views as to the prospect of a moral and industrial rehabilitation of his charges. Not only did he release them from their chains on the voyage out; on the day of formally establishing his government on land, he assured them of opportunities and assistance in any endeavours they might make to improve their position by conscientious work and good behaviour. On the other hand he hanged two ringleaders of a mutiny on board ship, and at a later date (1789), when the scanty and vitally necessary stores of the settlement were plundered, he summoned a court, hanged the ringleader, and committed the rest of the robbers to imprisonment on bread and water on a little island in Port Jackson which thus earned the appropriate name 'Pinchgut;' it was afterwards used for defence purposes, and is now known as Fort Denison. In spite, however, of these humane tendencies on the part of Phillip and of some, at least, of the later governors—such as Macquarie and Bourke—the treatment of convicts was marked, throughout almost the whole of the transportation period, by excessive rigour and frequently by flagrant brutality. For this there were several causes. The prevailing notion of the times was that the harsher the punishment the greater the deterrent, and that corporal punishment was the most effective; what would now be considered minor offences were then regarded as serious crimes; the situation of the community was one which called for safeguarding by rigorous discipline; officers and overseers were often petty tyrants of a merciless type; and, it must be added, many of the convicts were practically irredeemable criminals or incorrigible idlers.

The infant community consisted of the convicts, a military guard, and the officers of the government. To these there were gradually added a number of free settlers. In the earliest days it was difficult to maintain the colony in bare existence; it could not produce sufficient food-supplies for its own support, and shortages of provisions were often occasioned either by official neglect or by the delays and disasters of ships. These circumstances, combined with the severity of the punishments and the lawless temperament of many convicts, led to frequent outbreaks of insubordination, robberies, and daring attempts at escape. Several such attempts were successfully made in the early part of 1791. Apart from endeavouring to reach Java by sea, a strange notion prevailed among the prisoners that China could be reached by a journey overland, and the commissary's report for 1792 states that, of the number who deserted the settlement to seek that country, 44 men and 9 women had disappeared to perish or wander in the bush. Other escapees stole vessels from their anchorage, and, though some were recaptured, others became pirates or roamers in the South Seas.

During this period the work performed by the convicts was mainly building, clearing and cultivating, chiefly in the neighbourhood of Parramatta. In the agricultural domain the labour was not too exacting. In 1792 Phillip writes that the hours are only from 5 to 9 o'clock in the morning and from 4 to half-past five in the afternoon. In other respects attempts were made towards a normal life. Convicts and ticket-of-leave men were encouraged to marry. 'Emancipists' (q.v.) and expirees were permitted to take up small blocks of land for their own use. In this manner many 'first fleeters' settled along the newly discovered Hawkesbury River. Meanwhile free settlers were encouraged to apply to the government for the services of convicts, and of the women so engaged, originally as domestic servants, some became the wives of the male servants. Nor were convicts always kept at arm's length by the free. Thus they were permitted to join in public celebrations, and on the King's birthday in 1789 the first play performed in Australia (Farquhar's *Recruiting Officer*) was enacted by convicts (see DRAMA). The conditions of the convict system after the departure of Governor Phillip varied with the character of the governor, the supervision of the home authorities being necessarily nominal. The insufficiency of the information which they obtained made necessary the appointment of special committees in 1812 and 1837, and of a commissioner in 1819, to investigate the system in operation; and their reports, supplemented by official and private correspondence, give a fairly clear idea of the conditions under which convicts laboured until the end of the thirties.

The normal proceedings on the arrival of a transport in Sydney harbour were as follows. The convicts were first classified, not according to their previous record of character (except in so far as the surgeon superintendent might make such report), but according to their age and trade. As late as 1834 Bourke complained of the complete absence of data, apart from length of sentence, on which a proper classification might be made; he therefore welcomed an announcement from the colonial office in that year to the effect that a revision of the system in this regard, including classification in England, was contemplated. But about that time there were four political heads of the colonial office in 18 months, and the proposed revision was forgotten. Mechanics were generally reserved for government employ, and as many other convicts as might be required for public works. In Sydney before 1819—when the convict barracks were constructed—there existed no public place for lodging or temporary confinement of male prisoners on government work, and they were therefore released from service at 3 p.m. to find means to pay the expenses of private lodging. After the establishment of the barracks, government convicts who were still permitted by reason of good conduct or family ties (594 in 1819) to have private lodgings were obliged to work the full day, but were free on Saturday. Their clothes and food were provided by government; after the first years of shortage these were sufficient and good. The chief spheres of employment of such convicts were on public works, in the marine and survey departments, in the constabulary, in the households of government officials, and at the agricultural establishments, of which there were three under Macquarie—Grose Farm (now the site of the university of Sydney), with accommodation for 160 men and boys; Longbottom (between Sydney and Parramatta) with 110 men; and Emu Plains with 269. The convicts were lodged in wooden or bark cottages, each being permitted to build a separate one for himself. Convicts in government employ were generally divided into gangs, each with an overseer; every two or three gangs had a superintendent, frequently chosen from amongst the best-conducted convicts.

Convicts who were not taken into government service on arrival were either given tickets of leave or assigned to settlers. Tickets were usually granted to persons who had been in a 'higher station in life,' and had means of supporting themselves privately; they were obliged to pre-

sent themselves periodically before the magistrates, but were otherwise free to work on their own account. Convicts assigned to settlers were clothed, supported, and lodged by them; they worked either 'by the task' or for the same number of hours as the government convicts, and when the set labour was finished were allowed to work on their own account. Those assigned to well-to-do settlers were usually employed by their masters during their free hours at a rate of pay fixed by regulation; those assigned to poorer settlers, who could not afford to pay for extra time, were usually obliged to seek employment in the neighbourhood—a practice which led to irregular habits and discontent. In 1838 in New South Wales an assigned convict was entitled to a weekly ration of 12 lb. of wheat (or its equivalent in flour); 7 lb. of mutton or beef or 4½ lb. of salt pork; 2 oz. of salt, and 2 oz. of soap. For clothing the annual dole was 2 frocks or jackets, 3 shirts, 2 pairs of trousers, 3 pairs of shoes, and a hat or cap. In Tasmania the allowance was somewhat more liberal. Sir William Molesworth was told by a settler that he had assigned to him four convict servants, one transported for forgery, one for burglary, one for attempted murder, and one for a bestial offence. The welfare of the assignees depended upon the character and temper as well as upon the social position and occupation of the master. The inevitable inequality in their lot was emphasized by both Bourke and Gipps. Bourke, denying the charges made in England that their life was 'one of ease and plenty,' wrote: 'Although the condition of the convict is that of a slave, it has not been thought desirable to give to the master a power of personally inflicting punishment; a most extensive summary jurisdiction is, however, given to the magistrates, who (with the exception of those who are stipendiary) are always themselves settlers directly interested in maintaining the strictest subordination, and in exacting the most laborious exertion which the law permits on the part of the assigned servant.' Bourke did impose restrictions on magistrates in respect of the number of lashes which they might inflict, but the result was a petition from a number of landowners and magistrates to the King against such leniency. He also incurred hostility by establishing a board for the more equitable distribution of convict labour, and by his readiness to receive petitions from convicts as well as from settlers. On the other hand, in the service of humane masters the lot of the assignee was as happy as the system would allow. Gipps, for his part, declared that assignment was 'the greatest and the worst of lotteries.'

Female convicts on arrival were given tickets of leave—if they had husbands in the colony, or other means of supporting themselves and any children dependent on them—or assigned as domestics to officials or settlers, or sent to the factory at Parramatta. Before 1819 the condition of the factory was most unsatisfactory. Accommodation was provided for less than a third of the women sent to the town, and the remainder were obliged to find lodgings privately, frequently by cohabiting with male convicts or poorer settlers. In 1812 Macquarie had suggested that work at the factory should be much extended to accommodate more of the women, whom it was sometimes difficult to place, and proposed that a new factory should be erected. This factory, built in 1819, was inefficiently managed until the mid-thirties and had, as the select committee of 1837-8 pointed out, more of the character of a lying-in hospital than of a prison or a reformatory. Before his departure for New South Wales Gipps was authorized to reorganize the management, and soon after reaching the colony he made provision for separate confinement and for the introduction of industries. The dressing, and manufacture into nets, of New Zealand flax was introduced but abandoned, owing to the lack of a market for the product; needlework and washing for private persons (as well as on government account) was also organized, and the convicts were permitted to retain part of the money earned by their work as an encouragement to good behaviour.

There were, of course, wide differences of character among the convicts. The report of the select committee of 1837-8 referred to convicts in general as 'the very dregs of society,' and all the witnesses agreed that the conduct of the females was 'as bad as anything could well be.' On the other hand John Hunter—who had been a governor—told the committee of 1812 that 'there are many men who have been convicts, and are now settlers, who are as respectable as any people who have gone from this country.' Well-conducted convicts usually obtained a ticket of leave after 4, 6, or 8 years, if their original sentences had been for 7 years, 14 years, and life. If they married and showed themselves able to support a family, tickets of leave were granted more freely, and they had little difficulty in obtaining good wages, often with the government as constables, overseers, etc. Emancipation, too, was within reach of those worthy of it (see EMANCIPISTS). On the whole, however, the system was not conducive to moral regeneration. At its worst, as Molesworth said, 'it degraded the human being into a brute, destroyed his reflecting powers and left him no other thought or wish but the immediate gratification of his appetites.' Drunkenness, neglect of work, and theft were common. Concerted action among the convicts was always to be feared, though the lack of cohesion among them usually frustrated any planned riots. The only serious outbreak in New South Wales was that in 1804 among the Irish political prisoners, who had a legitimate grievance in that the records of their convictions were not forwarded to the colony. The trouble at Bathurst in 1830 was an ebullition of convict bushrangers (see BUSHRANGING), rather than an organized rebellion. Attempts at escape were less frequent than might be expected—owing, no doubt, to the fate that usually befell escapees. In Tasmania, for instance, between 1822 and 1827 116 convicts absconded from Macquarie Harbour; and of these 8 are known to have been murdered, 6 eaten by their companions, 16 hanged for murder or bushranging, and 2 shot by the military. Most of the others are supposed to have perished in the wilds.

Whatever the offence, punishment was immediate and severe. The lash was its most frequent instrument, and flagellations at the triangles were brutal in the extreme. Hardened assigned servants were returned to the government, and were then either worked in chain-gangs or sent to a penal settlement. The first penal settlement to which convicts were retransported for offences committed in the colony was Norfolk Island; when in 1806-7 it was temporarily abandoned, they were sent either to Tasmania or to the Hunter River—where they worked at lumbering, or procuring lime from sea-shells, or in the much dreaded coal-mines. The Hunter River station had its disadvantages as a place of punishment. It was the obvious destination of

convicts who had had mining experience in England, whether or no they were reconvicted in the colony; coal-mining suffered if only hardened offenders were set to the work, and the experienced miners suffered unjustly if they were intermingled with reconvicted men. When free settlement began to extend along the Hunter, it was found necessary to occupy Port Macquarie (1821) as a penal settlement for reconvicted offenders. Commissioner Bigge suggested an improved method of convict classification, and proposed that only convicts of good character should be left in the settled districts, the rest being moved to a new settlement at Moreton Bay, Port Curtis, or Port Bowen. The retention of the settlement at Port Macquarie was in his opinion a hindrance to the development of its rich hinterland by free men. The colonial office preferred the reoccupation of Norfolk Island to the establishment of fresh penal settlements on the New South Wales coast, but Governor Brisbane pointed out that, if Port Macquarie was to be abandoned, the island was not big enough to contain all who under the new classification must be removed from New South Wales. In 1825, therefore, he developed a scheme by which Port Macquarie would be the prison for those guilty of 'first grave offences; Moreton Bay for runaways from the former, and Norfolk Island as the *ne plus ultra* of Convict degradation.' Earl Bathurst, adhering to Bigge's opinion, proposed in 1826 to occupy the shores of Shark Bay on the western coast as a prison for offenders in the second stage of Brisbane's scheme, making Moreton Bay the first stage, and leaving Port Macquarie open for free colonization: and, though the occupation of Shark Bay did not materialize, Darling managed, by withdrawing the lesser criminals to serve in road-gangs, to empty Port Macquarie until the remnant could be shifted without inconvenience to Moreton Bay. This process was completed in 1830, and reconvicted women who had formerly been sent to Port Macquarie were now sent to Moreton Bay until 1839, when the female establishment there was broken up preparatory to the removal of all convicts from that centre (see BRISBANE). But although settlers were now allowed to occupy land in the neighbouring district, the station at Port Macquarie was not altogether disused; Governor Bourke at first sent to it all educated convicts as they arrived in the colony, and afterwards (about 1835-6) used it as a reformatory 'out of the way of harm' for 'persons of feeble bodily health or incorrigible petty thieves.'

Meanwhile in Tasmania Governor Sorell had in 1818 employed Macquarie Harbour for the reception of reconvicted persons and Arthur in 1832 moved this settlement to Port Arthur. The conditions in Norfolk Island and Port Arthur, to which the worst type of male convicts were sent, are described as being of unmitigated severity. In these penitentiaries there were no other inhabitants than the prisoners and their guards and keepers, and none but official communications were permitted with the settled districts. No female convicts were sent there. The work was of the most incessant and galling description, and the lash and irons were in frequent use. It was considered unsafe to trust the men with knives, and they must perforce tear their food with their fingers. When not actually at work, and during the whole of Sunday, they were confined in a yard surrounded by a high wall. The moral condition of the prisoners was atrocious. Styles, a resident chaplain at Norfolk Island, officially reported that 'blasphemy, mutual hatred, and the unrestricted indulgence of unnatural lust are the things with which a short residence in the prison wards must necessarily familiarise the convict.' In the opinion of Chief Justice Forbes 'the experience furnished by these penal settlements has proved that transportation is capable of being carried to an extent of suffering such as to render death desirable, and to induce many prisoners to seek it under its most appalling aspects.' A similar statement was made concerning Norfolk Island by Dr. Ullathorne (q.v.). Bourke reported on 5 November 1837 that much of the atrocious crime prevalent at the island during the early thirties was due to the hope the criminal entertained of being taken to Sydney for trial; when it was made possible for the authorities to try capital offences on the island itself, conditions became quieter. Arthur also mentions prisoners at Port Arthur who committed murder in order to be sent to Hobart for trial. It is little to be wondered at that daring attempts at escape were made, despite the isolated position of Norfolk Island and the soldiers and ferocious dogs who guarded the narrow neck of land at Port Arthur. Attempts at mutiny were not uncommon; Norfolk Island, indeed, was on one occasion (in 1834) in the hands of the convicts, but in the end 9 were killed, 29 condemned to death, and 11 executed.

It is obvious that in the convict-system in operation until the end of the thirties, there was abundant room not only for displays of official vindictiveness but also for the practice of many forms of corruption. Apart from congenital tendency to cruelty, injustice, or dishonesty, the very association with so large a criminal element, and with barbarous methods, demoralized guards, gaolers, overseers, and police. It also demoralized many in higher places who were in a position to award favours and reap profits therefrom. A police which was partly composed of convicts had plentiful opportunities for obtaining bribes through connivance, for extorting blackmail, and for bringing false accusations. In assigning convicts among the competing settlers it was easy for officials to show favouritism. Wives or others who, themselves free settlers, had followed convicted husbands or relatives, and who were possessed of means, could indirectly purchase the assignment to themselves of those husbands or relatives, sometimes out of the produce of the very offence which had caused the conviction. Warders allowed convicts to quit barracks at night in return for a share in the booty which they might make by plunder.

As to the behaviour of convicts before and after emancipation, contemporary statements are contradictory, being coloured by different policies, interests, and sympathies. Phillip states that the convicts of the first fleet were 'quiet and contented, though there are among them some complete villains.' Many, undoubtedly, were hopeless criminals; nor must it be overlooked that, in many cases in which the specified charge brought before the British benches was trifling in itself, the magistrates must have been aware of much collateral delinquency. In both New South Wales and Tasmania wanton cruelties were perpetrated on the aborigines by convict shepherds. Convicts employed on the roads or in other non-domestic work often co-operated with convict servants in committing burglaries and thefts. From about 1827 men who had escaped from the road-gangs frequently indulged in highway robbery and

'bushranging.' Of emancipists or expirees the larger proportion, according to the Report of 1838, were profligates, dissipated, cattle-stealers, receivers of stolen goods, or otherwise worthless characters. Arthur described the 3000 of them in Tasmania as 'the worst class in the colony.' The effect on the community in general was of the worst, and of Sydney in 1836 it is stated that 'more immorality prevailed than in any other town of the same size in the British dominions.'

Nevertheless, considerable qualification must be made to these bald statements. Hunter's opinion has already been quoted. In 1827 Allan Cunningham wrote that the emancipists were 'the most useful and enterprising part of our community.' In 1820 Macquarie said that they 'have made wonderful efforts,' and he preferred them in 'both moral and political' character to the free settlers who 'struggle for their depression.' His successor, Brisbane, declares in 1823 that 'it is not the convicts who give me trouble, nor the emancipated convicts, who have uniformly behaved well, but it is your settlers and good people who call themselves gentlemen, who generally do all they can to thwart the Government.' The last words, it is true, betray the bias of a governor who resented the efforts of the free settlers to thwart his autocracy, and neither Macquarie nor Brisbane can be acquitted of prejudiced exaggeration. But the more temperate statement of Hunter cannot be thus set aside. Moreover the worst and most hideous evidence given before the committee of 1837-8 (which mainly determined the character of the Report) referred to conditions existing at Port Arthur and on Norfolk Island: and these, it must be remembered, were isolated settlements of supposedly hardened criminals, completely detached from ordinary life in the Australian colonies. The horrors depicted by Marcus Clarke in *For the Term of His Natural Life* are as little typical of Australian conditions—even of the conditions that affected convicts in general—as those catalogued by Charles Reade in *It Is Never Too Late to Mend* are of normal English society.

The strong and ever-growing opposition of the Australian colonies to the continuance of the convict system, and the recommendations of the committee of 1837-8, forced the British government to reconsider the whole subject of convict management. In 1839 it was decided to terminate as quickly as possible the system of assignment, and on 11 May Gipps was informed that convicts would in future be sent only to Tasmania and Norfolk Island. At the island the first experiment in reform was to be made under the direction of Alexander Maconochie (q.v.), whose schemes of reformatory—as opposed to vindictive and exemplary—punishment had much impressed the parliamentary committee. These schemes and the principles on which they were based are so important in the history of penal legislation that some space must be devoted to them here. In Maconochie's opinion, the method of remitting punishment was the most serious defect of the old system, as it gave much scope for favouritism and produced a feeling of uncertainty which militated against reform. The actual duration of sentences should be determined not by time but by good conduct, which should be definitely and regularly measured by a system of marks. Each prisoner should, unless misconduct were proved against him, automatically receive a fixed number of marks each day for his labour. These marks would be a form of wages, exchangeable for indulgences such as extra rations, or even redeemable in terms of money. Indeed, it would be preferable if no rations were issued at all by the government; the prisoners should be given marks enough to enable them (*a*) to purchase necessities and (*b*) to leave a balance that might accumulate for the purchase of freedom (for the remission of a sentence was to depend absolutely on the accumulation of a number of marks fixed according to the length of sentence). By thus exercising choice between an indulgent expenditure of marks in the present and a more rapid remission of sentence in the future, the prisoner would bear a continuous responsibility that would assist him to reform, for which there was no provision at all under the existing system. Maconochie admitted the need of a preliminary period of solitary confinement, but laid most emphasis on the subsequent period of mutual responsibility. Prisoners would be divided into small groups, the members to be responsible for each other's good behaviour. Military police and prison overseers were to be abolished. As the object of discipline was reform, and the chief means education, teachers must be appointed to train the prisoners in industries which they could subsequently pursue on readmission to society—hence the necessity of establishing a penitentiary on a site affording a variety of occupations. Throughout the period of imprisonment there should be a progressive relaxation of discipline, to encourage the prisoner to make a voluntary effort to resist temptation; and to this end Maconochie also opposed the complete separation of the sexes and of the young from the old.

The colonial office announced that for the future on Norfolk Island the actual length of sentence would be determined by a prisoner's good conduct. This did not commit anyone to approval of details of Maconochie's system; but it was suggested to Gipps that he might be a suitable superintendent of the island under the new conditions. Gipps agreed, and Maconochie accepted the appointment, though he considered Norfolk Island ill-suited to the experiment—owing partly to the lack of variety of occupation. A greater difficulty lay in the fact that the experiment was only to be tried with prisoners sent from England for the purpose, whereas there were already on the island about 1200 'twice-convicted' prisoners from New South Wales. This number, however, would gradually decrease as the colonial sentences terminated, for it was agreed that in the future colonially convicted men should not be sent to Norfolk Island. In the meantime, two systems of management would have to be operated, unless Gipps permitted Maconochie to bring them all within the scope of the new experiment. This Gipps refused to do; but he made the position easier by appointing an assistant superintendent to take over the more routine duties of the old establishment. Gipps also refused to allow the exchange of marks for indulgences until at least two years of the original sentence had been served, unless Maconochie found such exchange absolutely necessary to give his experiment a fair trial. Though Gipps had little faith in the success of the new system of management, he was prepared, since it had been sanctioned, to give Maconochie such assistance as he deemed practicable; he authorized, for instance, the expenditure of £50 on books and £143 15s. on music and musical instruments, as Maconochie attached great importance to the early formation of a library and to the cultivation of a taste for music among the prisoners. Maconochie

chie took office early in 1840; in March 1843 Gipps made an official visit to the island, and his report is a valuable commentary on this official experiment in penal reform.

Of Maconochie's success in managing the 'old hands' (of whom 876 were still on the island in 1843) Gipps wrote with almost unqualified approbation. Sympathetic control and the relaxation of discipline to permit the use of knives, walking through the island in leisure hours, bathing in the sea, a separate garden, etc., had had a markedly humanizing effect. The services in the Protestant and Roman Catholic chapels, for the building of which Maconochie had been reprimanded, had also contributed to this result. But the chief object of the visit was to enquire into the new experiment. Of the 679 'new hands' 75 had died of dysentery, aggravated by the deprivation of wheaten bread against which Maconochie had pleaded without avail. Of the remainder, 509 had won island tickets of leave in exchange for accumulated marks, varying from 6000 to 8000 according to the length of sentence. Each ticket-holder worked as formerly for the government, and received a daily ration and marks varying from 22 to 30 according to the nature of the work performed. The original scheme for the redemption of marks by money had not been put into effect, chiefly because of the opposition of Gipps, who feared an unlimited increase in expense. After the day's task-work was completed, ticket-of-leave holders were allowed to employ themselves to their own advantage. They lived out of barracks; some had been placed in small groups on farms of from 6 to 10 acres. For each acre cultivated they paid a rent of 12 bushels of maize, or one-third the average crop per acre raised on government land; uncleared land brought into cultivation was free of rent for the first year. Maize, sweet potatoes, potatoes, cabbages, tobacco, etc., were grown, and pigs and poultry had been procured from the superintendent in exchange for marks. In 1843 there were 27 such farms, worked by 78 persons, and Gipps admitted that this part of the experiment had been attended by considerable success. Many 'new hands' had acquired marks in excess of the number required for their freedom, but—owing to the difficulties of placing the men in Tasmania (it had been agreed that none of the 'new hands' should enter New South Wales)—their expectations had not so far been fulfilled. For this situation Gipps largely blamed Maconochie, first for not having adopted a preliminary punitory period, and secondly for having been so lavish in the distribution of marks as to allow their accumulation in excess of the number fixed for freedom before any preparation had been made for disposing of the men when free. Naturally interest in the acquisition of marks had fallen off, as was evidenced by an increase not so much in crimes of violence as in cases of gambling, unnatural offences, etc. Maconochie admitted failure in the case of the groups mutually responsible for the conduct of their members. The mark-system as a whole Gipps considered weak; to produce their full effect marks should be distributed daily, and should vary in number according to a man's conduct and work. Maconochie did not permit an overseer to deprive a man of his daily allowance of marks without bringing him to court; as a result, for months together the same men received the same number of marks though it seemed scarcely possible that they had behaved equally well throughout the period. Gipps also objected to the differential value given to various classes of work, which made it possible for a skilled artisan to secure his freedom earlier than an unskilled labourer. Gipps was convinced, too, that the productive labour of the 'new hands' was much less than that of the 'old.' The cost of each convict to the government had increased during the three years of Maconochie's control to £13 3s. 11d. per annum, whereas in the previous triennial period it had been £10 18s. 4d. This increase was exclusive of the increased cost of staff, etc. Though recognizing that the decision as to the continuance or abandonment of the experiment rested with the British government, Gipps admitted that he would be sorry to have the experience gained by Maconochie during his stay at the island wholly thrown away.

To keep faith with the 'new hands' who had accumulated the number of marks required for their freedom he was prepared to remove them to Tasmania on tickets of leave or conditional pardons in March 1843, although he believed that the change would not in general improve their economic condition; still, the 'new hands' were as eager as the 'old' to get away from the island, chiefly because of their enforced isolation from society. 'The yearning of their hearts' he wrote 'towards society is indescribable; it constitutes their torment; it is a punishment greater than the lash, or any other that man can inflict upon them.' Action was delayed, however, until the following spring, owing to the difficulty of finding employment for the men during the winter.

But the colonial office had already decided to relieve Maconochie of office, not because of any reflection on his character—indeed, Stanley ascribed to him 'a most earnest solicitude for the welfare of a class of society whose claims to compassion and benevolence have seldom been so keenly felt by persons in his station of life'—but because it had worked out a new scheme of convict management. From reports received in England it was generally believed there that 'what may have been gained by the relaxation of discipline in an increased mildness of demeanour has been more than compensated by the growth of moral and social evils of another kind.' Moreover, Maconochie's plans laboured under the serious disadvantage of 'impairing the dread of punishment of transportation' in Great Britain, and of involving the government (contrary to his own expectations) in an indefinite and increasing expense. The basic principle of the new system was that every convict must actually undergo punishment, without either pardon or mitigation, for some predetermined period proportioned to the length of his sentence. There were to be five successive stages of punishment, discipline being relaxed at each stage until the convict was competent to receive a pardon, either absolute or conditional; but he would never be entitled to demand it as of right. The first stage involved confinement in a penitentiary under severe discipline. Convicts sentenced for less than 15 years would serve this period of confinement in England; convicts with a longer sentence would be sent direct to Norfolk Island—which was to be detached from New South Wales and put under Tasmania in order to centralize control. Convicts already on the island were, as a preliminary measure, to be granted the satisfaction of any reasonable expectations they might have formed under Maconochie's supervision. The actual length of time to be served on the island

would be not less than two and not more than four years, and could not be abridged; good conduct during this period would be rewarded in subsequent stages of punishment. It was anticipated that not more than 1000 convicts would be sent to the island yearly. The second stage would involve work for not less than one nor more than two years (except in cases of misconduct) in one of the probation-gangs to be assembled in Tasmania; these would be subdivided into two or three groups to permit the grant of indulgences to the well-conducted, would consist of from 250 to 300 men, and would be employed at hard labour in government service—usually in the unsettled districts. Great importance was laid on the provision of religious and other instruction. It was anticipated that at any one time 8000 convicts would be employed in these gangs.

Having passed satisfactorily through the probation-gang, the convict would become the holder of a probation-pass, and might then engage in private service for wages approved by the government. Pass-holders would be classed according to conduct, the first class receiving only half their wages, the second class two-thirds, and the third class the total amount. The balance must be deposited by the employer in the savings-bank, to be paid to the convict when he obtained a ticket of leave; but, if a convict forfeited his probation-pass by misconduct, the deposit would become the property of the crown. Until private employment offered, pass-holders would work for the government, receiving rations and clothing but no wages. There was no limit to the period served as a pass-holder—except, of course, the length of sentence. The transition from this stage to that of a ticket-of-leave holder could not be made before half the original sentence had expired, exclusive of any extra period served in the first and second stages for misconduct. The status of a ticket-of-leave holder would be similar to that already obtaining. The final stage was that of a conditional or absolute pardon, which was exclusively the crown's prerogative.

The position of female convicts was admittedly different from that of males. Though the government recognized the evils arising from the disproportion of the sexes in Tasmania, they were not prepared to continue the transportation of women unless the 'additional incentives to vice' prevailing under the existing system were replaced by facilities for reformation. There was to be no further assignment of female convicts. The female factories at Hobart and Launceston—which were 'exceedingly discreditable . . . . subjecting every class of offenders to the contamination of mutual bad example, in rooms so crowded that according to very high authority it has occurred that the whole of the prisoners have been unable to lie down at one time and that a portion have been left standing while others rested'—were to be investigated with a view to increasing the accommodation, improving the classification, and effecting a more complete separation between the different classes of convicts. The women were to be encouraged to work for probation-passes, and ultimately for tickets of leave. New arrivals in the colony were not to be sent to the factories; for their reception the governor was to have constructed, at least 20 miles inland from Hobart, a penitentiary on the most approved plan capable of containing at least 40 persons. The 'new reformatory system,' which was to be introduced on the transports, was to be continued after arrival. After six months in the penitentiary women might receive probation-passes, providing they had not misconducted themselves in the meantime; pass-holders would be competent to advance through the subsequent stages of punishment on the same basis as males. It was hoped that respectable citizens would be prepared to hire servants from the penitentiary. If holders of probation-passes misconducted themselves, they would not be returned to the penitentiary but would be sent to a factory.

The whole penal establishment in Tasmania and Norfolk Island was to be put under the charge of a comptroller-general of convicts, sent from England and paid out of British funds, who would communicate with the governor direct and be practically a colonial secretary for this branch of the service. Before the proposed scheme could be put into operation, it was necessary to reserve to the Queen alone the prerogative of granting a pardon, the governor being empowered to grant remissions and mitigations of punishment; this was done by act of parliament (6 Vic. c.7).

By 1846 it was generally admitted that the new system had failed, not so much from any inherent weakness as from the impossibility of putting it into complete operation while four to five thousand convicts were being poured into Tasmania every year. On 1 January 1846 there were 29,949 convicts in the colony; of the 10,480 serving in probation-gangs, 3852 would receive probation-passes during the year and be competing for private service, although 3509 out of the 12,240 existing pass-holders were still unable to find work. On 30 September 1846 Earl Grey admitted that it had been found impossible to maintain proper discipline in the gangs because there were too few officers and overseers. Proper work could not be found for the gangs, nor could there be sufficient inducement to good conduct while so many pass-holders were perforce retained at government hiring-depots. Ticket-of-leave holders who were dependent on wages for subsistence had suffered great distress. To relieve the situation, it was decided to suspend the transportation of males to Tasmania for at least two years. Early in the year one of the most experienced officers responsible for convict discipline, John Stephen Hampton (q.v.), was sent to the colony as comptroller-general, and it was hoped that he would bring some order out of chaos.

Grey also proposed modifications in the existing system of management. He disagreed with Maconochie's contention that all punishment that was not reformatory was vindictive; on the contrary, 'the suffering imposed by society at large on some offending members in order to deter others from committing the same crime from a dread of subjecting themselves to the same condemnation, is the great and primary end of punishment.' Nevertheless, considerable advantages were to be derived from a more extensive and methodical application of the principle of task-work implied in the system of marks. He proposed, therefore, that the 'days' to be spent in the probation-gang should be measured by work. The task set for each day should be so fixed that a man of average power, by working hard, could complete one and a half or one and three-quarters days' work within the time, and might use this extra work to reduce the period to be served in the probation-gang, or exchange it at a fixed monetary rate for luxuries. This task-system, which was already in

operation in Bermuda, was in 1846 introduced in Tasmania, and continued until the break-up of the convict system with remarkably good results.

Meanwhile unsatisfactory reports of the conditions prevailing at Norfolk Island, where long-term prisoners were serving the first period of confinement, had reached both the governor of Tasmania and the colonial office. Investigation showed that the prisoners were on the verge of open mutiny, and Eardley-Wilmot at once suspended the superintendent, Major Childs, whose incapacity was chiefly responsible for the condition of affairs. Pending instructions from the colonial office, the police magistrate of Hobart was despatched to take over control; but before his arrival the threatened outbreak had occurred, with fatal results. The colonial office had already decided that the establishment at Norfolk Island should be immediately disbanded, but the governor on Hampton's advice recommended that it should be retained as a penitentiary for colonially convicted prisoners; for the practice of sending this class to the island, which had been suspended during Maconochie's term of office, had been resumed, and the impossibility of segregating the two classes of convicts had been partly responsible for the mutiny. This recommendation was accepted, and Norfolk Island ceased to be a place of first confinement for long-term prisoners. Indeed, the British experts on penology had come to the conclusion that no more convicts should be sent overseas until they were fit to receive tickets of leave on arrival in the colonies; but in 1852, before any large scheme on this basis could be developed, it was decided in deference to colonial opinion to terminate all transportation to eastern Australia. The convict system therefore died out as the sentences of men already in the colonies expired.

The system under which convicts were supplied to, and handled in, Western Australia is dealt with in the article on that State. T.G.T.

Convolvulaceae, a large family of herbs or shrubs, often twiners, widely dispersed, but most abundant in warm countries. The fruit is either capsular or succulent. Fourteen genera with 72 species are indigenous to Australia. The genus *Convolvulus* has 4 indigenous species, trailers or twiners. *C. soldanella* is a prostrate trailer on sandy sea-coasts in many parts of the world, and is regarded as a useful sand-binder. The genus *Evolvulus* is found mainly in tropical America; the only species indigenous to Australia, *E. alsinoides,* which ranges across the continent, extends also to tropical America and Asia. Its stalks, leaves and roots are reputed as remedial in cases of dysentery and fever. The genus *Cuscuta* (Dodder) has numerous species, chiefly in tropical regions; 3 are indigenous to Australia and one, *C. tasmanica,* is limited to Victoria and Tasmania. See IPOMAEA.

Cooee-bird. See CUCKOOS.

Cook, JAMES (1728-1779), was born at Marton-in-Cleveland (near Middlesborough in Yorkshire) on 27 October 1728. His father was then a farm-labourer, but soon after was made working bailiff to a farmer at Ayton. The boy worked on the farm, was for a short time stable-boy at Ayton Hall (see DUCKETT, SIR GEORGE), learnt a little at the village school, and at 17 was apprenticed to a grocer at Staithes near Whitby. The sea called him, however, and the agreement was soon cancelled in order to re-apprentice him in 1746 to John Walker of Walker Brothers, Whitby shipowners, under whom he served for nine years (three as apprentice) in vessels trading to Newcastle, Norway and the Baltic. During this apprenticeship Cook, as was the custom of the period, lived in his master's house when not at sea. The home life with John Walker seems to have had a large share in moulding his future, for the long evenings were spent in improving his book-knowledge, with the constant help of his master. It was then he acquired the grounding in navigation that was afterwards to stand him in such good stead; the North Sea and its seamen, then as now, provided a school of seamanship from whose rough but efficient teaching there was no escape. When the Seven Years' War broke out, Cook was mate of the *Friendship,* lying in the Thames; he volunteered for service, was promptly entered aboard H.M.S. *Eagle* as A.B., and 35 days later was rated master's mate. There was nothing unusual in this rapid promotion, for men combining first-class seamanship, fair education, a decent knowledge of navigation, and moderate sobriety of conduct were not plentiful. In the *Eagle* he served under Hugh Palliser, also a Yorkshireman, and saw fighting at the capture of a French East Indiaman; he was next transferred to the *Solebay* with a master's warrant and a recommendation from Palliser, and then to the *Pembroke,* in which he was present at the operations of 1759 on the St. Lawrence and the attack on Quebec. On 23 September 1759 he was transferred to the *Northumberland,* and while in her was particularly mentioned for 'indefatigable industry in making himself master of the pilotage of the River St. Lawrence.' In such leisure as he could command he was still working at his books, and during this period first studied Euclid. The *Northumberland* was afterwards present when St. John in Newfoundland was recaptured from the French; here also served another James Cook, first in the *Mercury* and then in the *Gosport,* with whom the circumnavigator has been frequently confounded. Cook's good work in these waters induced Admiral Lord Colville to commend him highly to the admiralty as a man of 'genius and capacity . . . well qualified for greater undertakings of the same kind'—i.e. survey work. Consequently in 1763 he was appointed to survey the coast of Newfoundland and the neighbouring islands—a task which lasted, with intervals for refitting in England, from May 1763 until November 1767. It was made at first in small vessels attached to the flagship, but in April 1764 Cook was given his first separate command in the schooner *Grenville,* with a crew of one mate, a servant and seven men. The charts he made, says the hydrographer Wharton, are not yet wholly superseded. While on the survey, he made on 5 August 1766 a good observation of an eclipse of the sun which brought him under the notice of astronomers and of the Royal Society.

In 1767 the Royal Society began to make preparations for observing in several parts of the world a transit of Venus across the sun's face that was due to occur in June 1769. For the South Seas Alexander Dalrymple was recommended; but he demanded full control of the ship set apart for the service, and Hawke (then first lord of the admiralty) refused point-blank to give the commmand of a king's ship to a man not a king's officer. At the suggestion of Palliser and of Stephens (one of the secretaries of the admiralty) Cook was chosen, and on 25 May 1768 commissioned lieutenant to
